Figure 5 shows the fractional change in annual integrated direct solar radiation penetrating the stratosphere at the indicated latitudes for the two cosmic-ray flux enhancements. In the case of the 100-fold enhancement, the integrated radiation is increased by a few tenths of a per cent, as the increased absorption by NO_2 is not sufficient to compensate for the decreased ozone absorption. In the case of the 1,000-fold enhancement, however, the increase in NO_2 absorption overwhelms the decrease in ozone, and the integrated solar radiation is decreased by several per cent at all latitudes.

Fig. 5 Direct solar radiation penetrating the stratosphere integrated over one year and over all wavelengths.

In attempting to estimate the climatic effects of these changes in integrated solar radiation, it is important to realise that they are not equivalent to changes in the solar constant of the same magnitude. The radiation that is prevented from reaching the lower atmosphere in the 1,000-fold enhancement case is absorbed in the stratosphere, where it greatly increases the heating rate and thus the temperature, leading to a substantial increase in stratospheric thermal radiation. This partially compensates for the deficit in direct solar radiation at the surface. There will also be a change in the effective albedo of the lower atmosphere as a result of the change in spectral composition of the incident radiation.

These perturbations in the terrestrial radiation budget will certainly be accompanied by important changes in the dynamic coupling between the stratosphere and troposphere, and a calculation of the full climatic consequences is not yet possible. Estimates made with a relatively simple radiative-balance model, however, predict a drop in global average surface temperature of about 3 K for the 1,000-fold enhancement case. The complexities of radiative feedbacks are such that this figure is significant only as an indication of a major climatic perturbation, but is much larger than that estimated by Hunt¹¹, using a more sophisticated radiative-convective model. Hunt's calculation, however, included only the effects of the ozone depletion, and did not consider the much larger effect of the enhanced NO_2 that must accompany the depleted ozone.

Despite the qualitative nature of the estimated global cooling, some of the consequences are worth exploring. A 3 K drop in surface temperature, for example, would lead to a drop in global average atmospheric water-vapour content of about 20%, assuming a constant average tropospheric relative humidity profile as quoted by Manabe and Wetherald¹⁵. This would decrease the greenhouse effect, tending to decrease surface temperatures even more and would also lead to changes in cloud properties, with further climatic consequences. The reduction in water-vapour content might be expected to lead to widespread drought conditions, but might prevent the occurrence of a true 'ice age', as above-normal precipitation is probably required for the development of continental ice sheets.

Figure 6 shows the increase in the biologically effective UV radiation penetrating the stratosphere in the course of a year at the indicated latitudes for the two cases. These values were obtained by multiplying the integrated annual radiation at wavelengths between 280 and 310 nm by a 'biological effectiveness' factor¹⁶ derived on the basis of the absorption cross sections of protein and nucleic acids, and integrating over wavelength. Increases in UV dose by more than an order of magnitude are indicated, but these should be regarded with caution, as the effects of Rayleigh scattering by the lower atmosphere, which are substantial for UV wavelengths, have not been included. The results are thus only semi-qualitative, but indicate a severe increase in UV radiation levels.

Fig. 6 Biologically effective annual UV dose during periods of enhanced cosmic-ray flux. Quantity shown is the ratio of the enhanced dose to that received in present conditions. Transmission through the lower atmosphere has not been included in either enhanced or normal dose.

The reduction in visible radiation intensity resulting from the 1,000-fold enhancement case is also likely to have an effect on global photosynthetic activity, as noted previously by Crutzen and Reid¹⁷. Photosynthesis is most efficient at wavelengths in the blue (near 450 nm) and in the red (near 660 nm), and Fig. 4a shows a reduction in the important blue light of about 30%. The integrated annual radiation in this wavelength region received at the Equator is thus equivalent to that received in present conditions at 40° latitude, and the radiation received at 40° is equivalent to that now received at 60°. Coupled with the probable drought conditions resulting from the decrease in global temperature, a severe decrease in the abundance of plant life is probable. According to our present understanding of the terrestrial carbon cycle, the decrease in plant life would probably lead to an increase in atmospheric CO₂ concentrations, which in turn would tend to increase the surface temperature through the greenhouse effect. The temperature might become stabilised in this way at a value somewhat above that predicted in the absence of the biosphere, but with a globally reduced biomass.

A further perturbation to the biosphere might arise from the increased precipitation of fixed nitrogen on the surface of the Earth. The ultimate fate of fixed nitrogen diffusing into the troposphere from above is probably rainout leading to surface deposition. The model calculations show that the total downward flux of N at tropopause heights is about $2 \times 10^{10} \text{ kg yr}^{-1}$ for the 100-fold enhancement case and $2 \times 10^{11} \text{ kg yr}^{-1}$ for the 1,000-fold enhancement case. The former value is comparable with current estimates for the annual amount of nitrogen fixed in the atmosphere by lightning¹⁸, and the latter value is comparable to the total amount of nitrogen fixed by biological processes¹⁹. The addition of such large quantities of biological nutrient would have an impact on the biosphere that is not easily estimated.

Conclusions

We may conclude that passage of the Earth through a SNR would be likely to cause a prolonged period of harsh environmental conditions for the biosphere, including high levels of damaging UV radiation, cooler global temperatures and generally dry conditions (depending on how intense the cosmic-ray flux within the SNR becomes), and reduced photosynthetic activity. Whether or not these severe conditions would lead to major extinctions of animal populations is a matter for speculation. The evidence from the geological and fossil record is not clear, although McLean²⁰ has interpreted the Cretaceous-Tertiary record as supporting a global warming, rather than a cooling, as the cause of the terminal Mesozoic extinctions. If this view is correct, a nearby supernova event can probably be eliminated as the cause of these particular extinctions.

The probability of a nearby (within about 15 pc) supernova explosion is also debatable. At the low end of the scale, Whitten *et al.*¹⁰ have estimated a 1–5% chance of a supernova within 5–10 pc in a period of 10^8 yr . Data presented by Shklovsky²¹ lead to an estimated frequency of one in $1.5 \times 10^8 \text{ yr}$ at 15 pc distance, while Clark *et al.*¹² estimate one in 10^8 yr at 10 pc distance on the basis of the confinement of type 2 supernovas to the vicinity of the spiral arms of the Galaxy, and the regularity of the passage of the Solar System through these spiral arms. Whichever view is correct, a nearby supernova explosion is not a dim and exotic possibility when viewed in the geological time scale, but rather an event that may well have occurred several times within the 10^9-yr lifetime of the biosphere.

Finally, note that enhancements in cosmic-ray flux by a factor of 1,000 lasting for 1,000 yr would cause an enhancement in the average cosmic-ray flux over a 10^8-yr period of only 1%. Such events would therefore be quite consistent with evidence from lunar rocks and meteorites that the average cosmic-ray flux has varied by less than a factor of two over the past 10^9 yr (ref. 22).

The origin of labyrinth and tower karst and the climatic conditions necessary for their development

G. A. Brook

D. C. Ford

McMaster University, Hamilton, Ontario, Canada

A new karst style, labyrinth karst, is recognised in climates ranging from humid tropical to subarctic. In the late stages of evolution it is replaced by limestone towers indicating that tower karst is polygenetic, and not specific to the humid tropics as was once thought.

THE morphoclimatic principle that specific climates produce specific landforms has been more frequently applied in the study of karst (solutional) landscapes than in other branches of geomorphology. The impetus for its adoption came from pioneer studies of humid tropical karstlands in the 1930's¹. These revealed a wider variety of forms developed on a grander scale than elsewhere, and two broad karst styles—cone karst (Ger. Kegelkarst) and tower karst (Ger. Turmkarst)—that did not seem to develop in temperate or colder areas. In later work climate has been called upon to explain both areal and altitudinal variations in the character of karstlands. Despite reaction to what some consider as a grave overemphasis of climatic factors^{2,3}, the principle is still widely accepted. Central to that acceptance is the supposed humid tropical climaspecificity of the cone and tower karst styles, for which thresholds of temperature and precipitation have been proposed (Table 1).

In 1972–74 we explored and studied a complex and accentuated karstland at lat 61–62° N in the Nahanni area of the Mackenzie Mountains, Northwest Territories, Canada. Landforms are at an altitude of 1,000–1,300 m. The climate is of the subarctic continental interior type and there is discontinuous permafrost. Our findings have added to knowledge of karst styles and suggest that some relationships between karst morphology and climate be reassessed.

The Nahanni karst is dominated by a series of vertical-walled landforms which are linked in a simple yet remarkable developmental sequence^{12,13}. During early stages water draining underground via vertical fissures creates strings of solution dolines, circular to elliptical in plan view and cylindrical in depth (Fig. 1). By enlargement and coalescence along the fractures, strings of dolines are converted to intersecting networks of karst streets. As streets deepen and widen, the intervening rock ridges are dissected and ultimately destroyed. Replacing them are large closed depressions of angular planform and irregular distribution that we term 'karst platea'. Where insoluble sediment is carried to these depressions by allogenic streams, underground drainage becomes impeded and there is flooding after heavy summer rains. Floors are alluviated and the platea become small poljes. As platea and/or poljes expand, rock towers are left which rise from uneven karst margin plains. At this stage of evolution the landscape resembles a scaled-down version of the spectacular tower karsts of Puerto Rico or south

China. In the north of the Nahanni region karst streets, platea, and poljes form an intricate natural rock labyrinth (Fig. 2). Streets are as much as 185 m deep and 9 km long, and platea and poljes up to 125 m deep and 2–3 km long. Limestone towers with vertical to overhanging walls are up to 125 m high (Fig. 3).

We have identified karst landscapes like that of the Nahanni in several humid and seasonally humid tropical carbonate terrains. In south-west Celebes, Sunartadirdja and Lehmann¹⁴ describe

Fig. 1 The early doline stage of labyrinth karst development. Rappel Cenote is an elliptical-shaped doline 30 m deep. Even in summer drainage routes are blocked by subsurface ice so that ponds are common in such depressions.

karst streets 6–400 m wide, 50–200 m deep, and up to 8 km long. Where these intersect, depressions (platea) have developed. Several have been alluviated by influx of insoluble residue from nearby crystalline rock indicating that they are the embryos of future poljes. Scattered, isolated limestone towers are also common. Similar topography is found on many upland surfaces in Sarawak¹⁵. For example, at Subis joint-guided corridors (streets) are about 30 m apart and 3–150 m deep. At intersections depressions (platea) 5–180 m deep and 5–500 m across are common. At an advanced stage of dissection rows of tall 'needles' (towers) are all that remain between the streets. Stereo photographs (Plate 2 of ref. 15) reveal a rock labyrinth nearly identical to that in the Nahanni. Deep, intersecting karst streets several kilometres long are reported in the Star Mountains and Lake Ajamaru regions of New Guinea^{2,16}. They are also clearly visible in oblique photographs of the Sierra Maestra in Cuba (Fig. 16 of ref. 3), and of the 'Ruined City' of Arnhem Land, Northern Territory, Australia (Fig. XIV-24 of ref. 17) where they isolate numerous pinnacles, towers, and ridges. Less spectacular labyrinths are known in the Tanga region of Tanzania where streets and towers have a maximum relief of 15 m (ref. 18), and in Yunnan, south China, where corridors with ridges and pinnacles up to 30 m high form a landscape that has been described as a "tropical rock forest"¹⁹.

Natural rock labyrinths and associated tower karst are also described in tropical semiarid areas. In the Limestone Ranges of the Fitzroy Basin, Western Australia²⁰, intersecting networks of karst streets up to 6 m wide, 30 m deep, and hundreds of metres long form large areas of 'dissected karst' which include enclosed depressions of angular planform up to 1.5 km long, 180 m wide,

Fig. 2 Aerial photograph of the Nahanni showing labyrinth karst terrain with streets, platea, poljes, and isolated towers.

Fig. 3 A late tower karst stage in the evolution of labyrinth karst in the Nahanni. Insel Tower is approximately 65 m high and rises from a flat alluviated plain.

and 30–45 m deep. These have steep to vertical walls, and flat floors almost entirely mantled by alluvium or residual soil. Jennings and Sweeting²⁰ refer to them as "miniature poljes" but they may well be the semiarid equivalents of karst platea. In addition to the dissected karst are areas of towers, pinnacles, and narrow ridges up to 45 m high which rise from a rock pediplain. The karst of Bom Jesus da Lapa, Brazil, in a limestone hill 2 × 1 km and 200 m high, is similar to the Fitzroy terrain²¹. The hill is crossed by street networks 1–2 m wide and 10–30 m deep which isolate limestone pinnacles, ridges, and towers. Also common are circular solution pits 2–5 m in diameter and 10–30 m deep which appear identical to the dolines that form during the early stage of karstification at Nahanni.

The existence of such similar rock labyrinths in widely distributed carbonate terrains, and of shallower street networks elsewhere^{22–29}, demonstrates that a new karst style—"labyrinth karst"—must be recognised. This style can develop at a variety of scales, with individual depressions ranging from several centimetres to a few hundred metres in depth¹³. During the later stages of evolution a tower karst landscape emerges either directly from karst street networks, or through intermediate platea or platea and polje stages. Variations in morphology between labyrinths are slight and reflect differences in lithology, climate, and in the availability of insoluble residue. The climatic effect is minor. For example, in the Nahanni karst, depression floors and walls are frequently mantled by accumulations of frost-shattered limestone while in the hot semiarid Fitzroy Basin of Australia, where pedimentation processes influence karst evolution, rock debris is uncommon.

In many tropical karstlands two successive stages of erosion can be recognised^{4,5,10}. Cone karst develops until the floors of cockpits extend to local base levels and significant quantities of alluvium are retained. Thresholds between adjacent depressions are submerged, and cones are left standing above broadening alluvial plains. Lateral solutional undercutting may then transform the cones into steep-sided limestone towers. Because true tower karst also forms during labyrinth karst evolution, the tower karst style is polygenetic³. It forms from cone karst when solution is concentrated in a single horizontal plane and from labyrinth karst because solution is concentrated in discrete vertical planes. In the one case tower karst is a conical karst formed under special hydrological, structural and lithological conditions^{6,7,30}, in the other it is entirely a product of particular structural and lithological characteristics.

In the Lake Ajamaru region of New Guinea Pannekoek¹⁶ has identified all stages in a karst cycle of erosion that commences with the formation of small surface valleys aligned along major joints. As water begins to drain underground joints are widened and clefts (karst streets) are opened, isolating angular limestone hills. At this stage the landscape conforms to labyrinth karst. As

Table 1 Suggested temperature and precipitation thresholds for cone and tower karst development

Source	Temperature threshold (°C)	Precipitation threshold (mm)	Area of applicability
Sweeting ⁴		1,840*	Jamaica
Gerstenhauer ⁵	high	1,000	Worldwide
Verstappen ⁶	17–20*	1,500	Worldwide
Balázs ⁷	18	1,200	Worldwide
Sweeting ⁸	18*	1,480*	South China
Williams ⁹	13*	3,250*	New Guinea
Jakucs ¹⁰	17–18	1,000–1,200	Worldwide
Monroe ¹¹		1,300*	Puerto Rico

* Values estimated from statements made by the various authors or from information given by them.

the clefts continue to widen the hills become smaller and lose their angularity so that Kegelkarst topography is produced. Karst on the northern flank of the Sierra Maestra, Cuba (Fig. 16 of ref. 3) seems to fit well into Pannekoek's cycle; residual towers and ridges within a labyrinth are becoming rounded and a landscape resembling oriented cone karst (Ger. gerichteter karst) is emerging. The indication is therefore, that like tower karst, cone karst is polygenetic and that in some areas labyrinth karst may be an early stage in its development.

Once the basic characteristics of cone and tower karst became known in the 1930's and 1940's, examples were reported well outside of modern humid and seasonally humid tropical limits^{31–34}. In almost every case these landscapes were interpreted as fossil, survivals from former periods of tropical climate. For example, Tricart and Da Silva²¹ maintain that the Bom Jesus da Lapa karst was fashioned in a humid Tertiary climate and that it has suffered only minor modification in the much drier conditions that have existed since the late Miocene. A similar interpretation has been put forward for mogotes in the Cracow Upland of Poland³¹, which are identical to the towers of Nahanni, and which are scattered over a similar-sized area (15×5 km). A fossil or palaeoclimatic interpretation of the Nahanni karst is untenable. Evidence such as the presence of abundant erratics from the Canadian Shield indicates that the area was glaciated more than once during the Pleistocene. The present karst landforms are developed from a glacially scoured limestone surface. They post-date the last Laurentide ice to cover the area. The karst therefore seems to have originated in climatic conditions that, on average, were at least as harsh as those of today—that is a mean annual temperature of –4.5°C and a precipitation of only 566 mm. These are well below the minimum conditions supposed necessary for tower karst development (Table 1).

Recent palaeogeographical work in Australia also shows that labyrinth and tower karst can form in cold climatic conditions. In the partly glaciogenic Lower Permian sequence of the Carnarvon Basin, Western Australia is a locally-exhumed karst landscape covering approximately 1,000 km². Karst streets up to 20 m wide, and pinnacle-shaped towers up to 30 m high are developed in calcarenite of the Callytharra Formation. A thick tillite-rich sequence underlies the Callytharra and the karst is overlain by marine sediments containing rare boulder-size erratics. In addition, all Lower Permian faunas from this region indicate cool to temperate conditions (van de Graaff, W. J. E. Hocking, R. M. and Denman, P. D., Geological Survey of Western Australia, personal communication).

Recognition of labyrinth and associated tower karst in climates ranging from humid tropical to dry subarctic suggests that, like doline karst, these styles are not primarily climate or latitude dependent (Table 2). Why then do deep labyrinths and isolated towers develop in some areas and not others, and why are they more common in the tropics? Two local factors seem to have been important in the formation of the Nahanni labyrinths. First, this area was beyond the limits of the Wisconsinan (last) Laurentide ice sheet, and may even have escaped glaciation during the Illinoian period³⁶. It is one of few high-latitude carbonate regions where karst has had time to develop fully, without drastic interruption by flowing ice. Second, although mean soil P_{CO_2} (0.3%), solution intensity ($CaCO_3$ 144 mg l⁻¹), and solute denudation (17.9–27.1 m³ km⁻² yr⁻¹), are much lower than in the tropics, (where the average soil P_{CO_2} at 30 cm depth is 2.0%³⁷, mean water hardness lies between 165 and 180 mg l⁻¹ $CaCO_3$ ^{37,38} and estimated denudation rates include 83 m³ km⁻² yr⁻¹ for Indonesia³⁹, 50–60 m³ km⁻² yr⁻¹ for the Philippines⁴⁰, and 72 m³ km⁻² yr⁻¹ for Jamaica⁴¹) solutational activity is not constant across the area. It seems significant that the deepest solutational landforms are located in a zone that receives large volumes of acid allogenic water from nearby shales, and that elsewhere only shallow karst street networks are encountered. Annual denudation in this zone is two to three times the regional average bringing it close to rates typical of tropical cone and tower regions. At the present rate—approximately 50 m³ km⁻² yr⁻¹—it is estimated that the Nahanni landscape could have formed within the last 200,000 yr, a period that has been available for uninterrupted karst development.

The local factors explain why the Nahanni karst is more highly developed than other subarctic carbonate terrains but not why labyrinth and tower karst predominate, rather than other styles such as doline karst. Many temperate karstlands have longer uninterrupted histories of evolution than the Nahanni, and display greater solute concentrations, runoff and denudation rates than some humid tropical regions³⁷. Yet they lack towers and networks of deep karst streets. Total denudation, therefore, does not determine labyrinth karst development; it seems that structural and lithological properties of the host rock are

Table 2 Areas and climates in which deep labyrinths and late-stage tower karst have been discovered*

Area	Ref.	Approximate latitude	Köppen climate	Temperature (°C)	Precipitation (mm)
Maros, Celebes	14	5°S	Af	26.4	2,850–3,360

* Information given by the authors listed was supplemented from a variety of other sources.
† van de Graaff *et al.*, personal communication (see text).
‡ The position of the Carnarvon area during the early Permian period was estimated from diagrams contained in ref. 35.

primarily responsible. Deep labyrinths are restricted to massive carbonates of low porosity and primary permeability that are crossed by widely spaced, but vertically and horizontally extensive, fractures or fracture zones. There are very few penetrable bedding planes. In many cases the fault and joint networks are results of recent uplift and flexing, which also provided the necessary local relief. Limestones and dolomites suitable for deep labyrinth karst development are comparatively uncommon explaining why this style is not more frequently encountered. Solutional labyrinths of much smaller scale, confined to the uppermost few metres of rock, are more numerous and are termed 'karrenfeld' or 'limestone pavements'^{42,43}.

Although certain broad influences of zonal climate on karst morphology cannot be denied, characteristics of the host carbonate shape the labyrinth karst style. Given an equal distribution of suitable rocks it is to be expected that there will be a greater frequency of this style in the tropics where karst evolution has not been interrupted by glacial events. Tower karst can no longer be regarded as specific to humid tropical climates for it can develop well in cold environments. Some cases where extra-tropical tower karst has been interpreted in terms of tropical palaeoclimatic conditions may require re-evaluation. If the distribution of tower karst is not dependent on climate one of two fundamental pieces of evidence that uphold the morphoclimatic approach to karst geomorphology is no longer valid. In future, more emphasis should be given to structural and lithological properties of the host soluble rock.

Temperature-sensitive mutant of avian erythroblastosis virus suggests a block of differentiation as mechanism of leukaemogenesis

Thomas Graf*, Norbert Ade* & Hartmut Beug*

Max-Planck-Institut für Virusforschung, Biologisch-Medizinische Abteilung, D-7400 Tübingen, FRG

A temperature sensitive mutant has been isolated for the first time from a replication defective acute leukaemia virus, AEV. In vivo, at 41 °C, the mutant shows a reduced leukaemogenic potential. In vitro, in erythroblasts transformed at 35 °C, haemoglobin synthesis can be induced by a shift to 41 °C. This indicates that the continuous expression of a viral gene product is necessary to maintain the undifferentiated state of the virus-transformed leukaemia cells.

THE development of *in vitro* transformation techniques for replication-defective leukaemia viruses in cultures of haematopoietic cells (see ref. 1 for review) introduced a new approach for the study of the mechanism of virus-induced leukaemogenesis. Results obtained mainly with avian erythroblastosis virus (AEV), myeloblastosis virus (AMV) and myelocytomatosis

virus strain MC29 and with the murine Friend and Abelson leukaemia viruses showed that these viruses selectively transform haematopoietic cells of different lineages of differentiation in a highly selective manner¹. Two important questions were raised by these studies. First, is the leukaemic transformation effected by these viruses accompanied by a block of differentiation in their target cells? And second, is a viral gene product necessary to maintain the leukaemic state of the infected cell?

To answer these questions we decided to search for temperature-sensitive mutants of AEV. This virus induces an acute erythroblastosis within 1–2 weeks post-infection if injected intravenously, and slowly developing sarcomas if injected intramuscularly². After infection of bone marrow cells in culture it induces the formation of rapidly proliferating erythroblast foci or colonies^{3–5}. It also induces a transformation of chicken embryo fibroblast cultures^{4,6}. However, AEV does not possess the *src* gene, the gene responsible for transformation of fibroblasts by RSV⁷.

This article reports the isolation of the first temperature-sensitive mutant of AEV and partially answers the questions posed above.

* Present address: Institut für Virusforschung, Deutsches Krebsforschungszentrum, im Neuenheimer Feld 280, D-6900 Heidelberg, FRG.

Fig. 1 Schematic representation of the procedure used to isolate temperature-sensitive mutants of AEV. The AEV used was a RAV-2 pseudotype of AEV-ES4 obtained as described earlier⁴. The virus was treated by mutagen by adding $5 \mu\text{g ml}^{-1}$ 5-azacytidine (Calbiochem) to 45×10^6 erythroblasts producing AEV in 10 ml of growth medium⁴. After 18 h at 37°C the erythroblasts were removed by low-speed centrifugation and the supernatant centrifuged at $70,000g$ for 30 min to pellet the virus. The pellet suspended in 5 ml growth medium was used to infect fresh bone marrow cells which were seeded at 10×10^6 cells per 35-mm dish in methylcellulose-containing medium (ref. 5, and in preparation). After 8–12 days of incubation at 35°C erythroblast colonies were isolated with a drawn out Pasteur pipette, transferred into the wells (15 mm) of a multidose tissue culture tray each containing 0.5 ml growth medium and propagated at 35°C until 10^5 – 10^6 cells were obtained from each colony. The erythroblast colonies were then suspended in 1 ml growth medium, and divided equally into the respective wells of two new trays. One tray was shifted to 41°C , the other was kept at 35°C . After 3 days of incubation at the respective temperatures all cultures were stained with benzidine by the procedure of Orkin *et al.*⁸ to determine the proportion of haemoglobin-positive (B^+) cells. In the scheme, B^+ cells are drawn as closed circles, B^- cells as open circles. In the example shown, clone 3 behaves as expected from an erythroblast clone infected with a temperature-sensitive mutant, that is, B^- at 35°C and B^+ at 41°C ; clones 1 and 2 behave like wild-type-infected cells.

Isolation of erythroblast clones with temperature-sensitive properties

Initial attempts to isolate *ts* mutants of AEV using the fibroblast focus assay⁴ failed to yield the desired mutants (B. Royer-Pokora and T.G., unpublished). With the development of a new transformation assay of bone marrow cells which allows the isolation of clones of transformed cells characterised as immature erythroid cells (erythroblasts) by various differentiation markers and derived from the infection with a single AEV particle (ref. 5, and H.B. *et al.*, in preparation), an alternative approach became possible. The analysis of a large number of individual erythroblast clones obtained with this technique revealed that different clones vary in their haemoglobin expression measured as the proportion of benzidine-positive (B^+) cells. Most of these clones contained less than 10% B^+ cells⁵; this proportion, however, could be greatly increased by the addition of butyric acid⁵. These and other findings not reported here led to the hypothesis that AEV induces a block in differentiation in its haematopoietic target cells. Consequently, if it were possible to inactivate the viral functions in the infected cell, it should be possible to induce a differentiation in the AEV-transformed erythroblasts. Based on this idea a strategy was developed for isolating temperature-sensitive mutants of AEV which is outlined in Fig. 1. Erythroblast colonies were produced by infecting bone marrow cultures with mutagen-treated AEV at 35°C and seeding them into semisolid medium. Cells obtained from individual colonies were propagated at

35°C . Aliquots of these clones were then shifted to 41°C or kept at 35°C and assayed for the proportion of B^+ cells by benzidine staining 3 days later.

From 94 erythroblast clones derived from mutagen-treated virus and assayed in this way, three clones (numbers 3, 34 and 43) were temperature-sensitive for haemoglobin expression, containing more than 70% strongly B^+ cells at 41°C as compared to <10% at 35°C . In contrast, none of 26 colonies derived from untreated AEV showed this type of temperature sensitivity.

AEV from erythroblast clone 34 is temperature sensitive

To determine whether clones 34 and 43 produce virus capable of inducing erythroblast colonies temperature sensitive for haemoglobin expression (clone 3 was lost), cell-free supernatants from both clones were used to infect fresh bone marrow cultures at 35°C . In addition, bone marrow cells were infected with wild type (*wt*) AEV. Between 300 and 1,000 colonies per dish were obtained with the three inocula. Twenty colonies of each type were isolated at random and the 10 fastest growing clones were tested for temperature sensitivity. All of the 10 erythroblast clones derived from clone 34 virus (*ts*34 AEV) could be induced to express haemoglobin, showing an increase from an average of about 13% B^+ cells at 35°C to about 76% at 41°C (Table 1, expt 1). In contrast, with the exception of clone 4, *wt* AEV-infected clones showed essentially identical, relatively low proportions of B^+ cells at both 35 and 41°C (Table 1, expt 1). The virus produced by clone 4 was characterised as *wt* AEV by its inability to induce temperature-sensitive erythroblast colonies (data not shown). The 10 clones induced by virus from clone 43 cells exhibited variable proportions of B^+ cells at 41°C , fluctuating between less than 1% to 59% or greater with an average of 32% (data not shown). It is remarkable that with *ts*34 AEV, in general, those clones which already exhibited relatively high proportions of B^+ cells at 35°C also showed the highest proportions of B^+ cells after shift to 41°C . Photographs of *ts*34 AEV-infected erythroblasts kept at 35°C and at 41°C and stained with benzidine are shown in Fig. 2.

The *ts* lesion is located in the defective, transforming component of *ts*34 AEV

The above results indicate that the temperature sensitivity of haemoglobin expression in erythroblast clones 34 and possibly 43 was due to the infecting AEV/helper virus complex and not to a property inherent to the particular host cells. To determine whether the temperature sensitivity of *ts*34 AEV was due to a mutation in AEV rather than in the helper virus (RAV-2),

Fig. 2 Effect of temperature on the expression of haemoglobin in *ts*34 AEV-infected erythroblasts. Erythroblasts from a single clone were grown at 35°C and aliquots seeded at 35°C (a) and 41°C (b). Three days later the cells were stained with benzidine. The dark cells represent B^+ cells. Aggregation of cells at 41°C usually precedes the appearance of B^+ cells by 1–2 d. Scale bar, 100 μm .

attempts were made to obtain nonproducer erythroblasts containing only the AEV genome. Erythroblast colonies were isolated from bone marrow suspension cultures infected with *ts*34 AEV at low multiplicity. After propagation of the isolated colonies at 35 °C, the supernatants were assayed for reverse transcriptase activity (AEV-transformed nonproducer erythroblasts do not release reverse transcriptase-positive virus particles⁹) and for the production of infectious virus using the bone marrow colony assay to score for nonproducer erythroblast clones. Of eight clones tested, four were found to be nonproducer by both types of assay. All eight *ts*34 AEV-infected erythroblast clones, regardless of whether or not they produced virus, were temperature sensitive for the expression of haemoglobin. This demonstrates that a lesion in AEV and not in the helper virus is responsible for the observed temperature-sensitive expression of haemoglobin in *ts*34 AEV-infected cells. To further substantiate this conclusion, pseudotypes of *ts*34 AEV were produced by superinfection of a *ts*34 AEV nonproducer clone with standard helper viruses. Colonies induced by these pseudotypes were then tested for temperature

Quantitation of haemoglobin expression in *ts*34 AEV-infected erythroblasts

Two types of assay were used to obtain quantitative estimates of haemoglobin expression after shift of *ts*34 AEV- or *wt* AEV-infected erythroblast clones to 41 °C. First, cell extracts were reacted with benzidine and assayed photometrically; and second, a newly developed competition radioimmunoassay for chicken haemoglobin was used. For comparison, before extraction the same clones were subjected to the cytological benzidine assay. The results of these experiments are shown in Table 2. With the benzidine photometric assay a 10- to 15-fold increase was observed in the *ts*-clones 3 days after shift to 41 °C as compared to a 2 to 4-fold increase in the *wt* clones. When the same extracts were tested for haemoglobin by competition radioimmunoassay, a 5 to 7-fold increase was observed in the *ts* clones whereas no or only a slight increase (1.5–2.5-fold) was observed in the *wt* clones.

The smaller increase in haemoglobin levels of the *ts* cells observed by these techniques as compared to the cytological

Pseudotypes of *ts*34 AEV were obtained by inoculating 5 × 10⁵ cells of a clone of *ts*34 AEV nonproducer erythroblasts at 35 °C with about 10⁵ infectious units of RAV-2, SR-RSV-D or AEV (RAV-2). The *wt* AEV (RAV-2 *ts*34) pseudotype was obtained by superinfecting a clone of *wt* AEV nonproducer erythroblasts⁹ with RAV-2 which had been plaque purified¹⁰ from the original stock of *ts*34 AEV. Virus collected 5 days post-infection (p.i.) was used to infect bone marrow cultures at 35 °C. Twenty to 80 colonies were obtained in the cultures infected with the pseudotypes, no colonies were obtained with the supernatant of nonproducer erythroblasts without added helper virus. Colonies were isolated, propagated and tested as described in Fig. 1. In the cultures stained with benzidine a minimum of 250 cells were evaluated. In expt 1, erythroblasts were shifted 17 days p.i. (that is, at about 15–20 population doublings), in expt 2, 24 days p.i. (~22–27 population doublings).

sensitivity. Regardless of whether RAV-2, SR-RSV-D (Table 1, expt 2) or RAV-1 (data not shown) were used as helper virus, all pseudotypes of *ts*34 AEV still induced temperature-sensitive erythroblast colonies. In a similar experiment using *wt* AEV (which contains RAV-2 as helper virus) for superinfection of *ts*34 AEV nonproducer erythroblasts, the resulting virus mixture induced both wild-type (3 out of 7) and temperature-sensitive (4 out of 7) colonies (Table 1, expt 2). This indicates that *ts*34 AEV-infected erythroblasts can be superinfected with *wt* AEV.

An independent line of evidence shows that the original helper virus of *ts*34 AEV is not responsible for the observed temperature-sensitive properties of the latter: a pseudotype consisting of *wt* AEV and the helper virus isolated from the original *ts*34 AEV virus stock failed to cause colonies which were temperature sensitive for the expression of haemoglobin (Table 1, expt 2).

These results suggest that a gene product of AEV blocks the accumulation of haemoglobin, one of the major events during normal erythroid differentiation. In the following, this notion is substantiated by quantitative data on haemoglobin expression and by kinetic studies.

assay probably reflects a threshold effect of the latter method. The expression of haemoglobin in the induced erythroblasts is still far less complete than in fully differentiated cells: depending on technique used, only 2 to 8% of the haemoglobin levels of erythrocytes is expressed in the *ts*34 AEV erythroblasts 3 days after shift. Assuming that the benzidine technique measures the levels of protein-bound and free haem and that the radioimmunoassay detects the levels of haemoglobin as well as free globin, the data in Table 2 suggest that there is a more pronounced or more rapid induction of haem synthesis as compared to globin synthesis in these cells in response to the shift. In addition, our data indicate that in AEV-infected erythroblasts at the 'undifferentiated' stage there is an excess of globin over haem, assuming that equimolar amounts of haem and globin are present in mature erythrocytes.

Kinetics and reversibility of haemoglobin expression

To study the time course of temperature-dependent induction of haemoglobin synthesis, *ts*34 AEV-infected erythroblasts were shifted from 35 to 41 °C and aliquots were stained with ben-

Three clones each of *ts34* AEV- and *wt* AEV-‘transformed’ erythroblasts grown at 35 °C for ~25 population doublings were seeded at 12×10^6 cells in 10 ml growth medium in two 100-mm dishes. One of the dishes was kept at 35 °C, the other was shifted to 41 °C. After 3 days, small aliquots of each clone were separated for protein determination¹² and for staining with benzidine⁸ to reveal the proportion of B⁺ cells and with Trypan blue to reveal the proportion of dead cells. Cell extracts were prepared essentially according to the procedure of Conscience *et al.*¹¹. Of these extracts, 5–50 μ l were used for benzidine staining using the procedure of Crosby *et al.*¹³ and for the competition radioimmunoassay as outlined below. The values shown are the data obtained with the three different clones whereby position 1 always corresponds to clone 1, position 2 to clone 2 and position 3 to clone 3. The values shown were corrected for the proportion of dead cells. Competition radioimmunoassay: chicken haemoglobin was prepared from washed erythrocytes of adult chickens as described by Bruns and Ingram¹⁴. This preparation (~90% pure by SDS-polyacrylamide gel electrophoresis and staining with Coomassie blue) was concentrated to 11 mg ml⁻¹ by ultrafiltration and dialysed against 0.1 M borate buffer pH 8.5. Haemoglobin (30–60 μ g) was then labelled with 0.5–1 mCi [¹²⁵I]Bolton-Hunter reagent (Amersham, 1,700 Ci mmol⁻¹) as described¹⁵. Labelled protein was separated from unreacted iodinated ester and other by-products on a Sephadex G75 superfine (Pharmacia) column (0.5 $\times$ 10 cm) equilibrated with 0.1 M borate buffer pH 8.5 containing 0.25% gelatine. After the addition of 1% Triton X-100 the labelled haemoglobin was stored in aliquots at -70 °C for up to 6 weeks. Radioactivity of the labelled product was between 3 and 6 $\times 10^6$ c.p.m. per μ g protein and of this >90% was in haemoglobin as judged by SDS-polyacrylamide gel electrophoresis and autoradiography. More than 60% of the labelled product was precipitable with an excess of antibody. The reaction mixture for competition radioimmunoassay contained between 50,000 and 60,000 c.p.m. (± 10 –20 ng) of [¹²⁵I]-haemoglobin, 2.5 μ g of rabbit immunoglobulin directed against chicken haemoglobin (Cappel Laboratories) dissolved in 10 μ l RIA-buffer (0.01 M Tris pH 7.0; 0.1 M NaCl and 1% Triton X-100), 5–50 μ l cell extract to be assayed for haemoglobin and RIA-buffer up to a final volume of 400 μ l. After incubation for 2 h at 37 °C and 2 h at 4 °C, 10 μ l of a 10% (v/v) *Staphylococcus aureus* suspension prepared according to Kessler¹⁶ were added and the mixture incubated for another 30 min at 37 °C. The reaction mixture was washed by centrifugation through 500 μ l of 10% sucrose in RIA buffer and the pellet was resuspended in 600 μ l RIA buffer followed by another centrifugation. The radioactivity of the sediment was then determined in a gamma counter. In a typical calibration curve, using a standard haemoglobin preparation, 2 ng of cold haemoglobin resulted in 20% competition; 9 ng in 50% competition and 60 ng in 90% competition.

zidine at daily intervals thereafter. As can be seen from Fig. 3, the proportion of B⁺ cells reached a maximum 3 to 4 days after shift. Thereafter, in most experiments, a slight temporary decline was seen which remains unexplained so far. No significant difference in the kinetics was observed in the absence or presence of helper virus (Fig. 3a). After superinfection of *ts34* AEV nonproducer erythroblasts with *wt* AEV at the time of shift to 41 °C, only a transient expression of haemoglobin within the first 2 days was observed. After 4 to 6 days, haemoglobin expression was again suppressed almost to control levels (Fig. 3a). As shown in Fig. 3b, the increased expression of haemoglobin induced by shift to 41 °C could also be reversed by a subsequent downshift of the *ts34* AEV erythroblasts to 35 °C, exhibiting a similar time course as seen in the upshift experiments.

Leukaemogenicity of *ts34* AEV

If *ts34* AEV does in fact cause a block of differentiation in its target cells at 35 but not at 41 °C, and if this differentiation block is correlated to or even causative of leukaemic transformation, then *ts34* AEV should also exhibit a decreased *in vitro* transforming ability at 41 °C as well as a reduced leukaemogenicity *in vivo* (the body temperature of the chicken exceeds 41 °C).

Assay of *ts34* AEV in bone marrow cells using the methylcellulose colony assay yielded comparable numbers of colonies at 35 and 37 °C (580 and 480) but no colonies at 39 °C. In contrast, however, the number of colonies obtained with *wt* AEV at 39 °C (330) was only slightly lower than at 35 and 37 °C (420 and 370). At 41 °C, no colonies were obtained with either *ts34* AEV or with *wt* AEV, probably reflecting a general inability of normal and transformed chick bone marrow cells to

Fig. 3 Kinetics of haemoglobin expression and effect of superinfection with *wt* AEV of *ts34* AEV-infected erythroblasts. Aliquots were stained with benzidine at different times after shift. In (a), cells from *ts34* AEV nonproducer erythroblasts (clone A6) were shifted from 35 to 41 °C without superinfection (○), after superinfection with RAV-2 (□) or after superinfection with *wt* AEV (RAV-2) at the day of shift (●). In (b), *ts34* AEV cells from a virus-producing erythroblast clone (C2) were shifted from 35 to 41 °C (○) or from 41 to 35 °C (●). As controls, cells were kept at 35 °C (■) or at 41 °C (□). The 41 °C control cells had been shifted from 35 to 41 °C 3 days before the experiment. In all cases, cells were kept at about 1.5×10^6 per ml in growth medium during the experimental period.

Fig. 4 Leukaemogenicity of *ts34* AEV. Three groups of 8-day old chicks were injected i.v. with 0.1 ml of growth medium containing either 1,000 colony-forming units of cell-free *ts34* AEV (RAV-2) (13 chicks); 10 colony-forming units of cell-free *wt* AEV (RAV-2) (9 chicks); or growth medium without virus (9 chicks). All animals were observed for the appearance of erythroblastosis by preparing blood smears at 2–3-day intervals and for death over a period of 3 months. Chicks with *ts34* AEV, circles; with *wt* AEV, squares. Solid symbols, cumulative % death; open symbols, % erythroblastosis.

form colonies in semisolid medium at 41 °C (unpublished observations).

The data in Fig. 4 show that *ts34* AEV is also less leukaemogenic than *wt* AEV. This was not only manifested in the decreased incidence of animals which died of leukaemia (46% as compared to 100% in control animals injected with 100 times fewer colony-forming units of *wt* AEV), but also in a delay of about 1 week in the onset of the disease and in the death of the animals. Interestingly, erythroblastosis spontaneously regressed in three of the mutant-infected chicks. We have never observed such a regression in birds infected with *wt* AEV. Two of the regressors were challenged with about 1,000 colony-forming units of *wt* AEV at 3 months of age and both died of erythroblastosis within 3 weeks post-infection. This indicates that the animals were still fully susceptible to the leukaemia and that the regression observed was probably not due to immunological defense mechanisms.

To determine whether or not the erythroblasts in the *ts34* AEV-infected animals were temperature-sensitive for haemoglobin expression, peripheral blood cells obtained from leukaemic animals were seeded at various concentrations into 15-mm tissue culture wells containing growth medium and incubated at 35 and 41 °C. Six days later foci of growing erythroblasts had developed at both temperatures and these were stained with benzidine *in situ*. The incidence of predominantly B⁺ foci was 2.5% at 35 °C (38 colonies evaluated) and 93% at 41 °C (71 colonies evaluated). In addition, B⁺ foci at 41 °C were somewhat smaller than the foci obtained at 35 °C. Similar results were also obtained with erythroblasts from two further *ts34* AEV-infected chicks, whereas only 7% of the foci at 41 °C (42 colonies evaluated) from a *wt* AEV-infected animals were B⁺.

These results indicate that *ts34* AEV is less leukaemogenic than parental AEV and that the majority of leukaemic erythroblasts from the peripheral blood of mutant-infected chicks still exhibit temperature-sensitive properties.

Discussion

The results presented here show that in erythroblasts transformed by *ts34* AEV the expression of haemoglobin can be induced by raising the temperature from 35 to 41 °C. Together with our finding that the target cell of AEV is an immature erythroid cell (ref. 5 and unpublished results) and the observation that *ts34* AEV showed a decreased leukaemogenicity *in*

vivo, this indicates that AEV induces a block of differentiation in its erythroid target cells and that this block may play a crucial part in virus-induced leukaemogenesis. Preliminary findings showed that *ts34* AEV is still capable of transforming fibroblasts at 41 °C. ARSO, AEV does not possess the *src* gene responsible for sarcoma formation by avian sarcoma viruses⁷. This raises the possibility that virus-induced leukaemogenesis is a process different from fibroblast transformation by avian sarcoma viruses. In this regard it will be interesting to determine whether transformation parameters as defined in the fibroblast system⁶ are also expressed in *ts34* AEV-transformed erythroblasts at 35 °C but not at 41 °C.

Our results are not compatible with the notion that the integration of AEV at a specific site into its host cells is sufficient to induce a leukaemic transformation. Instead, they indicate that an AEV-coded gene product has to be continuously expressed to maintain the block in differentiation and therefore also the leukaemic state of the cell. Whether this gene product is a protein and whether a host function has to be expressed in addition to it remains to be determined. A candidate for an AEV-coded protein responsible for leukaemic transformation is a 75,000 molecular weight polypeptide synthesised in AEV-nonproducer erythroblasts and fibroblasts⁹. This protein consists of part of the *gag* gene of the virus and an unknown portion with a MW of at least 55,000 (ref. 9).

In experiments in which *ts*-mutant-infected erythroblast clones were tested at rather high passages (after ~25 population doublings) only a fraction of the cells from certain clones were inducible and also had an increased tendency to lyse after shift to 41 °C (see Table 1, expt 2 and unpublished observations). Such 'aged' clones infected with *wt* AEV showed also a slight increase in haemoglobin expression after shift to 41 °C (see Table 1, expt 2 and Table 2) and we believe that this reflects a property of the host cells and not of the virus.

The *in vivo* studies with *ts34* AEV clearly show that it is less leukaemogenic than the parental *wt* AEV. Its leakiness is probably due both to its residual ability to block differentiation at 41 °C as suggested by the low levels of haemoglobin expression in some *ts34* AEV-erythroblast clones *in vitro* as well as to the selection of wild-type revertants *in vivo*. A revertant of *ts34* AEV has indeed been isolated from erythroblasts obtained from a *ts34* AEV-infected animal (unpublished results). Interestingly, the well characterised *ts68* mutant of Rous sarcoma virus appears to have an even higher residual oncogenic potential than *ts34* AEV¹⁷.

The observed 'differentiation' of *ts34* AEV-erythroblasts in response to upshift for 3 days was clearly incomplete in that the highest haemoglobin levels expressed in these cells did not exceed 8% of the amount present in mature erythrocytes. This raises the question as to whether the observed effects truly represent a step within normal erythroid differentiation. However, the conditions for induction tested may not yet have been optimal. Thus, in preliminary experiments in which *ts34* AEV erythroblasts were shifted for 8 days to 41 °C, levels of haemoglobin corresponding to about 25% of the amount present in erythrocytes were found. In addition, it might be possible to improve the physiological conditions required for optimal induction and to isolate less leaky mutants of AEV.

Obviously, the exact nature of the AEV-induced block in differentiation needs further clarification such as by studying the influence of metabolic inhibitors on the changes in haemoglobin synthesis and by testing additional parameters of erythroid differentiation. However, it seems already safe to say that chick erythroblasts infected with *ts* mutants of AEV provide a unique new system to study erythroid differentiation *in vitro*, and this can be exploited in a similar way as the induction of differentiation of mouse erythroleukaemia cell lines infected with Friend leukaemia virus by treatment with chemicals¹⁸. In addition, the AEV system has the advantage over the Friend system that possible side effects of chemicals can be avoided and that different diploid clones of 'transformed' erythroblasts can be analysed shortly after infection.

We thank Gabriele Doederlein, Elisabeth Goetz and Sigrid Grieser for technical assistance, Drs J. F. Conscience and W. Schaefer for discussions, and Lynn Graf for help with the manuscript.

A two-step fibrinogen–fibrin transition in blood coagulation

Birger Blombäck, Birgit Hessel, Desmond Hogg & Lisbeth Therkildsen

Department of Blood Coagulation Research, Karolinska Institutet, Stockholm, Sweden and New York Blood Center, New York, New York

The kinetics of the thrombin-catalysed release of fibrinopeptides A and B from human fibrinogen have been investigated and a mechanism correlating the release of fibrinopeptides to fibrin formation is presented. The sequential release of fibrinopeptides results in sequential activation of two sets of polymerisation sites.

WHEN thrombin catalyses the release of fibrinopeptides A and B (FPA and FPB) from mammalian fibrinogen, FPA must appear^{1–5}, followed, after a lag phase, by FPB, for polymerisation to occur. Preferential release of FPB by an enzyme in copperhead snake venom (*Agkistrodon contortrix*) does not result in normal polymer formation unless FPA is also removed^{6,7}. Light-scattering studies^{8,9} have demonstrated two types of initial polymerisation geometry of thrombin-activated fibrinogen. At near-neutral pH the geometry is predominantly end-to-end followed by lateral aggregation⁸. Fibrin formed when FPA is released has a lower mass-to-length ratio than that formed after release of both FPA and FPB¹⁰. Thus, it has been proposed that two sets of polymerisation sites are involved in fibrin formation^{10–12}: one set, A:a, is activated on release of FPA and results in end-to-end polymerisation; the other, B:b, is activated on release of FPB and results in lateral aggregation. Shen *et al.*¹⁶ speculated that the lateral aggregation following release of FPB may be of particular importance for rapid growth of the fibrin fibre. There is direct experimental evidence for at least one set of binding sites, probably the proposed A:a site^{13–15}. Here we report evidence for the existence of the B:b binding sites and that interaction at these sites is responsible for the enhancement of release of FPB observed during fibrin formation¹⁷.

Fibrin formation with and without Ca²⁺

Thrombin cleaves the bonds Aα16Arg–17Gly and Bβ14Arg–15Gly in human fibrinogen. A third bond, Aα19Arg–20Val, is cleaved more slowly¹⁸. Removal of FPA and FPB uncovers Gly as N-terminal residue on both α- and β-chains, but the γ-chain terminus is Tyr. We used N-terminal analysis to estimate the release of FPA and FPB and the cleavage of the third bond using bovine thrombin. These results were corroborated by radioimmunoassay (RIA) for FPA and FPB^{4,5}. Polymerisation was measured by ultraviolet absorption at 450 nm. Control experiments with human thrombin (3,000 NIH units per mg) showed no significant difference. Figure 1a shows the results of N-terminal analysis on thrombin digests of human fibrinogen. The

lower part of this curve corresponds to release of FPA³ which is followed by gel formation, and the upper part is due to the release of FPB³. There was no significant change in the amount of N-terminal valine throughout the digestion.

In similar experiments, FPA and FPB were determined by RIA (Fig. 2a–c). As in previous studies^{2–5}, at all pH values FPA was released first, followed by FPB after a lag phase during which polymerisation began. Rate of release, especially of FPB, was greater at higher pH and the lag phase became shorter. This effect was more evident when lower concentrations of thrombin were used. The gel point occurred when no (pH 6.3) or little (pH 7.4 and 9.0) FPB had been released. At pH 9.0 the gel was transparent; below pH 8.4–8.5 it was opaque, in agreement with the findings of Ferry and Morrisson¹⁹.

Ca²⁺ binds to fibrinogen, shortening the clotting time²⁰, and chelating agents strongly inhibit fibrin formation^{21,22}. We found that the rate of release of the two peptides at different pH values was essentially unaffected by Ca²⁺ (20 mM) and the transition from an opaque to a transparent clot was not observed in the pH range studied.

Release when polymerisation is impaired

Because the release of FPB seemed to be greatly accelerated after the formation of a clot (Figs 1 and 2), we studied its release in systems where polymerisation was impaired. Fibrinogen was digested in 2 M urea and proteolysis was assessed by N-terminal analyses (Fig. 1b). The ratio of Gly:Tyr of 1:1 suggested that only one fibrinopeptide was released when botroxobin fibrin, which is devoid of FPA³, was digested with thrombin (Fig. 1c), and the slow appearance of N-terminal Gly indicated the slow release of FPB. When a non-polymerising N-terminal fragment of fibrinogen (N-DSK)²³ was used as substrate in the absence of urea (Fig. 1d), again only one fibrinopeptide seemed to be released. When N-DSK from botroxobin fibrin was digested, in the absence of urea, the result was similar to that in Fig. 1c.

Digestion of fibrinogen (60 μM) with thrombin in 2 M urea was repeated and the release of FPA and FPB was followed by RIA (Fig. 3a). FPA was released completely but only small amounts of FPB were released and no absorbance increase at 450 nm was observed, indicating that polymerisation had not occurred. When the digest was diluted six times with buffer (pH 7.4) a polymer was formed almost instantaneously and FPB was released rapidly (Fig. 3b). To show that this was not a consequence of changes in fibrinogen or thrombin, caused by urea or on dilution of the urea solution, fibrinogen (60 μM) in 2 M urea was kept for 1 h at 37°C and then diluted with buffer containing thrombin. On dilution, polymerisation occurred and

the sequential release of FPA and FPB was the same as with fibrinogen not pretreated with urea. In a second control experiment, thrombin (0.95 NIH units ml^{-1}) was incubated in 2 M urea for 1 h and then diluted in buffered fibrinogen to give a solution which was 0.33 M in urea and 7 μM in fibrinogen (pH 7.4), and containing 0.16 NIH units of thrombin per ml. Polymerisation occurred in this system and the pattern of release of FPA and FPB was the same as for native fibrinogen at similar thrombin concentrations. Other control experiments were carried out with derivatives of fibrinogen having no capacity to polymerise; botroxobin-treated N-DSK (devoid of FPA but containing FPB) was digested with thrombin in 2 M urea (Fig. 3c). No substantial amounts of FPB were released, but on dilution, it was released slowly (Fig. 3d). FPB was released from polymerising fibrin (Fig. 3b) much faster than from N-DSK in

Fig. 1 Appearance of N-terminal glycine during digestion with thrombin of fibrinogen and derivatives of fibrinogen. Human fibrinogen (95% clottable), fibrinogen and fibrin N-DSK preparations were as described previously^{23,35}. Bovine thrombin, 1,800 NIH units per mg, was purified as described elsewhere³⁵. Botroxobin fibrin was prepared by adding 10 μl of an aqueous solution of botroxobin (from *Botroxobin B marajonesis*, 2,400 BU per mg, Pentapharm, 0.5 mg ml^{-1}) to 6 ml of 1% solution of fibrinogen in 0.15 M NaCl. The solution was incubated at 37 °C for 4 h. The fibrin clot was dissolved in 6 ml 4 M urea and dialysed at +4 °C against 25 mM Tris-HCl, pH 7.2, 2 M in urea and 0.125 M in NaCl. The fibrin solution was diluted to 20 μM with the same buffer and stored at -20 °C in 2 ml portions. Substrates (20 μM) were digested with thrombin at 37 °C in 25 mM Tris-HCl, 0.125 M NaCl, pH 7.2 (where indicated, the medium was 2 M in urea). The procedures used in following the hydrolysis have been described in detail³⁵, 'method A' being used for substrates b and c and 'method B' for substrate d; for substrate a the procedures were modified because fibrin clot formation prevented removal of a representative aliquot of the digest. This problem was circumvented by carrying out the digestion in eight tubes, one tube for each assay time, and thereafter carrying out N-terminal analysis on the contents of each tube according to method A³⁵. a, Fibrinogen, thrombin = 0.18 NIH units ml^{-1} . Arrow indicates the time of formation of a solid gel; b, fibrinogen in 2 M urea, thrombin = 0.82 NIH units ml^{-1} ; c, botroxobin fibrin in 2 M urea, thrombin = 4.0 NIH units ml^{-1} ; d, fibrinogen N-DSK, thrombin = 0.18 NIH units ml^{-1} .

Fig. 2 Thrombin-induced release of FPA and FPB from fibrinogen as determined by radioimmunoassay (RIA) technique. Human fibrinogen (93–100% coagulability) was diluted in Tris-imidazole-HCl buffer⁸ (pH 6.35, 7.4 or 9.0) to give a final solution 17 mM in Tris and imidazole, ionic strength 0.15 and protein concentration 8–10 μM . Fibrinopeptide assay: the fibrinogen solutions were prewarmed at 37 °C. Aliquots of 200 μl were placed in eight siliconised tubes. Bovine thrombin (specific activity 200 NIH units per mg) was added to a final concentration of 0.025 or 0.05 NIH units ml^{-1} and incubated at 37 °C. The digestion was interrupted by adding 0.1–0.2 AT units of hirudin (Pentapharm) at different incubation times. Urea (200 μl of 8 M) was added to dissolve clots formed or, in some cases, the clots were removed before analysis. Radioimmunoassay (RIA) of FPA and FPB was carried out as described elsewhere^{4,5}. Polymerisation: As each of the above samples was taken for RIA determination, a separate prewarmed sample of 1 ml was put into a quartz cuvette and thrombin was immediately added to the same concentration as above. Optical density at 450 nm against time was monitored in an Acta C III spectrophotometer (LKB-Beckman). The transparent type of clot (see Fig. 2c) was not formed in the presence of Ca^{2+} . The time required for formation of a solid gel is indicated by arrows. The latter determinations were carried out in separate tubes. a, pH 6.35; b, pH 7.4; c, pH 9.0. ●, A_{450} ; ×, FPA; ○, FPB.

the same conditions. We believe that the polymer formed on dilution of thrombin-treated fibrinogen in urea solution represents a physiological fibrin structure, because it subsequently cross-linked in the presence of factor XIII_a to give a polyacrylamide gel pattern (Fig. 3, insert) indistinguishable from that produced when fibrinogen, in the absence of urea, was clotted with thrombin in the presence of factor XIII_a and Ca^{2+} .

Another derivative of fibrinogen with impaired gel-forming capacity is obtained by photooxidation²⁴. When photooxidised fibrinogen was exposed to thrombin, FPA only was released rapidly. When this substrate was digested with thrombin in 2 M urea, FPA was released fast and FPB slowly. On dilution of this system, the release of FPB was only slightly increased.

We next investigated congenitally dysfunctional fibrinogen from individuals homozygous and heterozygous for dysfibrinogenemia Detroit, in which fibrin formation is delayed^{25–27}. In this condition FPA is released at an almost normal rate, but the release of FPB is slow. When normal and affected fibrinogen were exposed to thrombin (Fig. 4a–c) the release of FPA was always fast. In homozygous fibrinogen Detroit no polymer formation was observed during FPA release and the initial release of FPB was slow (Fig. 4c). After prolonged incubation, polymerisation occurred and the release of FPB was accelerated concomitantly (Fig. 4c). Heterozygous fibrinogen Detroit (Fig. 4b) gave the same patterns as normal fibrinogen (Fig. 4a), as expected, because the heterozygous fibrinogen contains about 50% 'normal' fibrinogen^{25,27}, providing an initial concentration of 'normal' A α -chain which is almost twice the K_m for thrombin-catalysed cleavage of this domain in fibrinogen²⁸.

To demonstrate the causal link between delayed polymerisation and the release of FPB, fibrinogen Detroit was

digested with botroxobin (Fig. 5b). FPA was released but polymerisation and release of FPB occurred only when thrombin was added (Fig. 5c).

Sequence of events in formation of fibrin

It is thought that one binding domain (A) becomes active after release of FPA and is located in the N-DSK region of fibrinogen¹³⁻¹⁵. This domain interacts with a C-terminal domain (a) located in a plasmin fragment of fibrinogen, fragment D. In

Fig. 3 Thrombin-induced release of FPA and FPB from fibrinogen and N-DSK in urea. *a*, Fibrinogen (see legend to Fig. 2) was reconstituted in 2 M urea to give a solution 0.3 M in NaCl and 60 μ M in protein. This solution (pH $\sim$ 7) was incubated at 37°C with bovine thrombin (200 units per mg) at a concentration of 0.8 NIH units per ml. After various time intervals, aliquots (200 μ l) were taken and thrombin quenched with hirudin (1.0 AT units). RIA was carried out as described in the legend to Fig. 2. *b*, After digestion for 1 h the bulk of the digest was used as follows: 50- μ l aliquots were transferred to a series of siliconised glass tubes. A sixfold dilution was obtained by adding 250 μ l of 17 mM Tris-imidazole-HCl buffer, pH 7.4, containing 24 mM calcium acetate, 2.5 mg factor XIII (Behringwerke) and 1 μ l of Trasylol (Bayer), containing 1,500 KIE per ml, and digests were incubated at 37°C for various times. The reaction was interrupted by adding hirudin (0.5 AT units). Clots (arrow) were formed after dilution and these were removed from one set of experiments for SDS-gel electrophoresis (see inserts). The gel furthest to the left shows the digest, before dilution, contains non-cross-linked α , B β and γ -chains. In the other gels poly α (at the top) and γ - γ dimers (just above α chain) are seen. The clots from another set were dissolved (8 M urea in 0.2 M NaOH) and protein determined at 282 nm using $\epsilon = 5.1 \times 10^{-5}$ (ref. 24). The amount (mg) of protein obtained is shown at the bottom of the SDS gels. FPA and FPB were determined on the clot supernatants using the RIA technique as described in Fig. 2. *c*, N-terminal fragment of fibrinogen (N-DSK)²⁹ was used as substrate. 20 mg of N-DSK in 2 ml of 0.2 M NH_4HCO_3 , pH 7.9, was digested (3 h, 37°C) with 0.2 BU of botroxobin. Botroxobin N-DSK, devoid of FPA, was isolated by gel filtration (Sephadex G-25) in 0.1 M NH_4HCO_3 . Botroxobin N-DSK (60 μ M) in 2 M urea containing 20 mM calcium acetate, was incubated for 60 min at 37°C with thrombin (0.8 NIH units ml^{-1}). FPA and FPB were determined as described in *a*. *d*, Dilution of the botroxobin-N-DSK-solutions was the same as described in *b*. $\times$, FPA; $\circ$, FPB.

Fig. 4 Release of fibrinopeptides and polymerisation in normal and abnormal fibrinogens. Fibrinogens (fraction I-2F) from normal plasma and from two members (heterozygote and homozygote) of a family afflicted with dysfibrinogenemia Detroit were prepared as previously described, omitting the ammonium sulphate precipitation step²⁵. Stock solutions of fibrinogen (60 μ M) in 0.3 M NaCl were prepared. They were diluted with buffers at pH 7.4, containing Tris-imidazole-HCl and calcium acetate to give solutions which were 10 μ M in fibrinogen, 17 mM in Tris-imidazole and 20 mM in calcium acetate. To aliquots (200 μ l) of these solutions 1 μ l of Trasylol (1KIE) was added. Bovine thrombin was added to a concentration of 0.025 NIH units per ml. Incubation was carried out at 37°C for various times and the digestion was interrupted by addition of hirudin (0.1 AT units). Polymerisation was determined as described in the legend to Fig. 2 except that no 'gel time' determination was made. Fibrinopeptides were determined by RIA as described in the legend to Fig. 2. *a*, Normal fibrinogen; *b*, fibrinogen Detroit, heterozygote (S.H.)^{26,27}. *c*, fibrinogen Detroit, homozygote (P.H.)^{26,27}. $\times$, FPA; $\circ$, FPB; $\bullet$, A_{450} .

fibrin formation, an activated A domain of one molecule probably interacts with an A domain of another. Evidence for another set of binding sites comes from our demonstration that the release of FPA from fibrinogen Detroit fails to produce polymerisation, although polymerisation does occur eventually after release of FPB. The A α sites of fibrinogen Detroit are apparently not activated due to the mutation²⁵ A α 19Arg $\rightarrow$ Ser. This mutation, three amino acid residues away from the thrombin-susceptible residue (A α 16Arg) in the A α -chain, would be expected to produce conformational changes in this part of the molecule affecting subsequent interactions²⁹. We propose that the release of FPB activates a polymerisation domain (B) which interacts with another site (b) in a neighbouring molecule. Binding studies¹⁵ with thrombin-activated fibrinogen Detroit coupled to Sepharose have shown that conjugates lacking FPA as well as FPB have no affinity for normal fibrinogen. This puzzling observation could be explained if one polymerisation domain is left intact in fibrinogen Detroit, and is inactivated by the coupling of fibrinogen to Sepharose.

Our results support the suggestion²⁻⁵ that prior release of FPA is essential for the release of FPB in the presence of thrombin. Selective enzymatic removal of FPB from fibrinogen does not produce polymerisation at 37°C unless FPA is also released^{7,8}, demonstrating that the unfolding of the B:b polymerisation sites is linked with the release of FPA. It is interesting that polymer formation greatly accelerates the release of FPB. The experiments with fibrinogen Detroit strongly suggest that this effect is brought about by interactions at the B:b sites. Such interaction could induce a conformational change in a nearby B β -chain favourable to the hydrolysis of the B β 14Arg-15Gly bond by thrombin. The overall consequence of increased FPB release is an acceleration of polymer formation, an effect relevant to any discussion of thrombus formation *in vivo*.

Our results have a bearing on the role of calcium in fibrin formation. It seems that Ca^{2+} , which has only a minor effect on

the activation process itself, shortens the time for subsequent gel formation. This may account for the effect of Ca^{2+} on the opacity of clots. Complete transition from opaque to transparent clots occurs in the absence of Ca^{2+} at pH 8.5. In the presence of Ca^{2+} opaque clots are produced throughout the pH range that has been studied, suggesting that Ca^{2+} influences the ionisation of residues with $pK_s \leq 8.5$. Ca^{2+} ions possibly stabilise a conformation favourable to the formation of opaque clots, and they are known to bind to fibrinogen with high affinity at three binding sites³⁰ and to protect against thermal denaturation³¹.

Light-scattering data⁸ can be interpreted in terms of interacting domains. Those data show that the initial polymerisation geometry at pH 6–7 is predominantly 'end-to-end'⁸. At the lower end of this range, polymerisation is almost exclusively correlated to FPA release and the end-to-end geometry probably results from activation of the A:a binding sites. At pH 9–10, when lateral aggregation is a dominant feature of initial polymerisation geometry⁸, release of FPB is particularly fast and the lag phase is short. Lateral aggregation can therefore be explained by activation of the B:b binding sites after release of FPB. However, the release of FPA is also fast at high pH, indicating that the interaction at the A:a sites is hampered at high pH.

The possible mechanism of fibrin formation *in vivo*

Figure 6 represents the sequence of events in fibrin formation. If the B sites are close to FPB in the dimer of fibrinogen, an interaction involving the B site on one side of the dimer with its corresponding b site can modify the structure of the 'free' B site on the other half-molecule, so that for steric or conformational reasons the B peptide is cleaved faster by thrombin.

Our results are relevant to fibrin formation *in vivo*. The slow initial release of FPB and the presence of antithrombins in blood implies that type I fibrin is the favoured species in blood. Some indications of this were obtained in preliminary experiments with fibrin isolated from clotted whole blood. Blood was drawn into glass bottles containing inhibitors of fibrinolysis (Trasylol, 40 KIE ml^{-1} and ϵ -aminocaproic acid, 2 mg ml^{-1}). The blood

Fig. 6 Schematic representation of sequence of events in fibrin formation. The upper half of the figure shows schematically possible interactions at the sites A:a and B:b. Because of the dimeric nature of fibrinogen each of these sites is present in duplicate, that is, AA₁ and so on. The arrows show that the direction of the initial growth of the polymer is different when the A:a or the B:b sites are exclusively activated. The lower part of the picture summarises the events which occur during formation of the two types of fibrin.

was allowed to clot for 6 h at 37°C and then left overnight at +4°C. The fibrin was isolated by washing extensively with water and buffered glycine solution (pH 6.9) followed by extractions with chloroform-methanol (2:1) and ethanol (30%). The fibrin, highly cross-linked as judged by SDS-gel electrophoresis, was cleaved with CNBr and the N-DSK portion was isolated²³. SDS-gel electrophoresis showed that the purity of the N-DSK isolated from blood fibrin was the same as that of N-DSK prepared from purified fibrinogen. N-terminal analysis of N-DSK from blood fibrin showed a Gly/Tyr ratio of about 1.3:1 compared with the expected 2:1 if both FPA and FPB had been released. When N-DSK from blood fibrin was digested with thrombin (80 NIH units ml^{-1}) the change in N-terminal pattern suggested cleavage of the B β 14Arg-15Gly bond, indicating that FPB was part of the N-DSK structure in this material.

Type II fibrin may therefore form only at sites within blood vessels where the thrombin concentration is extremely high, that is, at the site of a lesion in the vessel wall where adhesion and aggregation of platelets occurs. Near the lesion, thrombin concentration rapidly decreases due to blood flow and interaction with antithrombin, and the fibrin formed is probably mainly type I. However, even a slight activation of the B site with subsequent B:b interaction may considerably change the subsequent time course of fibrin formation due to accelerated FPB release. This may result from disturbances in the composition of blood or its flow properties and may predispose it to the development of occluding thrombi in arteries and veins. It is interesting that type II fibrin seems to be more compact than type I¹⁰ and that the latter is more easily digested by plasmin³². Type I fibrin may then more easily form soluble complexes with fibrinogen which are subsequently attacked rapidly by plasmin^{33,34}.

We thank Mrs Elvy Andersson, Helga Messel, Birgitta Strimme and Sonja Söderman for help, Dr H. Nossel, Columbia University, for the antiserum to human FPB and Drs E. F. Mammen and A. S. Prasad for the Detroit plasma. This work was supported by grants from the Swedish RC (13X-04275) and NIH (HLO7379-12). D.H. received a travelling research fellowship from the Wellcome Trust.

Synthesis of an ovalbumin-like protein by *Escherichia coli* K12 harbouring a recombinant plasmid

Odile Mercereau-Puijalon, André Royal, Brigitte Cami, Axel Garapin, Andrée Krust*, Frank Gannon* & Philippe Kourilsky

Groupe de Biologie Moléculaire du gène, ERA CNRS 201, Unité de Génie Génétique, Institut Pasteur, 28, Rue du Dr. Roux, 75724 Paris Cedex 15

A cloned DNA transcript of ovalbumin mRNA was cut a few nucleotides away from the initiator codon, and fused in phase to the beginning of the Escherichia coli β -galactosidase gene. The hybrid gene has been cloned in E. coli where it produces large amounts of an ovalbumin-like protein.

RECOMBINANT DNA technology now permits the introduction and cloning, in *Escherichia coli* K12, of genes of various origins. However, the expression of foreign genes in this bacterial environment is still poorly documented. Several genes isolated from the lower eukaryotes (yeast, *Neurospora crassa*, *Drosophila*) have been shown to be spontaneously expressed in *E. coli*^{1–6}. There has been no report of genes cloned from the higher eukaryotes that are spontaneously transcribed or translated. Transcription can be efficiently enforced by the integration of gene sequences within a bacterial or a phage gene^{7,8}. It seems that the best way to promote translation into a polypeptide product is by the construction of hybrid genes in which the eukaryotic sequence is fused in phase to a bacterial gene. This approach has been used to construct *E. coli* strains capable of producing the small hormone, somatostatin, in the form of a hybrid protein⁹. The gene coding for the hormone, which is 14 amino acids long, was synthesised chemically, fused to the end of the *E. coli lac Z* gene coding for β -galactosidase and cloned in a multicopy plasmid. The β -galactosidase moiety (about 1,000 amino acids) was elegantly connected to the somatostatin moiety through a methionine residue. As somatostatin contains no methionine, and as the latter is labile in certain conditions, the hormone could be extracted from the hybrid polypeptide by treatment with cyanogen bromide⁹.

Most polypeptides, however, contain methionine residues, so that the above method is not of potential general use unless

other cleavable protein 'linkers' are made available. Many possible applications of genetic engineering, on the other hand, rely on the synthesis of polypeptides larger than somatostatin, coded by gene sequences too long to be chemically synthesised at present. The recent discovery that at least some eukaryotic genes are split^{10–20} makes it unlikely that such genes, isolated from the genome, are easily amenable to expression in *E. coli*. Rather, the most general approach seems to involve (1) enzymatic synthesis of the desired gene sequence from mRNA; (2) fusion of this cDNA sequence to a bacterial gene in such a way that the eukaryotic sequence can be read in the proper phase; (3) cloning in *E. coli*.

We have applied this protocol to the chicken ovalbumin gene sequence and we report here the construction of bacterial strains which synthesise large amounts of an ovalbumin-like protein. This result demonstrates the practicability of the approach and opens broader prospects to genetic engineering methodology.

The ovalbumin system

Ovalbumin is the major egg white protein. It is a polypeptide chain of 386 amino acids, with a single intra-chain disulphide bond, and undergoes a few post-translational modifications such as cleavage of the first methionine residue, N-acetylation, glycosylation and phosphorylation of certain residues. There are several known genetic variants^{21–26}.

Ovalbumin mRNA (ov mRNA) is predominant in the chick oviduct, which facilitates its isolation in relatively pure form. Ov mRNA is 1,859 nucleotides long. Its complete sequence has been determined by McReynolds *et al.*^{26,27}, and consists of a 64-nucleotide long 5' non-coding region, followed by a 1,158-long coding region, and a 637-long 3' non-coding region (Fig. 1).

The ovalbumin gene is split in the chicken genome^{12,16,20}. We have recently isolated, by molecular cloning, the various genomic DNA fragments which code for cytoplasmic ovalbumin mRNA^{16,17}. Analysis of the cloned fragments has revealed the presence of at least six intervening sequences, all located within translated regions of ov mRNA. As the structure of the

Fig. 1 Map of ovalbumin mRNA. Schematic representation of ov mRNA according to McReynolds *et al.*²⁶, showing the translated (T) and non-translated (NT) regions, the AUG start signal (nucleotides 65-67) for protein synthesis, and the position of the *HhaI*, *PstI* and *SstI* sites in the corresponding DNA sequence^{26,31}.

ovalbumin gene was likely to prevent its expression in *E. coli*, we turned our attention towards the DNA transcript of ov mRNA.

Humphries *et al.*²⁸, using a protocol devised for the cloning of globin mRNA transcripts^{29,30}, first isolated a plasmid, pCRI ov2-1, which carries about 1,730 base pairs of DNA transcribed from ov mRNA. Evidence has been presented that a faithful cloned DNA copy is obtained²⁸. As ov mRNA is 1,859 nucleotides long, pCRI ov2-1 does not harbour all the ov mRNA sequence. Restriction mapping, DNA sequencing and electron microscopy analysis^{16,17,28,31}, however, indicate that the missing parts originate from untranslated regions of the mRNA.

As pCRIov2-1 carries all the sequence coding for ovalbumin, we first asked whether the gene is expressed in C600r_m⁺ (pCRIov2-1). Transcription of the ovalbumin sequence from the correct strand could be demonstrated. However, the strain produced no ovalbumin-like protein, as indicated by radioimmunoassays (see below) which were negative, even in conditions where less than one molecule per cell would have been detected (O.M.-P., unpublished). We tentatively concluded that the ovalbumin sequence in pCRIov2-1 has been accidentally fused to an unknown plasmid gene, probably out of the proper reading frame.

Construction of recombinant *lac*-ov plasmids

We then decided to fuse the ovalbumin gene sequence to the beginning of the *E. coli lac Z* gene, which codes for β -galactosidase. Fuller³² has generated a small DNA fragment of 205 base pairs, flanked by two *EcoRI* sites, which carries, in addition

to the L8UV5 *lac* operator promoter region, the information for the first eight amino acids of β -galactosidase. (The L8UV5 mutation makes the system insensitive to catabolite repression.) This fragment was engineered by Charnay *et al.*³³ into a phage, λ cl857plac5 Δ ZL8UV5, the DNA of which has a single *EcoRI* site located after the eighth amino acid of β -galactosidase in the *lac* sequence. We used this DNA to generate by digestion with *EcoRI* and *HindIII* a DNA fragment of 2.85 kilobases which carries the beginning of the *lac* sequence. This fragment was recombined *in vitro* with pBR322 DNA³⁴ digested by the same two enzymes, as outlined in Fig. 2, and cloned in *E. coli*. The resulting plasmid, called pOMP0, was the vector used for further recombination experiments. pOMP0 is about 7.1 kilobases in size. It makes the recipient host cell resistant to ampicillin (but not to tetracycline) and *lac* constitutive (because *lac* repressor is overtitrated by the operator carried by the multicopy plasmid), and has a single *EcoRI* site located near the beginning of the *lac Z* gene (Fig. 2).

Most of the ovalbumin sequence carried by plasmid pCRIov2-1 can be isolated in a restriction fragment of 2,430 base pairs, *Hhaov*, obtained by digestion of plasmid DNA with *HhaI*^{12,28}. The analysis of cloned genomic parts of the ovalbumin gene¹⁷ has demonstrated the existence, near the 5' end, of a site sensitive to *HhaI*, located very close (about 30 base pairs) to an *SstI* site in a region present in pCRIov2-1 (ref. 31). When the nucleotide sequence of this region of ov mRNA established by McReynolds *et al.*²⁶ became available, it seemed that there was no *HhaI* site (GCGC) in the sequence. It occurred to us, however, that 35 nucleotides ahead of the *SstI* site closest to the 5' end (nucleotides 116-120), there was a sequence, GGUGCA (nucleotides 77-82), which could be changed to GGCGCA without modifying the amino acid sequence (GGU and GGC both code for glycine). The assumption could be made that McReynolds *et al.*²⁶ and Humphries *et al.*²⁸ had worked on different genetic variants and that the *HhaI* site which we observed would be located at nucleotides 78-81 of ov mRNA, overlapping two triplets, GGC and GCA, which code for the fifth and sixth amino acids of ovalbumin. Accordingly, the fragment extracted from pCRIov2-1 should be cut at the very beginning of the mRNA sequence coding for amino acids.

Fig. 2 Construction of plasmids pOMP0 and pOMP2. λ cl857plac5L8UV5 Δ Z was constructed by Charnay *et al.*³³ by first inserting the 205-base pair *lac* sequence (described in ref. 32) into the *EcoRI* site located at the end of the *lac Z* gene of a derivative of λ cl857plac5L8UV5. Intramolecular recombination subsequently yielded a phage with only one *EcoRI* site between the end of the *lac Z* gene and the 205-base pair *lac* sequence as shown in a. 500 ng of λ cl857plac5L8UV5 Δ Z DNA (shown as a, where only the region carrying the *lac* sequence is depicted) and 50 ng of pBR322 DNA (shown as b) were digested by *EcoRI* and *HindIII*, and ligated by T4 DNA ligase in a final volume of 15 μ l as usual^{16,35}. Aliquots were used to transform CaCl₂-treated strain 478 (C600 r_m⁺recBC⁻lacy⁻) and transformants were selected on tryptone plates containing ampicillin (20 μ g ml⁻¹) and 5-bromo-4-chloro-indolylgalactoside (X-gal, 40 μ g ml⁻¹), on which strains carrying the recombinant plasmid give blue colonies. Purified pOMP0 was next used to construct recombinant plasmids harbouring the ovalbumin sequence (see legend to Fig. 3). The map of one representative plasmid, pOMP2, was established by restriction analysis using the indicated sites (see Fig. 4). pOMP0 is about 7.1 kilobases long, has single sites for *EcoRI*, *HindIII*, *SstI* and *PstI*. All experiments were carried out with ultrapure hyperhydor water (Institut Pasteur).

Further radioimmunoassays were carried out to quantitate the amount of ovalbumin-like product made in *E. coli*. In Fig. 5, competition by pure, unlabelled ovalbumin (Fig. 5b) is compared to competition by extracts of an *E. coli* strain carrying pOMP2 (Fig. 5a). The competition by the latter is only 80% complete, which suggests that one (or several) antigenic site is missing in the protein manufactured by bacteria. Furthermore, the competition curve may be regarded as being multiphasic. This suggests either that some of the antigenic sites made in *E. coli* are more abundant than others, or that some have a lower affinity than those of native ovalbumin. Because the size of the

ovalbumin-like product is approximately that expected (Fig. 6 and below), we favour the second interpretation. As we noted above, ovalbumin, in the oviduct, undergoes some post-translational modifications which may play an important part in the structure of antigenic determinants. As it is unlikely that such modifications take place in *E. coli*, the ovalbumin-like product (which in any case differs from native ovalbumin by a few amino acids in the N-terminal end) may be, for some of the antigenic sites, a less efficient competitor than ovalbumin. On this assumption, quantitation based on the first part of the multiphasic curve indicates that 2.5×10^6 cells may produce the equivalent of about 15 ng of ovalbumin, that is, about 90,000 molecules of ovalbumin-like protein per cell. If the whole curve was considered as monophasic the estimate would be of 45,000 molecules per cell (5,000–45,000 in a variety of independent experiments, 30,000 on average).

Fig. 4 Restriction analysis of plasmids carrying the ovalbumin sequence. Horizontal agarose (0.5% Sigma type II) gels (25 cm long) were run at 5 V cm^{-1} as in ref. 40. Plasmid DNAs were purified from cleared lysates by phenol extraction and ethanol precipitation, subjected to digestion by *Pst*I endonuclease (Boehringer)^{41,42}, and run in parallel with size markers (lanes 5 and 10: λ cl857Sam7 DNA digested by *Eco*RI and *Bam*HI^{43,44}, lane 11: λ cl857S7 DNA digested by *Eco*RI (ref. 43), lane 12: pBR322 DNA digested by *Hind*III (ref. 34). The size of fragments was estimated on a semilogarithmic plot relating distance to size (in kilobase pairs). Plasmids pOMP1, 2 and 4 (lanes 1, 2 and 3, respectively) show two fragments of estimated size 6.9 and 2.8 kilobases. Plasmids pOMP5, 7, 10 and 11 (lanes 4, 6, 8 and 9, respectively) show two fragments of about 8.65 and 0.7 kilobases. Plasmid pOMP9 (lane 7) does not yield the expected fragments. The total plasmid size (except for pOMP9) can thus be estimated to range over 9.35–9.8 kilobases. The theoretical size is 9.63 kilobases (using estimates of 4.35 kilobases for pBR322; 2.43 kilobases for *Hha*ov; 2.85 kilobases for the λ cl857 *Eco*RI–*Hind*III fragment (as determined by electron microscopy). The respective orientation of the *lac* and ovalbumin sequences which can be deduced from these data was confirmed, in the case of pOMP2, by a variety of other experiments including double digestion by *Pst*I and *Hind*III, which yields three fragments of about 3.45, 3.1 and 2.97 kilobases, and digestion by *Sst*I (data not shown) (see Fig. 2). Lane 13, plasmid pOMP2 digested by *Hind*III (ref. 34).

Fig. 5 Detection of ovalbumin-like protein in bacterial extracts. Ovalbumin (Sigma, 99% pure) ($30 \mu\text{g}$ in $20 \mu\text{l}$) was labelled with 1 mCi of Bolton and Hunter reagent (Amersham; $>1,375 \text{ Ci mmol}^{-1}$), according to the procedure of ref. 45, except that the reaction was stopped after 18 h at 0°C . Radioactive protein was then applied to a Sephadex-G75 column equilibrated with 0.05 M phosphate buffer, $\text{pH } 7.5$, 0.25% gelatin, and eluted with the same buffer. The iodinated product (initial specific activity $\sim 16.5 \mu\text{Ci } \mu\text{g}^{-1}$) was stored at 4°C . Antibodies against ovalbumin were raised in rabbits by injection of 1 mg of ovalbumin (purified by preparative gel electrophoresis) emulsified in Freund's complete adjuvant. A second injection was made 3 weeks later, and bleedings were made 2 weeks after. Antibodies were purified by $(\text{NH}_4)_2\text{SO}_4$ precipitation and chromatography on CM-DEAE cellulose and Biogel P11 columns⁴⁷. Radioimmunoassays were carried out in a final volume of $300 \mu\text{l}$ in PBSA (phosphate buffer 0.1 M , $\text{pH } 7.5$, $\text{NaCl } 0.15 \text{ M}$, bovine serum albumin 5 mg ml^{-1}). To the desired dilution of bacterial extract (or of unlabelled ovalbumin) in PBSA, were added $20 \mu\text{l}$ of mixture containing $15 \mu\text{l}$ of nonspecific rabbit antiserum as a carrier and $10,000 \text{ c.p.m.}$ iodinated ovalbumin. This was followed by addition of $50 \mu\text{l}$ of a dilution of the specific antibodies able to precipitate 50% of the iodinated protein. After an 18-h incubation at 4°C , antibody-bound ovalbumin was separated from free ovalbumin by addition of Na_2SO_4 18% (w/v) final. The precipitate was centrifuged for 5 min at room temperature in a microfuge; supernatants were pipetted and pellets and supernatants counted in a gamma counter. Control experiments with iodinated antibodies demonstrated that precipitation by Na_2SO_4 was essentially complete. Precipitation of iodinated ovalbumin in the absence of specific antibodies did not exceed $5\text{--}8\%$ of input. Strain 1442 (BMH 7156 $\Delta(\text{pro} \text{ lac}) \text{ F}'\text{lac}^{\text{O}^+ \text{Z}} \text{u118}$ was transformed by pOMP2, and grown on glucose minimum plates (to prevent loss of the episome ensuring the overproduction of *lac* repressor). Liquid cultures of 1442 (pOMP2) and C600r $^+$ m $^+$ (pOMP2) in L broth with $5 \mu\text{g ml}^{-1}$ ampicillin were inoculated from plates at about 10^8 cells per ml and grown to about 1.2×10^9 bacteria per ml in the presence or absence of IPTG (5 or 10 mM). In some experiments cultures were directly frozen and sonicated in the presence of protease inhibitor, PTSE⁴⁶ *p*-toluyl-sulphonyl-fluoride, Ega-Chemie, $30 \mu\text{g ml}^{-1}$). In the experiment shown in *a*, bacteria were concentrated 20-fold in PBSA containing PTSE, frozen, sonicated ($2 \times 20 \text{ s}$ in the cold) and diluted serially in the same buffer mixed with a constant amount of extract of the parent strain 1441. Radioimmunoassays were carried out in duplicate. B/B_0 is the ratio between the c.p.m. precipitated in the presence and the absence of bacterial extracts or unlabelled ovalbumin (nonspecifically precipitated c.p.m. being subtracted each time). *a*, Extracts of 1442 (pOMP2) with (▲) and without IPTG (●). The abscissa has been recalculated as μl of nonconcentrated extract ($1 \mu\text{l} = 1.2 \times 10^6$ bacteria). *b*, Standard curve with ovalbumin (Sigma, 99% pure). 50% competition corresponds to 15 ng of pure ovalbumin.

Fig. 6 Size of the ovalbumin-like product in immunoprecipitated bacterial extracts. 5-ml cultures of 1442(pOMP0) (lanes 1 and 2) and 1442(pOMP2) (lanes 3–6) were inoculated at 37 °C in 63B1 glycerol medium supplemented with 5 $\mu\text{g ml}^{-1}$ ampicillin and eventually (lanes 5 and 6) with 1 mM IPTG, grown to an A_{600} of 0.5, labelled with ^{35}S -methionine (Amersham, 50 $\mu\text{Ci ml}^{-1}$, 800 Ci mMol^{-1}) for 30 min and poured over an equal volume of a crushed frozen solution containing 10 mM NaN_3 , 200 $\mu\text{g ml}^{-1}$ chloramphenicol and 30 $\mu\text{g ml}^{-1}$ PTSE. The cells were then centrifuged (5,000 g, 10 min at 4 °C) and frozen at –20 °C. The pellet was resuspended on 0.5 ml of 10 mM Na phosphate buffer, pH 6.8, and sonicated (2 $\times$ 20 s in ice). Immunoprecipitates were prepared as described by Rhoads *et al.*⁴⁷ with minor modifications. To 10⁷ trichloroacetic acid-precipitable c.p.m. were added either 5 μg of unlabelled carrier ovalbumin and 50 μg of bovine serum albumin (BSA) (lanes 3 and 5), or 50 μg of competing unlabelled ovalbumin and 5 μg of BSA (lanes 2, 4 and 6). Samples were adjusted to 1.4% Triton X-100, 1.4% sodium deoxycholate, 10 mM Na phosphate buffer, pH 7.5, and 0.15 M NaCl, to which 20 μl of a nonspecific rabbit serum were added. The mixture (210 μl) was incubated for 30 min at room temperature, layered over 200 μl of 1 M sucrose, 1% Triton X-100, 1% deoxycholate, 10 mM Na phosphate buffer, pH 7.5, and 0.15 M NaCl, and centrifuged (5 min at 4 °C in a microfuge). The upper phase was carefully pipetted and 20 μl of rabbit anti-ovalbumin antibodies, enough to precipitate 7.5 μg of ovalbumin, were added. After 60 min at room temperature, the mixture was layered over sucrose as described above, centrifuged and frozen in liquid N_2 . A 3-mm long tip was cut from the bottom of the tube and the immunoprecipitate was resuspended in 20 μl of 10% glycerol, 2% sodium dodecyl sulphate, 62.5 mM Tris-HCl, pH 6.8, 0.7 M β -mercaptoethanol and bromophenol blue, heated for 2 min at 100 °C and loaded on a sodium dodecyl sulphate polyacrylamide gel. The resolving gel was a 6–15% linear gradient of acrylamide⁴⁸. The electrophoresis was carried out with the apparatus described by Studier⁴⁹ at 4 °C for 12 h at 5 V. After the run, the gel was fixed and stained with Coomassie brilliant blue R-250 (0.2% (w/v) in methanol:water:acetic acid, 50:50:7 v/v), impregnated with diphenylloxazole, dried and fluorographed with flash-activated Fuji RX films according to the standard technique⁵⁰. Exposure was for 24 h at –70 °C. Arrows indicate the position of unlabelled size markers added to each sample: bovine serum albumin (BSA, 68,000 daltons), ovalbumin (OV) and trypsin inhibitor (TI, 21,500 daltons). The immunoprecipitates are contaminated by several bacterial proteins. This is probably due to a weak anti-*E. coli* activity of the rabbit antibodies used. Lanes 1 and 2, 1442(pOMP0); lanes 3 and 4, 1442(pOMP2) without addition of IPTG; lanes 5 and 6, 1442(pOMP2) grown in 1 mM IPTG. In lanes 2, 4 and 6, excess unlabelled ovalbumin was added as a competitor.

We could not clearly demonstrate, in C600 (pOMP2), that the synthesis of the ovalbumin-like product is under the control of the *lac* repressor (which is, at least partially, overtitrated by the operators). Because of this, we introduced pOMP2 into a strain (1442) which overproduces *lac* repressor. Synthesis was then stimulated by the *lac* inducer IPTG about 50-fold (Fig. 5a).

The size of the ovalbumin-like product was estimated as follows: extracts of cells harbouring pOMP2 and labelled *in vivo* with ^{35}S -methionine were precipitated by anti-ovalbumin antibodies, and the dissociated precipitates were loaded on polyacrylamide gels in denaturing conditions as explained in the legend to Fig. 6. The fluorograms in Fig. 6 show a predominant band corresponding to a protein which either co-migrates with or migrates slightly more rapidly than ovalbumin, depending on electrophoresis conditions. In strain 1442 (pOMP2), synthesis of this protein depends on the addition of IPTG. Addition of excess unlabelled ovalbumin in the immunoprecipitation eliminates most of the radioactive band, which indicates that it corresponds to an ovalbumin-like protein. In total labelled extracts not subjected to immunoprecipitation, the band could sometimes be directly observed. In summary, the ovalbumin-like product has a size close to that of ovalbumin.

Synthesis of foreign polypeptides by *E. coli*

We have constructed *E. coli* strains capable of synthesising an ovalbumin-like product. The available evidence indicates that: (1) synthesis of this product is under *lac* repressor control; (2) the product competes efficiently with iodinated ovalbumin in a radioimmunoassay; (3) the size of the product is very similar to that of ovalbumin.

Together, these data strongly suggest that our *E. coli* strains synthesise an ovalbumin-like product, the composition of which is probably very close to that expected, that is, eight amino acids of β -galactosidase and 381 amino acids of ovalbumin (out of the 386 of native ovalbumin). The exact structure of the hybrid protein remains to be investigated.

Bacteria harbouring the recombinant plasmids synthesise an average of 30,000 or 60,000, and up to 45,000 or 90,000 molecules per cell (depending on the interpretation of the radioimmunoassay competition curves). This corresponds to about 0.5–1% of the total protein mass of an *E. coli* cell. These figures are relatively close to the theoretical yield which can be estimated (from the number of β -galactosidase monomers synthesised in cells harbouring a multicopy plasmid with a functional *Z* gene) to be of the order of $1\text{--}2 \times 10^5$ molecules per cell.

The production of high quantities of an ovalbumin-like protein by *E. coli* strains raises several interesting points. First, the strains are perfectly stable and show no tendency to lose the recombinant plasmid. Second, ovalbumin is a secreted protein; in preliminary experiments, we find no trace of ovalbumin-like product in the supernatant of C600 (pOMP2) cultures. Third, the ovalbumin-like protein made by *E. coli* must be relatively stable in the bacterial environment, but no precise measurement has yet been made. Fourth, the codons in ovalbumin mRNA are not randomly distributed²⁶ and their frequency may differ significantly from the frequency of codons in *E. coli*. Some codons (AUC, GUG, CCA, GAC, GAA, GCA) are used more frequently in ovalbumin than in coliphage genes of known sequence^{36,37}, such as MS2 or ΦX174 . The possible deficiency of *E. coli* in the corresponding minor tRNAs does not seem to

interfere much with expression of the ovalbumin gene sequence.

This is, to our knowledge, the first example of synthesis by *E. coli* cells, of a long polypeptide chain from a higher eukaryote. The accuracy of the genetic construction which we made is not perfect, as five amino acids of the natural protein are missing and replaced by a few others from a bacterial protein. There is no theoretical reason, in our opinion, that the site of the junction between the *lac* and the ovalbumin sequences could not be moved down to the ATG initiator codon, leading to the synthesis of an accurate product. This is also the first example of a long polypeptide chain synthesised in good yield from a cloned complementary DNA made from mRNA. As a whole, our experiments demonstrate the feasibility of engineering bacteria for a potentially very large number of uses. Because of its well balanced amino acid content, ovalbumin is often used as a standard for nutritional value, and it is therefore conceivable that the ovalbumin-like product made by bacteria could be used for feeding purposes.

Biohazards associated with the experiments described in this publication have been examined previously by the French National Control Committee. The experiments were carried out accordingly in L1B1 conditions³⁸.

We thank Drs P. Charnay and P. Tiollais for supplying the DNA of phage λ cl857 $\text{plac}5\Delta\text{ZL8UV5}$, Dr J. Rolland for help in the radioimmunoassays including the gift of rabbit antiserum, Mrs A. Hemard for her help in the preparation of the manuscript, Dr J. L. Mandel for providing the *Hha*ov fragment and the *Hha*ov ³²P-labelled probe, Drs J. P. Le Pennec, M. Cochet, and M. Lemeur, P. Farabaugh, M. Hofnung, A. Kornberg and F. Rougeon for the supply of materials, Dr R. Fauve for the use of his gamma-counter, Drs G. Brownlee and A. Fritsch for communication of unpublished results, and Drs C. Leguern and P. Chambon for discussion and information. This work was supported by grants from CNRS (ERA 201, plus an exceptional grant and ATP "Structure du g nome") and from INSERM (CRAT 76.4.310 and 76.4.465). A.R. is a post-doctoral fellow of the National Cancer Institute of Canada.

Nucleotide sequence homology at 12 intron-exon junctions in the chick ovalbumin gene

J. F. Catterall & B. W. O'Malley

A short partial sequence homology is present at all intron-exon junctions, or splice points, in the chick ovalbumin gene; it is probably a signal for a splicing enzyme. The significance of the junction sequences for splicing is discussed. We find no evidence of strong Watson-Crick base pairing between adjacent junctions.

OUR knowledge of the organisation of the ovalbumin gene has advanced rapidly because of the successful cloning of a major part of this gene¹⁻³. Analysis of the clones¹ has shown that the gene is arranged in at least eight separate regions (I-VIII, Fig. 1), which are colinear with the mRNA sequence⁴. But these expressed pieces or exons⁵ are separated by seven sections of

DNA or introns labelled A-G which are absent in the mature mRNA. Given this remarkably complex organisation, how is the mRNA synthesised. Potentially an RNA polymerase could transcribe only the exons leaving the introns alone. This 'jumping polymerase' model⁶ would essentially join up sections I-VIII to give the correct mature mRNA. Alternatively the RNA polymerase could synthesise a copy of the entire gene copying both intron and exon regions. This pre-mRNA could be cut and the exons joined in the correct order, the introns being eliminated. The latter hypothesis seems more likely as there is evidence of a 40S pre-mRNA⁷ containing both exon and intron sequences. This mechanism also occurs for other spliced genes such as those present in adenovirus⁸⁻¹⁰, the β -globin¹¹ and yeast tRNA genes^{12,13}.

The splicing must be a precise process. It has been suggested that two adjacent exons distant in an immunoglobulin λ chain

three of the four bases and three (A/II, IV/D and V/E) have only two bases in common. If the averaging is extended, a less specific sequence T-T-C-A-G-G-T emerges (Table 1). Further analysis of the nucleotide frequencies on the 5' side shows that T residues are preferred and this is particularly noticeable at the 3' end of introns. An impressive example is junction F/VII (Figs 2*b* and 3) where a 'run' of 16 T residues occurs. Thus T residues are common in the intron sequence immediately preceding (5' of) a junction.

Splice points in the mRNA

Figure 4 shows the accurate location of the seven splice points superimposed on the ovalbumin mRNA sequence⁴. This confirms the previous conclusion that the gene is split into eight pieces¹ and that the splice points are all located in the 5' half of the mRNA. The 'limits' of the individual splice points are indicated, the uncertainty arising from the terminal redundancy at the ends of each intron (see above). For splice points (1) and (7) we do not know whether a similar redundancy exists as the complete intron sequence was not included within the 2.4 and 1.8 kilobase DNA fragments studied here.

It would seem likely, however, that splicing should occur at a unique position within the homologous sequence. We can speculate that it occurs at the arrowed position:

as only this position is common to all the redundant sequences (Fig. 3). Kourilsky and Chambon²⁵ have extended this argument and we can formulate the following simple rule. The first cut by the splicing enzyme occurs immediately 5' to a G-T doublet in an intron, and the second cut immediately 3' to an A-G doublet at the other end of the same intron. This rule works without exception for all the known ovalbumin splice points as well as for the immunoglobulin light chain (see Fig. 3).

The separate exon regions vary from the smallest 49±4 residues in length between splice points (2) and (3), to the longest extending 1,030 residues from splice point (7) to the end of the mRNA. Splice (1) occurs in the 5' non-coding region of the mRNA clearly indicating that residues 1-45 of the mRNA have some important function to perform. Possibly they are needed because they form a highly stable hairpin loop near the cap⁴ which is needed for efficient initiation of translation. An analogous splicing of a 'leader' sequence occurs in adenovirus⁸⁻¹⁰ and SV40 DNA^{15,16}.

Significance of the 'consensus' sequence C-A-G-G

Part of the explanation of the consensus sequence is probably the A-G and G-T doublets defining the splice point (see above). However these doublets alone would not give the observed extensive homology. Presumably this homology is part of the recognition sequence for a splicing enzyme but it is not sufficiently conserved, nor long enough to be a unique signal for a splicing enzyme or enzymes. For example, in the 50% (3,400 residues) of the entire ovalbumin gene that we have sequenced (G.G.B. unpublished results), we find 153 positions of which a 3 out of 4 match for this consensus sequence occurs¹⁶. C-A-G-G occurs at 13 of these points and only three of these positions are splice points. Nevertheless the consensus sequence is well conserved among the 12 splice points in the chick ovalbumin gene when compared with the other genes (immunoglobulin, λ and β-globin) in mice, providing strong evidence that it is conserved in evolution. But it does not occur in the spliced tRNA genes in yeast although they may have their own special mechanism as the introns are very short. The basic homology at all the splice points (excepting the tRNA genes) suggests that we are dealing with a single splicing enzyme or at least a small number of closely related enzymes, with a wide specificity amongst different genes. The alternative view that the homology results from the convergent evolution of many different splicing enzymes—for example, one for each splice point—seems unlikely as there is no logical reason why a common sequence

Fig. 3 Sequence at the 12 intron-exon junctions in the ovalbumin gene compared with three other junctions in other genes. For the nomenclature of the ovalbumin junctions see Figs 1 and 4. The terminally redundant sequences (boxed) at each end of an intron were vertically aligned to generate the correct mRNA sequence (Fig. 4) and to maximise homology. Exons are underlined.

should arise. We would expect in that case many different, but unique sequences as occurs for example in the recognition sequence of the many different restriction enzymes¹⁸. We cannot use this homology to definitively predict splice points as the consensus sequence is not characteristic enough. Presumably the additional features, such as the high T content at the 3' end of introns (although a computer analysis shows that this property is not restricted to these regions) and other unknown features allow specific recognition of authentic junctions whilst avoiding other regions.

No obvious base-pairing between adjacent intron-exon junctions

The splicing enzyme needs to do more than recognise specific junction regions. We presume that it must cut and join the correct number of exons in the correct order. Where there are so many (eight) pieces to be joined in a specific order, it would seem extremely wasteful to allow ligation to occur by passive alignment of the correct ends by random diffusion (analogous to the blunt-ended ligation of DNA by the bacteriophage T4 ligase). We favour the hypothesis that a specific mechanism exists to bring the distant exon sequences into close contact. The most obvious hypothesis⁶ is that base-pairing occurs between adjacent junctions, thus generating a large hairpin loop out of the intron. A computer search was made for all secondary structures¹⁹ in Fig. 3 (allowing G-C, A-T and G-T base pairs) that would approximate adjacent junctions. But the free energies (Δ*G*) of the best structures obtained were never less than a few kilocalories²⁰. In every case a more favourable base pairing was possible with known sequences (G.G.B. unpublished) elsewhere in the gene. Despite our inability here to find any positive evidence for a secondary structure model relying on base pairing, we cannot eliminate this mechanism. It is possible that intrinsically quite unstable structures in the pre-mRNA are stabilised by other (tertiary) interactions. For example, there may be long range interactions with other regions in the pre-mRNA or even with other RNA molecules⁶. A more definite analysis of this may be possible when the entire structure of the ovalbumin gene is known. We have also considered models based on the specific affinity of the splicing enzyme(s), or subunits of this, for one another. But such models become attractive only if there are specific and different enzymes for each splice point, as only then could correct splicing be ensured.

Conclusions

The sequence analysis of the 12 intron-exon junctions in the chick ovalbumin gene shows quite clearly that a consensus sequence is present at the splice point. But this homology is only

Fig. 4 The seven splice points in ovalbumin mRNA indicated by symbols ①-⑦. In no case is the splice point precisely known because of terminal redundancy at the ends of the respective intron regions.

partial. This is reminiscent of sequence studies of other important controlling regions such as the promoters in DNAs²¹, or ribosome binding sites in messenger RNA²². Unfortunately the sequence analysis has not elucidated the mechanism by which adjacent exon regions are brought into close contact for splicing. It does seem unlikely that strong Watson-Crick base pairing between adjacent junctions occurs, although we cannot eliminate weak interactions stabilised by other factors. Clearly a direct study of the enzyme or enzymes involved is needed for a more complete understanding of this problem²³.

Y.T. is sponsored by the International Research Fellowship Program, Japan. We thank Dr F. Crick for discussions and Professor Chambon for making his results available before publication.

letters to nature

A larger and more turbulent Universe

THE modern version of the Hubble diagram in which the log of the redshift is plotted against apparent magnitude corrected for redshift and absorption effects of clusters of galaxies, is in principle capable of yielding several cosmologically useful pieces of information. In this letter I report evidence for a significant and substantial departure from the expected redshift for the Virgo cluster of galaxies. A peculiar velocity of $658 \pm 96 \text{ km s}^{-1}$ is derived but because of Virgo's membership in the Local Supercluster, such a value is not unexpected. Thus the turbulence recently observed by Smoot *et al.*¹ for the Galaxy's motion within the Hubble expansion is present elsewhere in the Universe as well. Because the Virgo cluster does not exactly follow the Hubble law, a new value for the Hubble constant equal to $43.4 \pm 2.6 \text{ km s}^{-1} \text{ Mpc}^{-1}$ is found leading to an observable Universe 1/4 to 1/3 again as large as was previously recognised.

When objects with reasonably consistent and sufficiently large luminosities, such as members of clusters of galaxies, are plotted in the Hubble diagram, the mean relation will have the theoretical slope of 1/5 and a dispersion, which because of the nature of a log plot, is greater at low redshifts. The redshift residual of a cluster, if sufficiently greater than the standard deviation about the mean relation, gives the cluster's peculiar radial velocity. If the absolute magnitude of a cluster object is known, its apparent magnitude and the redshift taken from the mean cluster relationship yield the Hubble constant, H_0 . In addition, the curvature of the mean relationship at very large redshifts can give information on galaxy luminosity evolution and the deceleration parameter.

Table 1 Data for clusters of galaxies

Cluster	$c\Delta\lambda/\lambda_0$ (km s^{-1})	Δv (km s^{-1})	$\log cz$	V^*	K_v	A_v
Virgo	$1,144 \pm 68^{6,7}$	361 ± 55	3.1782	10.0^{16}	0.01	0.01
A1367	$6,424 \pm 238^8$	371 ± 57	3.8328	14.32^4	0.04	0.01
A1656	$6,943 \pm 61^9$	315 ± 48	3.8614	14.7^{17}	0.05	0.00
A2199	$9,002 \pm 180^{10-13}$	66 ± 10	3.9577	15.4^{17}	0.06	0.09
A151	$15,749 \pm 309^6$	-328 ± 50	4.1876	16.4^{17}	0.08	0.00
A754	$16,256 \pm 205$	331 ± 51	4.2202	16.78^4	0.08	0.26
A2065	$21,384$	161 ± 25	4.3336	$17.10^{4,17}$	0.10	0.04
	$\pm 298^{6,14*}$					
A2670	$22,491 \pm 300^{15}$	-379 ± 58	4.3441	17.3^{18}	0.11	0.01

The first column gives the cluster identity, the second the redshift in km s^{-1} referred to the Sun, the third the velocity correction of Smoot *et al.* in km s^{-1} , the fourth the log of the relativistically combined redshifts, the fifth the inflection point visual magnitude, V^* , the sixth the K -correction from Schild and Oke⁵, and the seventh the galactic absorption computed from $A_v = 0.19 (\text{csc} |b| - 1)$. The redshift of cluster A754 is an average of three unpublished redshifts which I obtained with the image tube spectrograph and 2.1-m telescope of Kitt Peak National Observatory in February 1975 at a reciprocal dispersion of $111 \text{ \AA mm}^{-1}$. The data represent the combined results of several thousand galaxy magnitude measurements and several hundred galaxy redshift measurements.

* Because of a calibration error in ref. 14, all redshifts were decreased by 121 km s^{-1} .

Although we are far from learning a great deal about evolution and the deceleration parameter from the Hubble diagram, it is now possible to say something about H_0 and the peculiar velocity of at least one of the nearer clusters. This has come about through the use of a reasonably accurate way to gauge relative cluster distances and through a better knowledge of the cluster redshifts. Whereas use of the brightness of the first-ranked cluster galaxy as a distance indicator yields a standard deviation of 0.30 magnitudes about the mean Hubble relation², use of the inflection point in the cluster luminosity function yields a standard deviation almost 3 times smaller^{3,4}. Following the detection of an anisotropy in the cosmic blackbody radiation¹, explained as solar motion of $390 \pm 60 \text{ km s}^{-1}$ relative to the average Hubble expansion in the direction of right ascension and declination, $\alpha = 1 \text{ h}$, $\delta = 6^\circ$ (or galactic longitude and latitude, $l'' = 248^\circ$, $b'' = 56^\circ$), it becomes possible to correct the observed cluster redshifts. For distant clusters this correction is fractionally small but for the nearest ones, proportionally larger changes occur. For the Virgo cluster in particular, the derived peculiar velocity is found to be significantly larger.

Table 1 presents the data for eight clusters. The straight line in Fig. 1 is the best fit with the theoretical slope 1/5 to the 7 most distant clusters and has an intercept on the $\log cz$ axis of 0.9319 ± 0.0091 . Such a fit must be made only to data points with redshifts large enough for the effects of any peculiar velocities to be proportionally small. Because Virgo's corrected redshift is only $1,507 \text{ km s}^{-1}$ and its derived peculiar velocity is almost half this value, the Virgo point must be excluded from the fit. For the most distant cluster (A2670), a peculiar velocity equal to that of Virgo's would be only 3% of the corrected redshift and would result in an additional residual about the mean line of only 0.0137 in $\log cz$ or 0.07 mag.

The standard deviation for the fit of the seven most distant clusters about the straight line is only 0.12 mag. This dispersion is by far the smallest of any of the methods of gauging relative cluster distances. The cosmic dispersion of M_v^* must be even smaller than this value because the precision in determining V^* from the luminosity functions is at present about $\pm 0.05 \text{ mag}$, the galactic absorption is most likely 'spotty', the cluster redshifts have a non-zero mean error, and the clusters other than Virgo may have peculiar radial velocities as well. A trial fit excluding also the second nearest cluster (A1367) reduces the standard deviation to only 0.07 mag.

The Virgo cluster point lies 1.25 mag to the left of the mean relation for the seven clusters but because the residual is greater than 10σ , the Virgo cluster is interpreted as having a peculiar radial velocity of 658 km s^{-1} . The various sources of uncertainty give the standard deviation of this value as 96 km s^{-1} ; thus the Virgo peculiar velocity is certain at almost the 7σ level. An earlier preliminary calculation without the velocity correction gave a peculiar velocity about one half as large¹⁹. This result contradicts the assertions of Sandage and Tammann²⁰ who discount any peculiar velocity for Virgo and argue that the local velocity field is as quiet as it can be²¹.

The Virgo peculiar velocity indicates velocity irregularities on a scale size of about 20 Mpc. Such a condition is not unexpected because the Virgo cluster is a member of the Local Supercluster and must move within it. Following Abell¹⁷, for a supercluster of this size in equilibrium, with a mass of 10^{16} solar masses, and an isotropic velocity field, a radial velocity dispersion of about

850 km s⁻¹ is predicted. The peculiar velocities exhibited by the Galaxy (including its neighbours in the Local Group) and the Virgo cluster may be examples of the motions of clusters within bound superclusters and therefore manifestations of a universal turbulence existing since the early stages of the Universe.

If on the other hand the Local Supercluster is not bound, a cluster with a large peculiar velocity will eventually catch up to clusters with the average Hubble expansion and thus the peculiar velocity will die out with time. In the past the peculiar velocities of clusters would have been even larger. A third possibility, suggested by Rowan-Robinson²², is that entire superclusters are in rapid motion relative to each other. As superclusters are not known to be bound to each other, this motion would also die out with time and would also have been greater in the past. This third situation is not inconsistent with either of the first two—although the first and second are incompatible with each other—and we may in fact be experiencing some combination of motions.

An apparent inconsistency between the solar motion of Smoot *et al.*¹ and that of Rubin *et al.*^{23,24} deserves comment here. From a study of 96 galaxies with 3,500 < *cz* < 6,500 km s⁻¹ Rubin *et al.* derive a solar motion of 600 ± 125 km s⁻¹, but in a direction about 109° away from that of Smoot *et al.* However if Rubin *et al.*'s sample of galaxies has a peculiar velocity of 815 km s⁻¹ relative to the average Hubble flow and in a direction toward α = 12.5 h, δ = 33° (*l*^{II} = 298°, *b*^{II} = 30°) the discrepancy is explained. The picture that is emerging at present therefore is of a Universe that is much more turbulent than previously thought. The quiet velocity field of Sandage and Tammann then is explained by the absence of a correction for the Galaxy's peculiar motion and a less accurate distance indicator (their results yield 34 km s⁻¹ for the Virgo peculiar velocity).

The Hubble constant is derived from the mean cluster predicted redshift of 847 ± 38 km s⁻¹ for Virgo and its distance in Mpc's. Table 2 lists several distances for Virgo taken from the literature. Because the Virgo peculiar velocity was not previously known, the Hubble constants derived here are

Fig. 1 The Hubble diagram for cluster of galaxies based on the inflection point magnitude, *V*^{*}, as a distance indicator. For the best fit to the seven most distant clusters with the theoretical slope of 1/5, the standard deviation is only 0.12 mag. The error bars given the mean errors of the corrected redshifts. Except for the two nearest clusters the mean errors are too small to be shown. The large residual for the Virgo cluster point at the lower left indicates a substantial peculiar velocity for this cluster.

Table 2 Distance of the Virgo cluster and the Hubble constant

Reference for distance	Corrected (<i>m</i> - <i>M</i>) _{AB}	(<i>m</i> - <i>M</i>) _T	<i>D</i> (Mpc)	<i>H</i> ₀ (km s ⁻¹ Mpc ⁻¹)
25, 26	30.9 ± 0.2	30.62 ± 0.2	13.3 ± 1.2	64 ± 7
27, 26	31.3 ± 0.5	31.02 ± 0.5	16.0 ± 3.7	53 ± 13
28, 26	31.9 ± 0.4	31.62 ± 0.4	21.1 ± 3.9	40 ± 8
20	—	31.45 ± 0.09	19.5 ± 0.8	43.4 ± 2.6

Column one gives the reference, two the apparent blue distance modulus corrected as described below, three the true distance modulus, four the distance in Mpc's, and five the Hubble constant in km s⁻¹ Mpc⁻¹. Racine's²⁵ apparent blue modulus has been increased by 0.2 mag to account for a recalibration of his photographic B magnitudes given by Ables *et al.*²⁶. Racine's distance is based on a comparison of globular cluster brightnesses in M87 with those in M31 and the Galaxy. Because the Galaxy is deficient in globular clusters this distance may be too small. Sandage²⁷ and van den Bergh²⁸ compared globular cluster brightnesses in M87 with those in M31 alone. Since their results are based on Racine's measurements however, their moduli have been increased by 0.2 mag also. For these three values the true distance modulus was obtained by subtracting 0.28 mag to account for galactic absorption and *K*-dimming (0.26 and 0.02 mag, respectively). Sandage and Tammann²⁰ give only a true distance modulus based on the brightnesses of Virgo spirals, with the spiral calibration being based on the diameters of HII regions.

significantly smaller than those derived previously. Racine had reported *H*₀ = 79 ± 12, Sandage 75.3 ± 17, van den Bergh 60 ± 12, and Sandage and Tammann a local value of 57 ± 3 and a global value of 55 ± 6 km s⁻¹ Mpc⁻¹. The new values of the Hubble constant in Table 2 are smaller by 19–33%.

On the basis of the least formal error in the distance modulus, the best estimate for the Hubble constant is *H*₀ = 43.4 ± 2.6 km s⁻¹ Mpc⁻¹ which leads to an observable Universe about 1/4 to 1/3 larger than was previously recognised. The corresponding Hubble time (time since the beginning of the Universe if there was no slowing of the expansion) is 22.5 ± 1.4 × 10⁹ yr. As the oldest known stars are about 15 × 10⁹ yr old, there may have been some slowing of the expansion and/or a delay of star formation, possibly due to the turbulence.

Relativistic jets and beams in radio galaxies

RADIO-ASTRONOMICAL observations have recently clarified the link between the components of extended double sources and the primary power supply in the central galactic nucleus. The new data vindicate the general idea¹⁻⁴ that power is continuously supplied by beams; it seems, furthermore, that the beams are collimated in a scale little larger than the central power supply ($\ll 1$ pc), and that the orientation remains fairly steady over the whole lifetime. The giant double source 3C236, 2×10^7 light yr in total extent^{5,6}, has a compact central component aligned with the overall axis⁷; a similar phenomenon is observed in Cygnus A (ref. 8). In NGC6251, a straight jet 200 kpc long⁹ emanates from a 'blowtorch' ≤ 0.1 pc wide in the galactic nucleus¹⁰. There is a radio jet¹¹ in 3C147 reminiscent of the well-known features in M87 and 3C273; and very long baseline interferometry (VLBI) reveals linear structure in several compact extragalactic sources¹². It is argued here that collimation occurs close to a central collapsed object, and that the beams are orientated along its spin axis. Strong-field gravitational effects then stabilise the beams against jitter even if the gas fuelling the source has an inconstant flow pattern. Radio galaxies where the beam axis seems to have gradually drifted or swung, rather than pointing in a constant direction, may belong to a special class that have experienced collisions and recurrent nuclear activity.

The beams squirt from active nuclei with velocities approaching c . The most direct indications of relativistic bulk motions are the 'superluminal' variations¹² in compact sources: the detailed kinematics are still obscure—from a surfeit¹³, not an absence, of acceptable models—but most ideas entail bulk plasma motions at speeds $\sim c$. Indirect evidence for collimated relativistic outflow comes from the polarised optical continuum outbursts in objects such as A0 0235+164 (ref. 14), which pose severe interpretative problems unless the emitting material is directed towards us at speed $\sim c$ (ref. 15). Doppler-favouritism of the approaching beam, when speeds are relativistic, yields a natural explanation for the oneness of jets in, for instance, M87 (refs 16–18).

The central 'engine'—already inferred from source energetics to be highly efficient—seems therefore able to generate plasma whose mean kinetic energy per particle approaches the rest mass energy. Prime candidates for efficient engines are black holes of $\sim 10^8 M_\odot$ accreting from their surroundings: efficiencies can then attain $\sim 10\%$, and the output can persist for the whole $\sim 10^8$ yr lifetime of a giant source like 3C236.

Many variants of this scheme have been theoretically investigated, and almost all can generate the required high mean energy per particle^{19–27}. This is basically because the energy release is concentrated within a few Schwarzschild radii ($r_s \approx 3 \times 10^{13} (M/10^8 M_\odot)$ cm) where the keplerian speeds are $\sim c/2$, as is the sound (or Alfvén) speed in pressure-supported gas. Possible processes near the hole may involve high ion temperatures^{22,27}, relativistic shocks, radiation pressure, magnetic flares^{23,24}, or pulsar-type electromagnetic processes^{25–27}; but all options suggest that a relativistic electron-ion (or e^+e^-) plasma may be the primary product of the gravitational energy released by captured material.

Collimation of this relativistic plasma must demand some asymmetry in the surroundings, probably due to rotation. For instance, if the central power-source is embedded in a rotationally flattened cloud, the plasma will tunnel its way out by excavating nozzles along the rotation axis. This 'twin exhaust' configuration³ (which can create directed beams even if the plasma is generated with an isotropic pressure) could be established on any scale: in particular, there is no reason that the nozzles should not be at $\leq 100 r_s$ if the outflowing plasma originates very near the hole.

The nozzle walls could be confined by hot inwards-spiralling material forming a thick disk or 'donut', centrifugally inhibited from draining into the hole^{29–32}. This confining material would be supported by the pressure of radiation, ions, or magnetic fields. The shape of the nozzles depends on the precise pressure distribution and rotation of the confining cloud, but the walls lie outside the (roughly paraboloidal) surface within which a particle would have so little angular momentum that the hole could swallow it.

Collimation mechanisms influenced by non-newtonian gravitational effects near the hole have some peculiarly interesting consequences, discussed below. Such influences are restricted to length scales much smaller than those for which we have direct radio evidence. The beams, as they propagate outwards, cool in accordance with Bernoulli's equation; they may also cool radiatively, the resulting emission perhaps representing the non-thermal optical continuum from variable galactic nuclei¹⁵. Re-randomisation of bulk kinetic energy occurs in the components of extended double sources where the beams impact on an external medium³. Radiation from the beams themselves (and the superluminal compact sources in particular) indicates some dissipation along the beam due to shock formation, entrainment, or friction. The beam speeds may well remain relativistic out to distances of hundreds of kpc, at least in the stronger sources, otherwise the residual power input into the extended components would be much less than that dissipated by friction along the beam.

The common statement that the beams should be aligned with the associated galaxy's rotation axis (minor axis?) deserves more analysis. One should distinguish the rotation axes of the galaxy, of the infalling gas (which provides the fuel and influences the collimation), and of the black hole itself; anisotropies in the extragalactic environment may complicate the picture still more.

If the relevant gas comes from general stellar mass loss, and pervades (or has been accreted from) the whole galaxy, then its angular momentum vector should coincide with the galaxy's. The same statement holds for primordial gas falling into an elliptical: after one or two orbits its distribution would have become axisymmetric with respect to the galaxy³³. Thus, barring such complications as triaxiality³⁴, the gas should provide a stable long-term symmetry axis. But this gas may not provide an adequate fuelling rate for the most powerful sources³⁵ (unless it accumulates and is then dumped sporadically). This suggests that there may be an extra supply of gas near the nucleus. For instance, Hills^{20,21} invokes a 'debris cloud' of disrupted stars, in which the velocity dispersion is $v_* \approx 10^3$ km s⁻¹. The storage time for gas in this cloud is $t_{\text{store}} \approx (r_s/c)(v_*/c)^{-3}$. The number of stars contributing to the cloud at any instant is then $N \approx t_{\text{store}} \dot{M}/m_*$; the angular momentum vector then jitters, on a timescale $\sim t_{\text{store}}$, by $\sim (N\epsilon)^{-1}$ rad, ϵ being the oblateness of the central star cluster. This could be unacceptably large, suggesting the need for some other process to stabilise the beam orientation.

If the black hole is spinning, the Lense-Thirring 'dragging of inertial frames' influences material sufficiently close to it. An orbit of radius r and period t_{orb} that does not lie in the hole's equatorial plane precesses on a timescale $t_{\text{prec}} \approx t_{\text{orb}}(J/J_{\text{max}})^{-1}(r/r_s)^{3/2}$, J being the hole's angular momentum and J_{max} the maximum angular momentum of a Kerr hole. If the material drifts inwards only slowly (that is, $t_{\text{infall}}(r) \gg t_{\text{orb}}(r)$) then the precession builds up over many orbits. As Bardeen and Petterson³⁶ pointed out, there is then a critical radius r_{BP} at which $t_{\text{prec}} \approx t_{\text{infall}}$. For $r \leq r_{\text{BP}}$, the gas flow is axisymmetric with respect to the hole, irrespective of its original angular momentum. Thus, if the beams are collimated at a radius $\leq r_{\text{BP}}$, their orientation is, in effect, stabilised by the hole; they are then impervious to jitter resulting from short-term (timescale $\ll M/\dot{M}$) fluctuations in the flow pattern of the surrounding gas. If this is the reason for the extraordinary long-term stability of 3C236, the ratio of the size of the source to the dimensions of the nozzle must be $\geq 10^{10}:1$.

Black holes may generally develop from an accumulation of gas with the same provenance as that which later fuels the accretion process. We would then expect alignment of the hole's axis with the angular momentum of the galaxy. But one can envisage circumstances when a galaxy might acquire a misaligned black hole. Suppose, for example, that a galaxy harbouring a central hole—a relic of earlier violent activity—collided or merged with another galaxy³⁷. The new merged galaxy would then be misaligned with its central hole. (The same holds true if the merging galaxies each contained a black hole, and the two holes coalesced.)

What happens if nuclear activity in this merged galaxy is revived by capture of intergalactic gas?³³ Beams collimated at radii $\leq r_{BP}$ will emerge along the hole's rotation axis. But this axis will gradually swing as the accretion proceeds; owing to the Bardeen-Petterson³⁶ effect, each unit mass of infalling material changes the hole's angular momentum by $\sim J_{\max}(r_{BP}/r_s)^{1/2}$. The timescale for the hole to align with its new surroundings is thus $t_{BP} \approx (M/\dot{M})(J/J_{\max})(r_s/r_{BP})^{1/2}$. (This process is more rapid than any forced precession³⁶, unless the black hole acquires a charge which permits electromagnetic torques to act on it³⁸). The value of t_{BP} cannot be estimated precisely, but is of the same general order ($\sim 10^8$ yr) as the overall lifetime of active nuclei.

Reviewers of morphology^{6,39} have noted a class of sources—for example, NGC315, 3C47, 3C192 and perhaps Cygnus A—characterised by reflection symmetry: it seems from the radio contours as though the two symmetrical oppositely-directed beams have gradually swung or drifted over the source lifetime. Perhaps these radio galaxies are systems where a pre-existing central black hole is gradually being torqued into alignment with the angular momentum of newly supplied fuel that has reactivated the nucleus. The gas and plasma dynamics in these sources must be even more complex than in typical doubles. Each beam would be slightly skewed by the transverse drift, the cocoon surrounding it being smeared into a fan shape. (The existence of sharply curved beams in trail sources such as NGC1265 shows that instabilities are not catastrophic even when there is a strong transverse pressure gradient⁴⁰.) This class of sources obviously holds clues to the collimation mechanism and beam dynamics; but they also have added interest if their distinctive morphology is indeed a manifestation of general relativistic effects near a black hole, the scale of the phenomenon amplified 10^{10} -fold by the plasma beams.

I thank Ron Ekers and his colleagues at Groningen for stimulating discussions.

Location of pulsating binary X-ray source 4U1538-52 with the HEAO-1 scanning modulation collimator

THE 529s pulsating^{1,2} X-ray source 4U1538-52 has been found to be a 3.73d eclipsing binary system³. The most accurate orbital elements yet determined⁴ imply that the primary is an early type giant or supergiant star. Independent determination of the primary mass will make it possible to estimate the mass of the (assumed) neutron star secondary. Cowley *et al.*⁵ have surveyed the stars in the Uhuru¹⁹ and Ariel 5⁴ error boxes and called attention to 10 stars consistent with the inferred properties of the primary. A precise (40") position of 4U1538-52 obtained by SAS 3⁶ includes only two of these stars⁵. This letter reports a HEAO-1 position measurement of precision 12" in one dimension which clearly selects one of these two stars (number 12) as the candidate identification.

The HEAO-1 observing programme allowed the scanning modulation collimator (MC) experiment^{7,8} to observe this region from 20 to 28 August 1977. Three constraints limited the data we could use in determining the position: the necessity to avoid the nearby source MX1608-52, which was in a strong transient state at this time^{9,10}; the lack of data during the X-ray eclipses; and the progressive deterioration and failure of one of the four MC2 (120" FWHM modulation collimator) proportional counters during this period. (The one counter was identified and turned off on 29 August 1977, and did not affect MC2 data subsequent to that date.) We therefore obtain only a

Fig. 1 Circle, SAS 3 90% confidence error region. Heavy lines, boundaries of 90% confidence error region determined by the 30 arc s modulation collimator. Numbered stars were observed by Cowley *et al.*⁵. Lettered stars appear in the finding chart given by Apparaio *et al.*⁶.

Fig. 2 Abscissa, mass of the primary in units of the solar mass. Ordinate: $q = M_x/M_p$ on left scale, K = orbital velocity of primary on right scale. Dashed curve: upper limit to allowed parameters if the inclination $i = 90^\circ$. The solid curves are denoted by (X-ray mass function, eclipse half-angle) and enclose the region allowed for $f_M = 12.9 \pm 2.6 M_\odot$ and $\theta_e = 28^\circ \pm 3^\circ$.

single line of position, using 12 orbits of data from MC1 (30" FWHM modulation collimator) on 25 August 1977. The half-width of the error region is 12" (90% confidence), considering counting statistics and aspect solution accuracy. We measure an average flux of $(1.2 \pm 0.2) \times 10^{-10} \text{ erg cm}^{-2} \text{ s}^{-1}$ (2–6 keV), with an additional systematic uncertainty of about 30%.

Figure 1 shows this line of position with the SAS 3 error circle. Stars 10 and 12 are among the candidates noted by Cowley *et al.*⁵. Of all the stars having m_v and $B - V$ consistent with an OB supergiant as required by the X-ray mass function^{3,4}, only star 12 is allowed by the present location. Preliminary optical reports indicate that star 12 is an early-type star¹¹ with He I and H α emission¹², and with radial velocity variations $K \sim 25 \text{ km s}^{-1}$ consistent with the X-ray orbital period, thus proving the identification¹³.

The present system is the fifth example of an X-ray pulsator with a well-defined binary period. The transient 4U0115+63 is the sixth example²⁰, but does not show an X-ray eclipse and therefore a mass solution for the X-ray emitter can not yet be made, pending measurement of ellipsoidal light variations. For the other four neutron stars as a class, it can be established that none has a mass less than 0.6 or greater than $4.0 M_\odot$ (refs 14, 15). For 4U1538–52, the measurements⁴ of the mass function give $f(M) = 13 \pm 2.6$ and measurements of the eclipse semi-duration give $\theta_e = 28^\circ \pm 3^\circ$. We can then express¹⁵ the mass ratio $q = M_x/M_p$ of the X-ray emitting (neutron) star to the primary star as a function of the unknown primary star mass (Fig. 2). This approach differs from that of Davison *et al.*⁴ who assumed a range of 1 to $2 M_\odot$ for the neutron star mass and then derived properties of the primary. Here we make *a priori* assumptions on the mass of the compact star. It is assumed that the primary fills its Roche lobe, and the average radius of the primary as a function of q is taken from Kopal's¹⁷ Table 3-2.

From the duration of the X-ray eclipse we deduce that the primary star radius R_1 is greater than $10 R_\odot$, and from the semi-major axis⁴ $a_x \sin i = 55.2 \pm 3.7$ light-seconds we deduce¹⁷

$R_1 \leq 34 R_\odot$. These limits restrict the star to be either an early type (OB) or a red giant. However, red giants have masses $< 10 M_\odot$, and are directly excluded by the mass function value, as shown in Fig. 2.

For the present candidate, Cowley *et al.*⁵ give a measured $B - V = 2.1$ and apparent $V = 14.1$. Since $(B - V)_0 = -0.3$ for an OB supergiant¹⁶, we have $E_{B-V} = 2.4$ and $A_V = 3.2 E_{B-V} = 7.7$. Such a large reddening in this direction ($l = 327^\circ$, $b = 2.2^\circ$) implies a source located at least 2 kpc distant, behind the Sagittarius–Carina spiral arm. The absolute magnitude is then $M_V \leq -5.4$, and the bolometric luminosity $L_{\text{bol}} \geq 2 \times 10^{38} \text{ erg s}^{-1}$. If we equate $L_{\text{bol}} = \pi R_1^2 \sigma T^4$, we obtain effective temperatures of 1.5 to $3 \times 10^4 \text{ K}$, consistent with B spectral type¹², for the above range of primary star sizes.

From Fig. 2 the allowed range of values of the neutron star mass can be determined for any given primary star mass. For a B0 supergiant, we would expect $M_p \sim 35 M_\odot$ (ref. 22). This would imply $M_x/M_p < 5 \times 10^{-3}$, or $M_x < 0.18 M_\odot$. However, stars in close binary systems are typically less massive than indicated by the spectral type^{15,18,23}, and we could clearly have $M_p = 25$, and any $M_x \leq 10$. Crampton *et al.*²¹ have reported an optical velocity of $33 \pm 7 \text{ km s}^{-1}$. This formally gives $0.08 \leq q \leq 0.13$. From the X-ray mass function and eclipse duration as expressed in Fig. 2, we can derive corresponding limits of $1.2 \leq M_x \leq 3.3$. If the optical velocity were precisely 33 km s^{-1} , uncertainty in the X-ray mass function would allow $1.5 \leq M_x \leq 2.7 M_\odot$.

Determination of the masses of large numbers of neutron stars is of the utmost importance to discriminate among the upper limits to the mass allowed by various models of nuclear structure in the framework of general relativity. For the system 4U1538–52 we still need proof that the compact object is indeed a neutron star, for example, by observation of changes in the pulse period which may be attributed to accretion torques. Further optical study of star 12 is clearly needed to confirm the optical observation of the 3.73-d period, and to measure the optical mass function and ellipsoidal light variations as accurately as possible.

Io may have a bright dawn terminator

NELSON AND HAPKE¹ have shown that occasional observations of post eclipse brightenings (PEB) of the planet Jupiter's satellite Io are very strongly positively correlated with the occurrence of major solar flares within 10° of the solar central meridian (as seen from Jupiter) during the 100 days before the eclipse observation. No eclipses which showed no brightening were preceded by such flares. Io is in the outer part of the jovian radiation belts. Energetic particle fluxes in the Earth's radiation belts at a roughly corresponding location are enhanced for roughly similar times (the 100 days in ref. 1) following the major geomagnetic storms caused by major flares near central meridian^{2,3}. The 100-day time scale is also in reasonable agreement with diffusion times in recent models of the jovian magnetosphere⁴. Considering all this, Nelson and Hapke inferred from their flare correlation that the occurrence of a noticeable PEB effect is due to enhanced fluxes of trapped energetic particles. They suggested that there may be a process similar to thermoluminescence, which converts some fraction of the particle dose received during the eclipse, into visible light which is emitted when the surface is again sunlit, and decays with the characteristic PEB time scale of ~10 min. Although Fanale *et al.*^{5,6} had already suggested that solid state effects in the presence of irradiation by energetic particles might play a part in the PEB phenomenon, the particular correlation with solar flares that Nelson and Hapke found points at once to an energetic particle effect because that is what would be expected to be enhanced by such flares, and at the same time apparently explains the erratic occurrence of PEB on Io and its absence on more distant satellites (because they see much lower fluxes of trapped particles, enhanced or not). In any case, Nelson and Hapke have made a novel yet plausible suggestion which can be tested by laboratory simulation experiments of the solid state process, by more eclipse observations from Earth, and by observations of jovian trapped particles by future flyby and orbiter spacecrafts, and their relation to solar flares. This note suggests another particular test of the thermoluminescence properties of Io which can be made with the unique optical observations which are programmed for the close Voyager I Io flyby in March 1979, and which does not necessarily require a previous suitable flare, as the PEB phenomenon seems to do.

If Io's surface is thermoluminescent with the characteristic PEB time scale of ~10 min, there should be a characteristic bright rim on the sunlit side of Io's dawn terminator. This is essentially because each point on the surface has been 'eclipsed' by Io itself during the night, which is 10 times longer than eclipse, and should accumulate particle dose during the night just as the whole surface would do when eclipsed by the planet. At dawn, it must release all this dose as light on the 10-min time scale. If the time constant in the dark is fairly long compared to the 21-h Io

night, the dawn terminator will be 10 times brighter per unit particle flux than the PEB effect.

To illustrate this, consider a model in which D = stored dose, erg cm^{-2} ; K = light emission rate per stored dose = $K_L \sim 0.1 \text{ min}^{-1}$ in sunlight = K_D ($\ll K_L$) in the dark; e = efficiency of the process; F = particle dose rate, $\text{erg cm}^{-2} \text{ sec}^{-1}$; L = luminosity = KD ; t_e = duration of eclipse. Then, both in sunlight and in the dark,

$$\frac{dD}{dt} = -KD + eF \quad (1)$$

After a few times 10 min in sunlight, the luminosity reaches its equilibrium value $L = eF$. During eclipse or during the night, taking $t = 0$ at immersion

$$L = (K_D/K_L)eF \exp(-K_D t) - eF(1 - \exp(-K_D t)) \quad (2)$$

After eclipse, or at dawn (now taking t as the local Io time since the Sun re-appeared),

$$L = (K_L/K_D - 1)(1 - \exp(-K_D t_e))eF \exp(-K_L t) + eF \quad (3)$$

the spatial shape of the bright dawn terminator in this model is given by replacing t in equation (3) by Φ/Ω , where Φ is longitude from the Io dawn terminator, and Ω is the rotation rate $2\pi/1.79$ days. If $K_D t_e \ll 1$, the luminosity immediately after eclipse or dawn, is

$$L_B \sim (1 + K_L t_e)eF \quad (4)$$

This is about 15 eF for jovian eclipses and about 130 eF for the bright dawn terminator effect. The light curve predicted by equations (2) and (3) with $K_D t_e \ll 0.1$ is shown in Fig. 1.

There are two areas where the idea of bright dawn terminator suggested here is related to the Nelson-Hapke model of PEB. (1) The size and shape of the bright region near the dawn terminator depends in detail on the parameters in equation (3). If one supposes that thermoluminescence occurs on Io without specifying the rate constants, a distinct small bright area is not generally predicted. It occurs in our model because we use the PEB decay rate of 0.1 min^{-1} for K_L . (2) The actual luminosity of the bright area near the terminator is predicted by equation (4) to be 130/15 times the brightness of PEB at the same particle dose rate. Turning this around, one concludes that if it is fairly sure that the dose rate enhancements induced at Io by solar flares are not much more than a factor of 130/15, the bright dawn terminator should be at least as bright as the PEB.

The important point about the predicted bright dawn terminator is that it would provide an opportunity to observe the colour and temperature dependence of the suggested Io thermoluminescence whenever the flyby spacecraft arrive, since it does not require an eclipse and may not require enhanced particle fluxes.

The bright dawn terminator should extend about 10 min of the Io day from the geometrical terminator in our model. This is only $(10 \text{ min}/42 \text{ h}) \times 360^\circ = 1.4^\circ$ of Io longitude into the sunlit side. It is not surprising this has never been observed from Earth, as it is small and highly foreshortened.

On 5 March 1979, Voyager I will observe Io optically from altitudes of 22,000 to 65,000 km, including large areas around both the dawn and dusk terminators within about 60° of Io's south pole, in six spectral regions defined by colour filters from violet to yellow (E. C. Stone, personal communication). The spatial resolution of these pictures should be adequate to reveal the bright dawn terminator effect if it exists and is bright enough.

The shape of the predicted bright area near Io's dawn terminator is actually determined by how K_L (see, for example, ref. 1) really changes locally as the Sun rises. Thus, the shape of the bright regions can be used to determine the variation of K_L and will be an important constraint on the thermoluminescence model. The eclipse light-curves are not sensitive to this effect. For example, if K_L varies after dawn like $K_L \sin \Omega t$ where Ω is the rotation frequency of Io and t the time since dawn, the brightness of the terminator is reduced to about $eF (K_L t_e)^{1/2}$ and

Fig. 1 Possible light curve of 'thermoluminescent' light from Io with parameters given in the text. If the thermoluminescent emission rate is proportional to the solar illumination, the bright dawn terminator effect is moved to the right and its intensity reduced.

the position of maximum intensity is pushed away from the geometrical terminator, to about $(\pi K_L t_0)^{1/2}$ radians, or 9° of longitude into the dayside of the terminator. Thus it is quite important that we have adequate resolution in λ_0 longitude to determine the position of the maximum brightness, and other details of the spatial dependence of this effect, so that the intensity of the effect may be properly interpreted. Particle flux levels measured at the same time will determine ϵ . The colour of the excess light should help to define the 'thermoluminescent' system. Comparison of the planned observations of the terminator 1 h apart (E. C. Stone, personal communication) will determine some spatial variations in ϵ and possibly other aspects of this process which might well occur due to uneven bombardment of λ_0 by the corotating energetic particle fluxes in the jovian magnetosphere.

I thank John Caldwell and Ian Axford for discussions. This work was supported in part by NASA grant NGR-33-015-180.

Millisecond
microwave spikes in a solar flare

THE shortest-lived structures in microwave solar flares known until now last ~ 1 s. Recently (11 April 1978) we observed a microwave outburst at 2.65 GHz (starting at 13.41 UT) showing a strong and extremely fast fluctuating burst component. Many spikes appeared to have half-power durations smaller than the 20-ms resolution of the instrument used. These are about two orders of magnitude shorter-lived than events reported from previous microwave observations. They are only rivalled by fine structure in some decimetric type IV bursts between 0.4 and 1.4 GHz (ref. 1).

The occurrence of microwave flares with millisecond fine structure is probably not very rare as we observed a second example on 28 April 1978 around 13.50 UT. Our resolution at

Fig. 2 Flux density of both left (LCP) and right (RCP) circularly polarised components of the most variable part of the event. The fine structure is not resolved. The indicated fragment (*) of about 2 s is expanded in Fig. 3. Note that this is not one of the most intense peaks but rather a typical one.

that time was limited to 100 ms, which turned out to be insufficient. The importance of this last flare in H_α was rather high, 4B, but that of the flare at 11 April had the more common rating 2B.

Our observations were made with a double sideband receiver sensitive to two bands of 12 MHz separated by 60 MHz. The receiver measures both left and right circularly polarised radiation (LCP and RCP), with an effective time constant of 10 ms. The outputs are recorded on stripchart recorders, allowing a maximum resolution of 100 ms, and, for full resolution, on magnetic tape with a sampling interval of 10 ms.

The microwave flare consisted of a large number of successive bursts (see Fig. 1). Some of these showed millisecond structure. The general behaviour on 2,650 MHz (Dwingeloo) corresponds very well with that on 2,800 MHz (Ottawa), but a sharp high frequency cut off is quite clear during the whole event. For the smooth component we found a fall of 3-5 dB over only 150 MHz. The fluctuating component is less easy to compare as the Ottawa time constant is much larger than the duration of the spikes. Comparison of this component after averaging over 0.5 s in both recordings yields a fall of 5-7 dB. The three major bursts (14.05, 14.20 and 14.40 UT) showed at 2,650 MHz a weakly L

Fig. 1 Reconstruction for H_α flare, 2B, N19W54, of the total power recording of 2,650 MHz flux observed at Dwingeloo (2) compared with that of 2,800 MHz flux observed at A.R.O. (1) (courtesy M. B. Bell at A.R.O., Ottawa). Data reconstructed from a logarithmic channel. The period of strong variability coincides for both frequencies. This period is shown expanded in Fig. 2.

polarised continuum, the first one without any spikes, the second one with a very large number of 100% L.C.P. spikes and the last one with sporadic, hardly (if at all) polarised, spikes (one might consider the weakly polarised continuum to be composed of spatially different L and R sources, but then these would have to show quite precisely the same temporal development; besides the occurrence of weakly polarised spikes sustains the concept of a weakly polarised source).

The spikes around 14.21 UT were analysed in detail. All were 100% L.C.P. Flux densities of up to $6 \times 10^{-19} \text{ W m}^{-2} \text{ Hz}^{-1}$ were observed for the spikes for nearly all durations (Fig. 3). The occurrence of these spikes starts along with the rise of the continuum, but ends rather abruptly (Fig. 2) long before the continuum died out.

The half-power durations of the spikes were almost all (95%) below 40 ms, while the abundance increased with decreasing duration (Fig. 4). This implies that many spikes were not resolved. The intervals between successive spikes were also rather short: 72% were below 50 ms and again their abundance was larger the shorter their value. There were no conspicuous periodicities but too many values were rather close to the sampling interval.

An important consequence is that the particle acceleration mechanism must be effective on the time scale of milliseconds, which is 2 or 3 orders of magnitude shorter than hitherto envisaged in most models^{2,3}. However, recently a pulsed

Fig. 3 Full resolution recording of a typical fragment of the fine structure. The intervals between measured flux values are 10 ms. Date, 11 April 1978.

acceleration process has been proposed⁴ where the time scales of the acceleration is the local collision time. Indeed the collision damping rate for plausible source conditions (kinetic temperature 10^7 K , particle density 10^{11} cm^{-3}) is a few milliseconds. Hence we assume the spike durations to be determined by the excitation periods. We can now estimate the source dimensions by assuming a spatial growth rate between the Alfvén speed and c . A plausible Alfvén speed would be $\approx 3,000 \text{ km s}^{-1}$ (field strength $\approx 300 \text{ G}$). A spike lasting 10 ms would then have a source width between 30 and 3,000 km. As an m.h.d. instability is the most likely generating process^{2,3}, dimensions of the order of tens of kilometres are a realistic estimate. Such values are considerably shorter than observed for microwave sources ($\approx 8,000 \text{ km}$)³ and H_α kernels (3,000–6,000 km), but have been hinted at in theoretical models^{2,3}.

The flux densities of the spikes, together with the source size estimates given above, lead to a lower limit of the brightness temperatures of $\sim 10^{15} \text{ K}$. Obviously a coherent radiation mechanism is necessary to account for such values. It is interesting to note that the completely polarised spikes can be explained as plasma radiation at the fundamental frequency, arising from induced scattering of Langmuir waves present in the pulsed acceleration model⁴, while the continuum burst can be explained as weakly polarised self-absorbed gyro-synch-

Fig. 4 Peak flux values of spikes plotted against their half-power durations. Curves of constant brightness temperature are drawn taking the Alfvén speed times the duration as typical dimension of the spike sources. Durations below 10 ms are cut off by the time constant of the receiver.

rotron radiation from the heated and accelerated particles all over the flare region. Observation of microwave spikes should provide direct evidence of the elementary flare processes.

First mass analysis of stratospheric negative ions

ATMOSPHERIC negative ions have been identified previously by *in situ* mass spectrometric measurements only at altitudes above $\sim 70 \text{ km}$, which was the operational height limit of the rocket-borne instruments used^{1,2}. These measurements revealed the presence of atomic, molecular and cluster ions mostly having masses between 35 and 152 AMU. Here we report preliminary results of the first mass spectrometric measurements of stratospheric negative ions. Only observed mass numbers will be presented. A detailed analysis of the ion abundances, will be published elsewhere.

Three flights of a balloon-borne mass spectrometer probe were conducted during daytime over southwestern France (flight 1: 2 September 1977; flight 2: 26 September 1977; flight 3: 10 November 1977). Peak altitudes of 33.5, 35, and 37 km were reached. The instrument, developed and built at the Max-Planck-Institut für Kernphysik, has been previously described along with the circumstances of the flight measurements and the preliminary positive ion composition data obtained simultaneously³ and will not be reported here. Note, however, that the mass resolution setting of the instrument was lower for negative ions (~ 22) than for positive ions (~ 50) in favour of an increased transmission of the mass filter. Thereby a signal-to-noise ratio for negative ions comparable to that for positive ions should be achieved considering the higher dark count rate of the ion detection system in the negative ion measurement associated with the higher voltage applied to the channeltron.

Most negative ion data were obtained at the peak altitudes and only these will be reported here. As far as the major masses are concerned, the data obtained in the different flights agree with each other. The uncertainty of the mass identification up to ± 3 AMU is due to the limited definition of the flanks of the mass peaks. Laboratory and in-flight-calibrations of the mass scale were performed³. The width of a mass peak is typically about 15 AMU which implies that small mass peaks may easily become covered by large ones and thus may not be detectable.

The major ion masses (fractional abundance $> 1\%$) given in Table 1 cover the range from 125 to 295 AMU. When compared to the masses of the major positive ions observed in the same flights ranging from 55 to 140 ± 2 AMU (ref. 3), they are larger and are also greater than the negative ion masses observed above 70 km which were mentioned before.

Table 1 Mass numbers and tentative identifications of major negative ions observed at 33–37 km altitude

Mass	Tentative identification
125 ± 2	$\text{NO}_3^-\text{HNO}_3$
161 ± 2	R^-HNO_3 $\text{NO}_3^-\text{HNO}_3\text{HCl}$
188 ± 2	$\text{NO}_3^-(\text{HNO}_3)_2$
197 ± 3	R^-HR
224 ± 3	$\text{R}^-(\text{HNO}_3)_2$ $\text{NO}_3^-(\text{HNO}_3)_2\text{HCl}$
253 ± 3	$\text{NO}_3^-(\text{HNO}_3)_3$
260 ± 3	R^-HRHNO_3
289 ± 3	$\text{R}^-(\text{HNO}_3)_3$ $\text{NO}_3^-(\text{HNO}_3)_3\text{HCl}$
295 ± 3	$\text{R}^-(\text{HR})_2$

For identification of R see text.

An identification of the chemical nature of the observed negative ions is difficult at present mainly because of the limited mass accuracy, the lack of rate constants of relevant ion molecule reactions and the poor knowledge of stratospheric trace gases. Nevertheless, some general conclusions concerning the nature of the observed ions may be drawn.

The high mass numbers probably indicate cluster ions consisting of a core ion and attached ligand molecules. An upper mass limit of the least massive core ion is defined by the smallest major ion mass (125) observed. This is consistent with a core ion NO_3^- (62 AMU) being considered as the favoured core ion of stratospheric negative cluster ions because of the large electron affinity of NO_3^- (ref. 4). If the core ion is actually NO_3^- , mass 125 may be identified as $\text{NO}_3^-\text{HNO}_3$. The average mass of the building blocks of the cluster ions (core ion and ligand molecules) may be estimated by considering the following argument: the association order (number of ligand molecules attached to the core ion) of the negative cluster ions should be less than that of the $\text{H}_3\text{O}^+(\text{H}_2\text{O})_n$ ions measured simultaneously. This has to be expected as the atmospheric concentration of the ligand molecules is probably lower than that of water and since the

bond energies of negative cluster ions inferred from laboratory measurements is generally lower than that of the $\text{H}_3\text{O}^+(\text{H}_2\text{O})_n$ ions of the same association order (see ref. 5). A lower limit for the mass of the building blocks of about 74 ± 3 AMU may be estimated by considering a maximum association order of 3, the same as that of the observed $\text{H}_3\text{O}^+(\text{H}_2\text{O})_n$ ions and a maximum mass of the observed major negative ions of 295 ± 3 AMU. A large average mass of the ligand molecules is also inferred from the large mass difference of adjacent mass peaks. This rules out an identification of the observed negative ions as hydrates which were previously considered to dominate in the stratosphere⁶.

Our conclusion is supported by laboratory measurements of gas phase hydration equilibria of negative ions (see refs 7, 8; Fehsenfeld, personal communication; ref. 8) inferring that negative hydrates should contain only one or two water molecules at water vapour pressures and temperatures prevailing at 34–37 km altitude. Most likely, the ligand molecules are stratospheric trace gases which are much less abundant and which are stronger bound to negative ions than water.

The ligand molecules should have large gas phase acidities as laboratory studies indicate that the bond energy of a molecule to a negative ion increases with the gas phase acidity of the molecules⁹. Favoured candidates therefore seem to be, HI , HNO_3 , HBr , HCl , and H_2SO_4 . Cluster ions of the type $\text{NO}_3^-(\text{HNO}_3)_n$ which were previously proposed to exist in the stratosphere⁴ would be consistent with the observed masses 125 ± 2 ($\text{NO}_3^-\text{HNO}_3$), 188 ± 2 ($\text{NO}_3^-(\text{HNO}_3)_2$) and 252 ± 3 ($\text{NO}_3^-(\text{HNO}_3)_3$). The observed masses 161 ± 3 , 197 ± 3 , 224 ± 3 , 260 ± 3 , 289 ± 3 and 295 ± 3 seem to fit a pattern $\text{R}^-(\text{HR})_n(\text{HNO}_3)_n$ with HR having a mass of 98 ± 2 AMU and with $m+n \leq 3$ (Table 1). A tentative candidate for HR seems to be H_2SO_4 . Another possibility might be HClO_4 but this is unlikely to be sufficiently abundant in the upper stratosphere.

The identification of the observed ions deserves further investigation involving the determination of relative ion abundances, *in situ* measurements with higher mass resolution and laboratory studies of relevant ion reactions. Such measurements should also provide a base for an analytical application of stratospheric ion composition measurements in terms of a determination of the concentrations of certain neutral trace gases involved in stratospheric ion molecule reactions. If the observed ions would actually contain HNO_3 , H_2SO_4 and HCl , it should be possible to derive the concentrations of these gases from the ion composition. Thus, ion composition measurements may become a powerful analytical tool, which allows the detection of very small gas concentrations^{3,4,10}.

Effect of the reaction $\text{HO}_2 + \text{O}_3 \rightarrow \text{OH} + 2\text{O}_2$ on stratospheric ozone

THE recent measurements¹⁻³ of large values (8.1 ± 1.5 and $8.2 \pm 2.7 \times 10^{-12} \text{ cm}^3 \text{ s}^{-1}$) of the rate coefficient for the reaction

have led to some important revisions in our understanding of stratospheric photochemistry⁴. In particular, the predicted ozone perturbations due to the injection of nitrogen oxides by supersonic transport aircraft have become net ozone gains instead of losses⁵, while the predicted ozone depletion due to ozone-active chlorine from chlorofluoromethanes has almost doubled⁴. An unfavourable result of the adoption of the larger value of the rate coefficient for reaction (1) has been the prediction of excessive amounts of stratospheric ozone (10–20% more than the measured concentrations) both in terms of the total column abundance and the concentration profile at altitudes below 40 km. Attempts to remedy this discrepancy between theory and observation by altering the simulated lower stratosphere transport and by increasing the assumed amount of ozone-active chlorine were not successful. It is the purpose of this letter, however, to show that another recent measurement by Zahniser and Howard⁶ of the rate coefficient, k_2 , for the reaction

largely resolves these problems of excessive stratospheric ozone in models. Zahniser and Howard have reported the first direct measurement of the reaction between HO_2 and ozone (reaction 2). Their temperature-dependent rate coefficient is

$$k_2 = (1.4 \pm 0.4) \times 10^{-14} \exp [-(580 \pm 100)/T] \text{ cm}^3 \text{ s}^{-1}$$

which at stratospheric temperatures is 4 to 5 times larger than the value recommended in the report of the NASA Chlorofluoromethane (CFM) Workshop⁴, that is, $7.3 \times 10^{-14} \exp (-1,275/T) \text{ cm}^3 \text{ s}^{-1}$.

Before the work of Zahniser and Howard⁶ the only measurements of the rate coefficient for reaction (2) were the indirect competitive ones of Simonaitis and Heicklen⁷ and DeMore and Tschukow-Roux⁸, who measured the ratio $R = k_2/(k_3)^{1/2}$ where k_3 is the rate coefficient for the reaction

The measured ratios are presented in Table 1. To estimate the rate for reaction (2) from these ratios, one must have information about the value of k_3 . For example, the NASA CFM Workshop report⁴ recommended a temperature independent value for k_3 of $2.5 \times 10^{-12} \text{ cm}^3 \text{ s}^{-1}$ with an estimated uncertainty of a factor of 2 for reaction (3). This rate constant was based on the simultaneous consideration of the best available rate data for several related hydrogen radical reactions⁴. Cox⁹, however, has since reported a large negative activation energy for reaction (3); his measured rate constant is $(1.4 \pm 0.7) \times 10^{-14} \exp [(1,650 \pm 205)/T] \text{ cm}^3 \text{ s}^{-1}$. Based on the newest data collected for reaction (3) and the R values of Simonaitis and Heicklen⁷ and DeMore and Tschukow-Roux⁸, we can infer a much less marked temperature dependence for reaction (2) than was recommended in the CFM Workshop report⁴. Moreover, Hamilton *et al.*¹⁰ have found that the HO_2 radical involved in reaction (3) can readily cluster with water molecules—substantially accelerating the apparent rate of the reaction. Therefore the laboratory results obtained for R are expected to be complicated by HO_2 cluster reactions. Table 1 combines the kinetic data uncertainties for reaction (3) to estimate the 220 K (stratospheric) rate coefficients corresponding to each of the sets of available laboratory data. Note that the range of values of k_2 in Table 1 based on the measurements of Zahniser and Howard⁶

Table 1 Stratospheric $\text{HO}_2 + \text{O}_3$ reaction rate coefficient ($\text{cm}^3 \text{ s}^{-1}$)

Data source	$R = k_2/(k_3)^{1/2}$	k_2 (220 K) upper limit	k_2 (220 K) lower limit
Ref. 6	—	2.0×10^{-15}	4.5×10^{-16}
Ref. 4	—	4.4×10^{-16}	1.1×10^{-16}
Ref. 7	$1.2 \times 10^{-8} \exp (-1,000/T)$	$2.8 \times 10^{-16*}$	$1.4 \times 10^{-16*}$
		$1.3 \times 10^{-15}†$	$2.8 \times 10^{-16}†$
Ref. 8	$1.1 \times 10^{-7} \exp [-(1,550 \pm 250)/T]$	$6.7 \times 10^{-16*}$	$3.4 \times 10^{-17*}$
		$2.9 \times 10^{-15}†$	$6.9 \times 10^{-17}†$

* Based on the CFM Workshop⁴ recommended value for the rate coefficient for the reaction $\text{HO}_2 + \text{HO}_2$ of $2.5 \times 10^{-12} \text{ cm}^3 \text{ s}^{-1} \pm$ factor of 2.

† Based on Cox's⁹ rate coefficient for the reaction $\text{HO}_2 + \text{HO}_2$ of $(1.4 \pm 0.7) \times 10^{-14} \exp [(1,650 \pm 205)/T] \text{ cm}^3 \text{ s}^{-1}$.

roughly coincides with the range of values deduced from the ratio measurements when Cox's effective rate for reaction (3) is adopted. In this sense, the previous measurements support the new, larger value for the rate coefficient k_2 .

We use a two-dimensional model of stratospheric trace constituents for our calculations^{11,12}. The model lies in a meridional plane extending from 80° N to 80° S latitude and from the Earth's surface to 60 km altitude. It computes the concentrations of 35 constituents and simulates meridional and vertical transport by seasonally variable large scale bulk motion and eddies. Except for reaction (2), the chemical rate coefficients employed are those recommended in the NASA CFM Workshop report⁴.

Figure 1 compares the measured latitude-dependent total ozone column densities in summer (a) and in autumn (b) in the Northern Hemisphere¹³ with the corresponding computed densities for both the old⁴ and new⁶ rate coefficients for reaction (2). Figure 2 shows two of the corresponding vertical concentration profiles of ozone at 0° and 45° N latitude in autumn for these two rate coefficient values of reaction (2). Note that the agreement between theory and measurement has improved more at high latitudes than at low latitudes. This latitude

Fig. 1 Total vertical column densities for a, summer and b, autumn in the Northern Hemisphere. The solid lines correspond to the CFM Workshop⁴ recommended value of the rate coefficient for the reaction of HO_2 with O_3 . The broken lines correspond to the rate coefficient reported by Zahniser and Howard⁶. The squares represent mean seasonal measured values collated by Wilcox *et al.*¹³.

Fig. 2 Computed and measured ozone concentration profiles at latitudes of *a*, 0° and *b*, 40° N for autumn in the Northern Hemisphere. The squares represent the mean seasonal measured values collated by Wilcox *et al.*¹³. The Goddard data (circles) (I. Eberstein, personal communication) were obtained from satellite measurements of backscattered solar ultraviolet radiation¹⁴. The solid lines correspond to the CFM Workshop⁴ recommended value of the rate coefficient of the reaction of HO₂ with O₃ and the broken lines to the value reported by Zahniser and Howard⁶.

difference occurs because reaction (2) represents a larger fraction of the total ozone loss rate at the higher latitudes.

Reaction (2) represents the dominant catalytic loss process for ozone below 30 km. The dominance of this reaction over NO_x catalytic reactions results mainly from the new reaction rate coefficient for reaction (1). Poppoff *et al.*⁵ discuss the details of the coupled HO_x-NO_x photochemical cycles in the stratosphere for updated chemistry. They also give a sensitivity analysis (of total ozone to the injection of NO_x by supersonic transport aircraft) which is relevant to a study of the effects caused by changes in the HO₂ + O₃ reaction rate constant. Basically, since HO_x chemistry exerts strong control over the ozone abundance in the lower stratosphere, increasing the strength of the HO_x catalytic cycle [by increasing the rate constant for reaction (2)] tends to decrease the stratospheric ozone content.

Thus, we have found that the problem presented by the model predictions of excessive ozone abundances, which occurs when the recently measured value of the rate coefficient for reaction (1) is used, diminished significantly when the newly measured value of the rate coefficient for reaction (2) reported by Zahniser and Howard⁶ was used.

Effect of pressure on the Raman spectrum of ice

THE decrease in the volume of ice on compression or cooling is thought to be due to a decrease in the O-O distances, because the O-O-O and O-H...O angles do not change. The decrease in the IR or Raman frequency of the in-phase O-H stretching vibrations, ν_1 , of ice is thus related to the consequent shortening of the hydrogen bond. It follows that ν_1 should remain constant at a constant volume, if anharmonic effects and the bending of O-H...O angles are insignificant. We report here the effect of pressure on the Raman spectral region of O-H stretching in hexagonal ice and discuss it in terms of explicit temperature and volume effects.

A cylindrical steel vessel with three 1-cm thick sapphire windows was used as the high pressure optical cell. The 5-mm diameter, 20-mm long sample of polycrystalline ice was mounted on the inside of one sapphire window with the cylindrical axis along the direction of the laser beam of power level 700-800 mW of the 4,880-Å excitation line. The optical cell was filled with Dow-Corning silicone oil, which acted as the pressure-transmitting fluid. The scattered light was collected at 90° to the laser beam and its intensity was measured with a calibrated Jarrel-Ash model 25-400 laser Raman spectrometer using a spectral slit width of 7-8 cm⁻¹.

Typical Raman spectra in the O-H stretching region (2,800-3,600 cm⁻¹) are given in Fig. 1. The features of the spectrum at high temperatures are relatively broad, because of the increase in the distribution of energy states, but they are essentially similar to those in the spectra measured below 100 K in our own study, or in the literature^{1,2}. In Fig. 1, the spectral features of ice remain unaffected by the presence of silicone oil, but two additional peaks appear at about 2,904 and 2,966 cm⁻¹ due to the C-H stretching mode in silicone. Application of pressure to ice at 258 ± 0.3 K decreases the frequency of the O-H stretching peak from 3,145 cm⁻¹ at 1 bar to 3,127 cm⁻¹ at 1.25 kbar.

A plot of ν_1 against pressure P at 255.2 ± 0.3 K is shown in Fig. 2. The $(\partial\nu_1/\partial P)_T = -13.7$ cm⁻¹ kbar⁻¹, a value which shows little systematic dependence on temperature in the region 269 > T > 253 K. A plot of ν_1 against temperature at 1 bar is also shown in Fig. 2. The $(\partial\nu_1/\partial T)_P = 0.63$ cm⁻¹ K⁻¹.

The effect of temperature on ν_1 at constant pressure may be divided into the constant-volume temperature effect, $(\partial\nu_1/\partial T)_V$, and the constant-temperature volume effect, $(\partial\nu_1/\partial V)_T$ by the equation

$$(\partial\nu_1/\partial T)_P = (\partial\nu_1/\partial T)_V + (\partial\nu_1/\partial V)_T(\partial V/\partial T) \quad (1)$$

$$(\partial\nu_1/\partial V)_T(\partial V/\partial T) = -(\alpha/\beta)(\partial\nu_1/\partial P)_T \quad (2)$$

where α is the volume expansivity and β the compressibility. At 255 K, $\alpha = 155$ MK⁻¹ (ref. 3) and $\beta = 12 \pm 1$ Mbar⁻¹ (ref. 4). From Fig. 2, $(\partial\nu_1/\partial P)_T = -13.7$ cm⁻¹ kbar⁻¹, and $(\partial\nu_1/\partial T)_P = 0.63$ cm⁻¹ K⁻¹. Substituting in equations 1 and 2, one obtains $(\partial\nu_1/\partial T)_V = 0.45$ cm⁻¹ K⁻¹. Thus the change in the O-H stretching frequency of ice with temperature near 255 K is about 30% due to the change in volume with temperature and about 70% due to the change in temperature alone. Thus the Grüneisen constant for the O-H stretching vibrations, $\gamma = -(\partial \ln \nu_1 / \partial \ln V)$, calculated from the above values is -0.36 at 255 K.

From the compressibility of ice⁴, the change in O-O distance with pressure, $(\partial R_{O-O}/\partial P)_T = -9$ Å Mbar⁻¹ at 255 K, where R_{O-O} is the O-O distance. From the R_{O-O} data⁵ adjusted to the

Fig. 1 Raman spectrum of hexagonal ice at 258 ± 0.2 K in the O-H stretching region. *a*, Ice held in air; *b*, immersed in silicone oil at 1 bar; and *c*, immersed in silicone oil at 1.25 kbar. Arrows point to the frequencies of the C-H stretching in silicone. Note also the slight increase in the C-H stretching frequencies with pressure.

density calculated from crystallographically determined expansivity³ of ice, the change in R_{O-O} with temperature, $(\partial R_{O-O}/\partial T)_P = 116 \text{ Å MK}^{-1}$ at 255 K and 1 bar. Combining them with the values of the slope of the plots in Fig. 2, one obtains $(\partial \nu_1/\partial R_{O-O})_P = 5,430 \text{ cm}^{-1} \text{ Å}^{-1}$ and $(\partial \nu_1/\partial R_{O-O})_T = 1,520 \text{ cm}^{-1} \text{ Å}^{-1}$. So, for the same amount of decrease in O-O distance, isobaric cooling decreases ν_1 3.5 times more than does isothermal compression near 255 K.

The increase in ν_1 with temperature at a constant volume (or constant R_{O-O}) is of principal interest. The relatively high

Fig. 2 The frequency of the in-phase O-H stretching vibration, of hexagonal ice plotted against temperature at 1 bar at the top and against pressure at 255 ± 0.3 K at the bottom. Filled triangle is from an isotropic spectrum from ref. 12.

positive value of $(\partial \nu_1/\partial T)_V$ indicates either or all of the following three: (1) the lengthening of the hydrogen bond with increasing temperature; (2) an unusual effect due to the anharmonicity of the potential energy of O-H stretching; (3) the weakening of the intermolecular coupling of O-H stretching motions, when the O-O distance remains constant. The lengthening of the hydrogen bond can occur either by the bending of O-H...O angles or (but less likely) by a shortening of O-H distance if the O-H...O bond were to remain linear. The force constant for the O-H...O bending in ice is small⁶ and the IR frequencies of librational modes indicate that the energy required to bend the O-H...O angle becomes smaller as the temperature increases. If lengthening of the hydrogen bond occurs, the energy required to break the hydrogen bond would decrease and the activation energy of dielectric relaxation at a constant volume should therefore decrease with increasing temperature. The following consideration shows that it is so. The activation energy at constant volume, E_v^* , and constant pressure, E_p^* are related by

$$E_p^* = E_v^* + (\alpha/\beta)T\Delta V^* \quad (3)$$

where ΔV^* is the volume of activation. Differentiating equation (3) with respect to temperature:

$$(\partial E_p^*/\partial T)_P = (\partial E_v^*/\partial T)_V + (\alpha/\beta)\Delta V^* + (T\Delta V^*/\beta)(\partial \alpha/\partial T)$$

For ice near 255 K, $\Delta V^* = 3 \text{ ml mol}^{-1}$ (ref. 7), $(\partial \alpha/\partial T)_P = 7.39 \times 10^{-7} \text{ K}^{-2}$ (ref. 8), and $(\partial E_p^*/\partial T)_P$ is zero⁹. Therefore, $(\partial E_v^*/\partial T)_V = -9 \text{ J mol}^{-1} \text{ K}^{-1}$.

The simplest consideration of anharmonicity leads one to a negative value of $(\partial \nu_1/\partial T)_V$, for anharmonicity generally reduces the force constant and consequently the frequency of a vibrational mode, when a system is excited to higher energy levels by raising the temperature at a constant volume. It is conceivable that terms higher than the cubic predominate in the potential energy of O-H stretching and thus anharmonicity may play a greater role in determining the temperature dependence of ν_1 . The intermolecular coupling of O-H vibrations at a constant volume is affected by both the lengthening of the hydrogen bond and the anharmonicity of the potential energy. Its magnitude is difficult to assess without the knowledge of the other two effects.

The above results are significant because it is widely believed that the vibrational frequencies depend largely on the volume and because the results may be helpful in a detailed analysis of the vibrational spectrum of both the crystalline^{10,11} and vitreous ices² from the point of view of solid state spectroscopy. They are of further value, because the corresponding measurement of the IR spectra of hexagonal ice is difficult.

Collection of atomic mercury by electrostatic precipitators

ELECTROSTATIC precipitators are widely used to remove dust particles from gases and the mechanism of this is well understood. One major application is in the cleaning of a sulphur dioxide produced in smelting of metalliferous sulphide ores before its conversion to sulphuric acid and the precipitated material is often found to contain mercury. We have shown that the concentration of mercury is below the saturation level and therefore present as atoms so the accepted mechanism for solid particle collection is not involved in mercury removal. We have investigated the phenomenon in the laboratory using air as the carrier gas at room temperature, and by large scale tests carried out in an 800 tonne d^{-1} sulphuric acid plant treating the gases formed by roasting zinc sulphide concentrate. In both types of test a discharge wire and earthed collector tube precipitator configuration was used. In the plant tests the roaster gas contained 9% sulphur dioxide and was saturated with water. In both the laboratory and plant tests the gas streams were unsaturated with respect to elemental mercury vapour.

Flameless atomic absorption spectroscopy was used to measure the difference in the mercury concentration of gas entering and leaving a precipitator. This technique is specific for the detection of discrete gaseous atoms, which suggests that gaseous atomic mercury, and not particles containing mercury, is removed by electrostatic precipitators.

In our tests, mercury was only collected during or after generation of a corona discharge (Fig. 1). When nitrogen was used as a carrier gas, mercury was not collected because nitrogen will not sustain a corona discharge¹.

We postulate that in the corona discharge, high energy ions bombard the electrode surfaces and disrupt a passivating layer, such as an oxide, hence producing a more reactive surface. When mercury atoms diffuse to the electrode surface they are adsorbed on the active sites.

Mercury was collected by both electrodes, irrespective of discharge wire polarity, and by a variety of electrode materials including lead, copper, tin, aluminium and stainless steel.

Following voltage application, mercury collection efficiency increased gradually to a steady-state value which was independent of the electrode material. The time taken to achieve the steady-state condition with respect to the mercury collection varied with electrode material (Fig. 1), reflecting the time required to clean electrode surfaces of different chemical composition. The extent of cleaning, and hence the steady-state mercury collection efficiency, depended on the voltage. Mercury

Fig. 1 Time dependence of elemental mercury collection in an electrostatic precipitator. *a*, Voltage on 880 kV m^{-1} ; *b*, voltage off, air velocity, 0.084 m s^{-1} . $\times$, Copper tube; $\circ$, aluminium tube both 35 mm diameter.

Fig. 2 Variation of mercury collection efficiency with precipitator specific collecting area at constant electrical field strength. $\times$, Tube radius 8 mm, electrical field strength 800 kV m^{-1} ; $\circ$, tube radius 23 mm, electrical field strength 520 kV m^{-1} .

collection continued after the voltage had been switched off (Fig. 1) the efficiency of collection decreasing continuously to zero as the electrode surfaces passivated. The rate at which the efficiency of mercury collection decreased was substantially slower than the decay of the precipitator voltage. If the collection of mercury ions was involved, mercury collection efficiency would have decreased discontinuously when the voltage was switched off, because ions would only be formed when the voltage was applied.

For a precipitator operating with a negative discharge wire and an earthed collector tube, the efficiency of atomic mercury collection can be described by equation (1), which is derived from the Deutsch equation²

$$E = 100[1 - \exp(-k2h/rv_g)] \quad (1)$$

where E is the percentage efficiency of mercury collection, r and h are the collector electrode tube radius and length, respectively, v_g is the axial gas velocity, and $(2h/rv_g)$ is the specific collecting area of the precipitator (electrode surface area/gas flow rate), and k is a complex function incorporating the rate of transport of mercury atoms to the electrode surfaces and their probability of collection. k varies with tube radius and voltage according to equation (2)

$$k = AV/2r \quad (2)$$

where A is a constant for a given tube radius and V is the applied voltage.

Equation (1) was verified experimentally (Fig. 2) over a wide range of conditions ($r=8.0$ – 45 mm for laboratory and $r=75$ mm for plant tests). A maximum mercury collection efficiency in excess of 99% was achieved. The efficiency of

mercury collection was independent of the mercury concentration in gas entering the precipitator for concentrations in the range 0.1–8 mg m⁻³.

At very high discharge voltages equation (1) may over-estimate mercury collection efficiency because the gaseous ions bombarding the electrode surfaces can become sufficiently energetic to desorb collected mercury. In the absence of a corona discharge, no mercury was released when mercury-free air was passed through a precipitator which had previously been used to collect mercury, proving that mercury was bound to the electrode surfaces. However, when a discharge voltage greater than the threshold value for which equation (1) is valid was applied, mercury was desorbed into the mercury-free air. The threshold voltage for mercury desorption was independent of electrode material.

For precipitators operating at a constant voltage below the threshold voltage for mercury desorption, A and hence k (equations (1) and (2)) increases with decreasing tube radius for $r < 35$ mm, but seems to be independent of tube radius when $r > 35$ mm. Because k increases as r decreases below 35 mm the electrode area required for a given application can be decreased by designing a precipitator with a very small electrode separation.

We suggest that electrostatic precipitators with smaller than normal electrode separations would be capable of removing mercury and perhaps other volatile environmentally undesirable elements, such as selenium and tellurium, which are present as vapour in the gas streams produced during the processing of ores and the burning of certain types of coal.

Molecular morphology of polyethylene determined by NMR

SOME of the earliest applications of nuclear magnetic resonance (NMR) concerned molecular structural determinations in the solid state via proton NMR second moments, a sensitive function of the number, types and relative positions of the constituent nuclei. This classical technique has been extended to polymeric solids, but it has not previously been exploited to address the problem of molecular morphology in polymer crystals. We describe here a framework for the interpretation of such measurements in cocrystals of polyethylene (PEH) and perdeuteropolyethylene (PED) and present preliminary experimental data. The potential of this technique for distinguishing between adjacent re-entry and random re-entry molecular morphologies on a very local scale complements the ability of small angle neutron scattering (SANS) to ascertain the larger scale configuration of the polymer chain.

The bulk morphology in semicrystalline polymers is well understood. It can be described superficially as a dispersion of crystalline lamellae (with dimensions of the order of 10⁻⁶ m on the edges and 10⁻⁸ m in thickness) in an amorphous matrix. By contrast, only a limited number of features of the molecular morphology within the lamellae have been unequivocally defined^{1,2}, and these are all functions inherent in the primary

Fig. 1 The melt endotherm for an etched, solution-crystallised polyethylene co-crystal with $x^0 = 0.53$; heating rate 5°C per min; DuPont 990 thermal analyser. The PED aggregates in the co-crystal. The low temperature shoulder, approximately 15% to 25% of the total endotherm, is attributed to the PED phase resulting in a range for the mole fraction of PEH in the co-crystal, $x = 0.64$ to 0.72 . (Note, our observed melting point for quenched, unetched PEH is 136°C.)

structure of the polymer: (1) the extended, low energy chain conformation; (2) the lateral juxtaposition of the chains; and (3) the orientation of the rectilinear chain axis normal to the lamella surface.

The latter feature has prompted controversial hypotheses to explicate the mode of re-entry of a polymer chain into the lamella surface, a 001 lattice plane. The adjacent re-entry (AR) model posits a series of regular folds (180° turns) that dictate re-entry of the chain into the lamella at an adjacent, nearest-neighbour site in the 001 plane³. The random re-entry (RR) or 'switchboard' model imposes no such external constraints on the trajectory of the chain. The RR model stipulates that, on emerging from the lamella, the chain either (1) re-enters the same lamella at a random site, which could be far removed from the point of emergence (subject to the stereochemical and linear dimensional constraints of the polymer chains) or, (2) permeates the interlamellae amorphous matrix and enters a neighbouring lamella^{4,5}.

Recent SANS investigations of co-crystallised mixtures of PED and PEH have rekindled this controversy⁶ and have been used as supporting evidence for both the AR^{7,8} and the RR^{9,10} models, depending on the method of sample preparation. By way of circumventing this interpretive dilemma we pursue a different experimental approach to the problem—NMR, a sensitive technique for probing the local environment of a molecule. Proton NMR second moment measurements¹¹, typically used to investigate the bulk morphology¹² and relaxation processes¹³ in semicrystalline polymers, provide an entree to the problem.

For protons in a polycrystalline sample, the second moment is¹⁴

$$M_2 = \frac{3}{4} \gamma^2 \hbar^2 I(I+1) \frac{1}{N} \sum_{j,k} (r_{jk})^{-6} \equiv M_2^a + M_2^i \quad (1)$$

where γ is the proton gyromagnetic ratio, its spin $I = 1/2$, N is the number of nuclei in the sum and r_{jk} is the distance between nuclei j and k . In equation (1) we decompose M_2 into its intramolecular part M_2^a and its intermolecular part M_2^i . The former can be calculated from the molecular structure and conformation, the latter from the crystal structure. (In the polymer crystal, we will consider the analogous quantities, the intra- and interstem contributions to M_2 , where the term 'stem' refers to a single traverse of the chain through the lamella.) Non-resonant nuclei I' can also contribute to M_2 but with an additional reduction factor (relative to protons)¹⁵:

$$M_2' = \frac{4}{9} \frac{I'(I'+1) \gamma'^2}{I(I+1) \gamma^2} M_2 \quad (2)$$

where I' and γ' are characteristic of the non-resonant nucleus.

For deuterium ($I' = 1$), this reduction amounts to $\cong 0.02$ of that anticipated from protons at comparable r_{jk} .

Samples of co-crystallised PEH and PED (molecular weights 2.0×10^5 and 2.8×10^5 , respectively) were prepared in two ways: in Method I, quenched polyethylene, 1% solutions of mixtures of PEH and PED ($x = 1$ to 0.28; x = mole fraction of PEH) refluxed in orthodichlorobenzene for 30 min under N_2 were quenched (precipitated) in an excess of methanol, washed with methanol and dried under vacuum at 65 °C (48 h); in Method II, solution-crystallised polyethylene, a 0.1% solution of PEH and PED ($x = 0.53$) in refluxing orthodichlorobenzene was rapidly cooled (~ 2 min) to 90 °C and allowed to stand (48 h). The resulting crystals were collected at 90 °C, extracted with acetone in a Soxhlet (24 h) and dried as in Method I. In order to exclude contributions to M_2 originating from the amorphous fraction of the polymer (see Fig. 2) all samples were subjected to a fuming nitric acid etching procedure (80 °C for 96 h); the highly crystalline debris was washed in H_2O , extracted with acetone (24 h) and dried under vacuum at 65 °C (24 h).

For all co-crystals calibrated NMR intensity measurements show that $\bar{x}$, the mean mole fraction of PEH in the co-crystal, is identical to that initially present in the solution blend, x_0 , that is, PEH (PED) is not partitioned preferentially into the amorphous phase and lost during etching. Aggregation of PEH (PED) into distinctly separate phases can be checked by examining the melting endotherms of the co-crystals⁹. Single endotherms are observed for quenched, etched co-crystals. A shoulder on the low temperature side of the endotherm is indicative of PED aggregation in the co-crystal. In the case of solution-crystallised mixtures of PEH and PED, the aggregation of the PED is pronounced (Fig. 1). In the resulting co-crystal, the local mole fraction of PED, x , is obviously not the same as x_0 . We have graphically decomposed this endotherm into two components, the melting of a PEH/PED co-crystal at 126 °C and the melting of aggregated PED at 122 °C. We estimate that the PED aggregate accounts for 15% to 25% of the entire endotherm

Fig. 2 The proton FID signal in polyethylene following a $90^\circ_0 - \tau - 90^\circ_{90}$ pulse sequence. The signals were obtained with a Bruker pulse spectrometer at 30 MHz; 90° pulse length = 1.5 μ s; $\tau = 10$ μ s; $T = 20$ °C. Typically 256 FID signals were averaged using a Biomation 802 digitiser and a Nicolet 1072 signal averager. $\circ$, Experimental FID. *a*, Quenched PEH. *b*, Quenched and etched PEH: $\bullet$, computed FID

and, assuming the same ΔH for PEH and PED, x ranges from 0.64 to 0.72 for this co-crystal. From the melting points of these co-crystals we estimate lamellae thicknesses of 150 Å and 180 Å for solution quenched and solution-crystallised samples, respectively¹⁶.

The NMR absorption line shape and the free induction decay (FID), $F(t)$, are related by a Fourier transform. Even moments M_n of the resonance line shape are related to the coefficients of an even power series expansion of $F(t)$ as¹⁵

$$F(t) = \sum_{n, \text{even}} \frac{M_n t^n}{n!} \quad (3)$$

A fit of the observed FID to this power series was used to compute the second moments. Figure 2 contrasts the FIDs of unetched and etched PEH and illustrates a computed fit to equation (3). The value for M_2 obtained from quenched PEH at 20 °C is $26.3 \pm 0.5 G^2$, and lowering the temperature to -150° produced no observable changes in M_2 . As noted previously, when the amorphous fraction is etched from PEH, the rigid lattice limit obtains at 20 °C (refs 17, 18). The observed M_2 is, however, larger than that previously reported for etched PEH after correcting for thermal expansion of crystal lattice ($24.3 \pm 0.5 G^2$).¹⁷ While the reproducibility of M_2 is excellent, the absolute magnitude computed from the FID is limited by the accuracy of determining the position of the dipolar echo ($t = 0$) following the $90^\circ_0 - \tau - 90^\circ_{90}$ pulse sequence. Once a procedure for determining $t = 0$ is established, relative values of the second moment, $R = M_2/26.3$, can be confidently compared.

Isotopic dilution experiments can be used to separate R into the intra- and interstem contribution to M_2 , R^a and R' , respectively. The interstem contribution is scaled by the conditional probability $P(H|H)$ that a given nearest-neighbour (site) of a protonated species is also protonated. In order to extract the details of the molecular morphology in the lamellae we calculate S , the interstem contribution to M_2 per site in the crystal relative to that for pure PEH, for the following models of chain re-entry: (1) AR, adjacent reentry with no restrictions on the direction of chain propagation in the 001 plane of the lamella; (2) AR-110, adjacent re-entry with the chain restricted to enter the lattice along the 110 planes; (3), AR-100, adjacent re-entry restricted to the 100 planes; (4) RR, random re-entry of the chain.

In the 001 plane of the crystal each lattice site has six adjacent sites, two along the 100 plane and two each along the 110 and $\bar{1}\bar{1}0$ planes. The absolute computed interactions along the crystal planes, $^{100}M'_2$ and $^{110}M'_2$ depend on the lattice cell constants. However, over a range of cell dimensions the relative interactions $^{ijk}R' = ^{ijk}M'_2/M'_2$ remain invariant: $^{100}R' = 0.13$ and $^{110}R' = ^{1\bar{1}0}R' = 0.186$.

For the AR model, around each PEH site at least two adjacent sites must also contain PEH chains ($P(H|H) = 1$, ignoring chain ends). We assume that chains with just two self-adjacent sites occur with a probability of 1/3. For multiple self-adjacent re-entries (3, 4, 5, or 6) about a given site we assign a probability of 1/6. The relative contribution S is obtained from the probability weighted sum of $^{ijk}R'$ arising from the different possible configurations about a given site. For the above parameters, one obtains

$$S(\text{AR}) = \frac{22}{36} + \frac{14}{35}x \quad (4)$$

In the AR-110 model, $^{110}P(H|H) = 1$ and $^{100}P(H|H) = ^{1\bar{1}0}P(H|H) = x$. Thus

$$S(\text{AR-110}) = 2^{110}P(H|H)^{110}R' + 2[^{1\bar{1}0}P(H|H)^{1\bar{1}0}R' + ^{100}P(H|H)^{100}R'] \quad (5)$$

$$= 0.37 + 0.63x$$

Similarly, $S(\text{AR-100})$ is given by

$$S(\text{AR-100}) = 0.26 + 0.74x \quad (6)$$

Fig. 3 The relative second moment R plotted against x for solution-quenched and etched co-crystals of PEH and PED; $x = \bar{x} = x_0$ for all samples. The solid line is a linear regression fit to the data with a correlation coefficient of 0.86; $R(x=0) = 0.62 \pm 0.04$; $R(x=1) = 0.98 \pm 0.04$.

Finally, in the RR model, where $P(H|H) = x$ for all sites we obtain

$$S(\text{RR}) = x \quad (7)$$

In each of these models the contribution that PED chains in adjacent sites makes to M_2' can be obtained with equations (4)–(7) by replacing x with $(1-x)$ and multiplying the result by 0.02.

To determine which model corresponds to the experimental data, we consider the behaviour of the relative second moment with the isotopic content of the co-crystals. R should be a linear function of x for all the models if the co-crystals are homogeneous. The intercept consists of the intrastem contribution plus the residual interstem contributions characteristic of the molecular morphology. Our procedure is to compute R^a from the intercept of R versus x for the quenched PEH/PED co-crystals (Fig. 3) and the expressions for S of equations (4)–(7) according to

$$R^a = [(R - S)/(1 - S)]_{x=0} \quad (8)$$

The values of R^a computed in this fashion are 0.02, 0.40, 0.47, and 0.62 ± 0.04 respectively, for the AR, AR-110, AR-100 and

Fig. 4 The relative intermolecular contribution to M_2 , S , plotted versus x , the mole fraction of PEH in co-crystals of PEH + PED. $\circ$, Quenched, etched co-crystal; $x = x^0 = 0.53$. $\bullet$, Quenched, annealed (123 °C; 48 h), etched co-crystal; $x = x^0 = 0.53$. $+$, Solution-crystallised, etched co-crystal; x ranges from 0.64 to 0.72 (see Fig. 1).

RR models of chain re-entry. These values of R^a can be compared with the values for R^a calculated for plausible structural and lattice parameters. It should be noted that calculated values for R^a are extremely sensitive to the choice of the bond angles and bond lengths used to compute M_2' (ref. 13). The calculated values of R^a range from 0.67 to 0.73. Thus, from the magnitude of the intercept, there is strong evidence for a random molecular dispersion of PEH in PED characterised by the RR molecular morphology in the quenched co-crystals. The observed $R^a = 0.62 \pm 0.04$ is lower than anticipated and probably reflects, as suggested by Olf and Peterlin,¹⁷ a decrease in M_2' caused by the presence of $-\text{COOH}$ and $-\text{NO}_2$ groups near the chain ends at the etched lamella surface. On the other hand, heterogeneity due to phase separation in the co-crystals would, for a given x^0 , yield larger experimental values for R and result in a correspondingly larger apparent R^a .

Now we consider the relative interstem contributions to M_2 . In Fig. 4 the calculated values of S (equations (4)–(7)) are shown plotted against x for the four models of chain re-entry. Also shown are three experimental values for relative interstem second moments derived from $S = (R - R^a)/(1 - R^a)$ with $R^a = 0.64 \pm 0.04$. The experimental values correspond to PEH/PED co-crystals ($\bar{x} = x^0 = 0.53$) that differ in their methods of preparation. Both samples of the solution-quenched co-crystals (one annealed at 123 °C for 48 h before etching) exhibited single, sharp melting endotherms indicative of homogeneous co-crystals characterised by $x = \bar{x}$. According to Fig. 4, within the experimental uncertainty, the annealing treatment does not significantly perturb the RR molecular morphology in the solution-quenched co-crystals. In the solution-crystallised sample, the fact that $\bar{x} = x_0$ merely indicates that the crystallisation was carried out to 100% conversion. Severe compositional heterogeneity can occur in solution-crystallised mixtures of PEH and PED¹⁹. However, the profile of the melting endotherm of this sample (Fig. 1) prompts us to suggest that only two phases are present: one, pure PED crystals ($x = 0$), comprising 15% to 25% of the sample, the other, co-crystals of PED and PEH characterised by $x = 0.68 \pm 0.04$. For this compositional distribution, the RR model again accounts for the observed value of S . (Note that using a value of $R^a > 0.64$ yields smaller values for S .)

In contrasting the observed values of S with the predictions of the model morphologies, the procedure used does presume compositional homogeneity, that is, x must be representative of the distribution of PEH throughout the macroscopic sample of co-crystals. In heterogeneous samples, specification of the distribution of composition is prerequisite to the extraction of molecular details from measurements of intensive parameters such as NMR second moments. (One can, for example, arrive at the observed value of S for the solution-crystallised co-crystal with the AR-110 morphology assuming that the low melting fraction (Fig. 1) has $x = 0.2$ and the remaining fraction is characterised by $x = 0.6$; $\bar{x} = 0.53$ for the entire sample.)

In conclusion, the NMR second moment data provide another perspective on the nature of the molecular morphology in polyethylene. The NMR experiments, unaffected by the overall configuration of the chains, complement the neutron scattering experiments in the sense that they selectively probe the local short-range structure. The NMR reconstruction of the mode of chain re-entry into the lamella appears to be independent of the method of sample preparation. While unequivocal data on solution-crystallised polyethylene requires compositionally homogeneous co-crystals (perhaps accessible through fractional crystallisation), these preliminary NMR results argue against theories of regular chain re-entry. Most significantly, the NMR method should be able to discriminate among less ideal models of molecular morphology, that is, two (three, ...) AR stems followed by a random trajectory, followed by another sequence of AR stems, and so on, until the entire polymer chain is incorporated in the crystal.

We thank C. E. Tarr for advice on data reduction and D. L. Vanderhart for constructive criticisms. This work was supported

in part by a grant from the National Institute of Arthritis, Metabolism and Digestive Diseases (AM 17497). R.I.C. is an Alfred P. Sloan Fellow.

Note added in proof: R. Voelkel and H. Sillescu have independently applied the NMR isotopic dilution method to PEH and observe the molecular morphology to be molecular weight dependent (manuscript in preparation).

Soil stabilisation by cellulose xanthate

CELLULOSE XANTHATE is unusually effective in stabilising soil against attrition and deformation. At a concentration of about 0.1% in the soil it reduces erosion; at higher concentrations it can be used to bind soils to improve their mechanical strength. During an investigation of other uses for cellulose xanthate, we recently rediscovered its unusual interaction with soils. We describe here its formation and application in the laboratory, quantitatively compare it with several synthetic polymeric soil conditioners and suggest a mechanism for its action. With regard to the effectiveness of the xanthate soil treatment, its economy and the ready availability of agricultural waste cellulose, we hope to encourage further study of this interesting system.

The initial disclosure of soil stabilisation by cellulose xanthate was a series of patents by Meadows¹, followed by two brief reports by another group^{2,3}. As far as can be determined no further use of cellulose xanthate for soil treatment has been made. A number of other materials have been proposed or used for soil stabilisation, for example, strong composite structures can be made from polymers, asphalt or Portland cement⁴, in amounts of the order of 10% of the soil. At lower concentrations, various hydrophilic polymers, usually polyelectrolytes, can be used as conditioners to stabilise aggregates and improve tilth⁵. Widespread use of soil additives is cost limited. Experience in applying cellulose xanthate should determine whether it is significantly cheaper than additives based on petrochemicals or energy intensive sources.

Cellulose xanthate can easily be made from any cellulosic source that contains accessible alpha cellulose: rice or wheat straw, chemically pulped wood or paper products, cotton, and similar materials. Mechanically pulped wood or papers are not generally useful, as the structure resists solution after xantha-

tion. In this work cellulose xanthate solutions were made from used computer cards, a source of nearly pure fibrous cellulose. The cards (~2.5 g each) were soaked for 10 min in 18% (w/w) aqueous NaOH, drained and padded to dampness with paper towels. The damp alkali cellulose was transferred to a wide-mouth jar, and 1.5 ml carbon disulphide was added for each card. After rapid mixing the jar was tightly closed. Several hours later the xanthate formed an orangish sticky mass at the bottom of the jar. Using a mechanical stirrer, the xanthate was diluted to a 2% solution (based on cellulose content), which was of low enough viscosity to facilitate later measured dilutions. The shelf life of aqueous xanthate solutions is short, a few days at most, so experiments were initiated soon after preparation. Cellulose is regenerable from the xanthate solution by acidification, heating, increasing the ionic strength, or merely by waiting. In soil treatment with xanthate, hastening regeneration is generally unnecessary.

Imperial Valley clay (California) was used to test the stabilising effect of cellulose xanthate. After rough grinding to remove lumps, 20 samples of 20 g each were prepared. This clay was found to form a thick paste when 5–6 ml of water was mixed with 20 g clay. Thus, to obtain a series of samples with known cellulose content, appropriate amounts of the 2% stock solution of cellulose xanthate were diluted to about 5 ml and mixed with the clay. By this method, treatment levels of 0.01, 0.025, 0.05, 0.1, 0.25 and 0.5% cellulose (dry weight) were added to the clay. Two control samples were similarly prepared with water only. Partially dried treated clay was stirred to form irregular balls about 1 cm in diameter. After air drying and curing for a minimum of 24 h at room temperature, the aggregates were sized to pass a 2 mesh (12.7 mm) but not an 8 mesh (3.2 mm) screen. The dry weight of each sample of sized aggregates was redetermined.

To estimate relative stability, a sample was placed in a 236-ml bottle with 125 ml of water. After 1 min, the bottle was rotated end over end at 30 r.p.m. The dry weight of fines that passed through a 20 mesh (1.3 mm) screen was determined after agitation periods of 1, 4, and 16 min. Weight losses are given in Table 1.

For comparison, two synthetic polymeric soil conditioners were also tested: polyvinyl alcohol (PVA) and a hydrolysed polyacrylonitrile (HPAN). These conditioners were applied at the same treatment levels as the cellulose xanthate and tested in the same way with the rotating agitator. Results are also shown in Table 1.

Qualitative differences in texture were noted among the various treatments after drying: both the xanthate and HPAN treatments gave distinctly hardened aggregates, whereas the PVA produced more crumbly material. At higher treatment levels the xanthate-treated soil was especially firm when wet, with a rubber-like springiness. The weight loss during agitation also occurred differently among the three treatments. The rotatory test was rather harsh and, as the test progressed, xanthate-treated and to a lesser extent HPAN-treated aggregates tended to become rounded, while the PVA treatment gave irregular aggregates that gradually broke up. Weight loss of the xanthate-treated clay is, in most cases, substantially less than that of the PVA- or HPAN-treated clay (Table 1).

The mechanism of soil stabilisation by cellulose xanthate may be unique in that it seems to depend initially on adsorption as a polyelectrolyte and then later on the regeneration of cellulose. The behaviour of cellulose xanthate as a polyelectrolyte is well known⁶, as is the effectiveness of polyelectrolytes in binding together clay particles⁷. The xanthate as applied is the ionised sodium salt of the polyanion; hence, its initial interaction with soils should be largely by adsorption to the surface of the clay component. This is apparent from the immediate stabilisation of clay by xanthate, noticeable even when still wet; this rapid stabilisation does not occur with sands.

After some time, most of the xanthate is regenerated to cellulose; cellulose fibrils then presumably take the place of adsorbed xanthate to bridge between particles and confer

Aggregates and stabilisers were agitated in water for 1, 4 or 16 min after an initial 1 min static soak. Stabilisers used were cellulose xanthate (Cell), polyvinyl alcohol (PVA), and hydrolysed polyacrylonitrile (HPAN). Xanthate was prepared as described in the text. The PVA was Du Pont 'Elvanol' polyvinyl alcohol, grade 72-51, 98.5-100% hydrolysed, MW 54,000. HPAN was obtained from a sample of 'Ortho-Til' (Ortho), designated as 83% HPAN; the sample was identified as sodium polyacrylate.

stability. Evidence for the shift from polyelectrolyte sorption in the xanthate form to binding by regenerated cellulose is afforded by analysis for oxidisable sulphur remaining in the treated samples. The analytical method was based on oxidising divalent sulphur by hydrogen peroxide to form the sulphate⁸, after which a slight excess of barium ion was added, and the decrease in soluble barium determined by atomic absorption⁹. Table 2 shows the oxidisable sulphur thus determined for a kaolin sample initially treated with cellulose xanthate to a cellulose level of 0.5%. The results are also given as weight per cent cellulose xanthate (calculated as cellulose), assuming one xanthate group for each two anhydroglucose monomer units. The initial cellulose content calculated from the sulphur content is 0.8%; the amount over 0.5% may represent sulphur present as excess CS₂. After 700 h, the oxidisable sulphur decreased to 2 mg per 100 g kaolin, representing a xanthate content of 0.01% (calculated as cellulose). As clay stabilisation by xanthate seems permanent (barring microbial action), regenerated cellulose must be the effective binding agent in the long run.

Microbial action may limit some applications. The lifetime and fate of the regenerated cellulose in practical applications are unknown, but it appears to last for at least several months³. In our laboratory, samples have been kept in water for more than six months with no marked change. Appropriate antimicrobial agents may be useful for producing a more permanent treatment.

For some applications of cellulose xanthate, its relatively short shelf life in the presence of water may be objectionable. We have found that drying at room temperature and refrigeration are effective in retarding regeneration to cellulose, although these expedients delay rather than prevent regeneration. The reason for this lies in the numerous side reactions attending xanthate formation, two of the more important being

and

The trithiocarbonate is largely responsible for the orange colour of prepared xanthate; it is a stable salt, as is the carbonate and to a lesser extent the sulphide. These reactions are rather slow¹⁰, evidently slower than xanthate formation, which is complete within a few hours at room temperature. Later, however, the reaction tends to be driven toward the formation of thio-carbonate, or at least to the sulphide/carbonate stage if CS₂ is deficient, with the cellulose xanthate decomposing to supply the necessary NaOH and CS₂, along with cellulose. Reducing the temperature slows regeneration, as does removal of water, since ionic reactions are involved. Meadows¹ found that adding a chemical dehydrating agent (for example, CaO) to the air-dried xanthate permitted stable storage for much longer times. Addi-

tional calcium ion is often beneficial for soil applications and this inexpensive addition should ameliorate the stability problem.

Spraying or sprinkling permits direct application of dilute xanthate solutions to large areas. In test plots of 1-4 m², we produced erosion resistance by applying a 0.4% cellulose solution to a depth of 1 cm, leaving a cellulose content of 0.07% in the soil. From adjacent plots tilted to about 20° angles, the silt runoff from an untreated plot was over 500 times that from a treated plot.

In test plots, treated soil appeared to absorb water more rapidly, indicating an increased permeability. This was verified

Table 2 Oxidisable sulphur content of kaolin treated with cellulose xanthate

Time (h)	Oxidisable sulphur (mg per 100 g kaolin)	% Cellulose xanthate in kaolin calculated as cellulose
0	162	0.82
0.2	149	0.75
1	124	0.63
4	123	0.62
20	83	0.42
44	70	0.35
200	36	0.18
700	2	0.01

The analytical values given for zero time were calculated from analysis of the added xanthate solution.

in the laboratory by measuring the volume absorbed by Imperial silty clay standing under a 1 cm head of water for 16 min. Samples were passed through a hand mill to obtain similar particle size and uniformly packed in 9-cm diameter cans by rapping the perimeter with a small rubber mallet. The surfaces of the untreated and bulk treated clay samples were water wetted to 1 cm depth and dried for 24 h before the test; a third sample was wetted with a dilute xanthate solution to 1 cm depth and similarly dried. Untreated clay absorbed 8 l m⁻² of exposed surface. Clay treated to contain 0.1% cellulose in the top centimetre absorbed 12 l m⁻², and clay treated to contain 0.1% cellulose throughout its bulk absorbed 19 l m⁻².

Soil treated with cellulose xanthate does not appear to affect seed germination and growth, as was observed both from weed growth on the test plots and from germination of wheat seeds in the laboratory. However, if the treated soil is compacted with a roller, a hard surface is produced that seems to inhibit seed germination.

We thank the following from Science and Education Administration: L. B. Grass for clay samples, J. van Schilfgaarde

for bringing the problem of producing 'artificial gravel' to our attention, J. Oster for advice, J. M. Wallace for germination studies and G. Bailey for identification of sodium polyacrylate.

Sedimentation rates determined by ^{137}Cs dating in a rapidly accreting salt marsh

SEA-LEVEL records indicate that the coast of Louisiana and other parts of the Gulf Coast are rapidly subsiding¹. Louisiana is now losing approximately 16 square miles of land per year, primarily to subsidence²; the rates of subsidence vary with location. Vertical marsh accretion is the process which counteracts subsidence and eustatic sea-level rise and prevents marsh deterioration, but, as in Louisiana's salt marshes, the pattern, rate and variability are sufficiently complicated to defy simple prediction. Conditions of marsh development vary throughout the coast, from the modern and Atchafalaya deltas through the abandoned deltas to the Chenier Plain³. In recent years, much of the coastal area such as Barataria Basin has been deprived of river-borne sediment through natural stream diversion and the construction of water-control embankments. In addition, dredging from petroleum operations has altered water flow and sedimentation patterns. The survival and productivity of Gulf Coast marshes depend on the influx and accumulation of sediment that offsets the effect of subsidence and maintains the marsh surface within the tidal range. To predict long-range trends in marsh stability, accurate measurements are needed of both subsidence and sedimentation rates. Information on subsidence is available from tide gauge measurements but no measurements have been made of sedimentation rates in marshland developed on Recent Mississippi alluvium. ^{137}Cs , a fallout product of nuclear testing, has become a useful tool for dating recent sedimentary sequences in lakes⁴⁻⁸. We report here its use in the measurement of sedimentation rates in a Louisiana coastal marsh, the first report of such use in coastal marshes.

Cores were taken from a streamside and inland *Spartina alterniflora* salt marsh and from an adjoining shallow water lake in Barataria Basin in Louisiana (29°13' N, 90°7' W). From the streamside location two sediment cores were taken 7 m inland and 5 m apart parallel to a natural stream. Another set of two cores was taken 45 m inland and 5 m apart parallel to the same stream. A third set of two cores was taken 350 m apart in adjacent Airplane Lake, a shallow 19-hectare lake. Cores were obtained by twisting a thin-walled aluminium cylinder of 15 cm diameter and 53 cm depth into the marsh soil or lake bottom. Compaction was minimal using these relatively large-diameter thin-walled cylinders. The sediment was sectioned into 3-cm increments, dried and ground, and each sample well mixed.

^{137}Cs activity in each section was determined by γ counting of the oven-dried sample using a lithium-drifted germanium detector and multichannel analyser⁹. Organic carbon was determined by dry combustion. Organic matter was estimated by multiplying carbon content by 1.724 (ref. 10). Density was determined from oven-dry sediment in the known volume of each section.

Sedimentation rates were calculated from the peak ^{137}Cs concentration found in the marsh and lake profile which corresponded to 1963, the year of peak ^{137}Cs fallout, and 1954, the first year of significant ^{137}Cs fallout^{6,7}. There should be little mobility of ^{137}Cs in sediment, as it is rapidly adsorbed by clay components of sediment and soil^{8,11}. Also, the sediment captured by the dense marsh grass is unlikely to be reworked.

^{137}Cs profile distributions demonstrate rapid vertical marsh accretion (Fig. 1). The two marsh sites nearer the stream were found to be accreting at a rate of 1.35 cm yr⁻¹. The inland marsh was accreting at a slower rate (0.75 cm yr⁻¹). The inland marsh is beginning to deteriorate into small open water areas, presumably because its vertical accretion rate is not able to compensate for subsidence and eustatic sea-level rise. A tail of ^{137}Cs activity extended below the 1954 marker in the marsh profile but not in the lake profiles. This tail corresponds to the rooting depth of *S. alterniflora* and is probably the result of plant absorption of ^{137}Cs (ref. 10). ^{137}Cs activity was expressed on a volume (pCi per 3-cm section) basis.

The distribution of ^{137}Cs in Airplane Lake cores implies accretion rates of 1.1 cm yr⁻¹. A greater amount of sediment mixing occurred in the lake than in the marsh. One of the lake sites did not have a distinct ^{137}Cs peak. However, the 1954 marker horizon for both cores extended to the same depth. A ^{137}Cs tail was not found in the lake cores, apparently because of the absence of plant roots.

The accretion rates reported here are greater than those found in Atlantic coast salt marshes. Richard¹³ recorded accretion rates of 0.34 cm yr⁻¹ in a Long Island salt marsh using brick dust as a marker layer. Armentano and Woodwell¹⁴, using ^{210}Pb , measured accretion rates of 0.47-0.63 cm yr⁻¹ also in a Long Island marsh. The rapid accretion rates obtained by ^{137}Cs dating for this Louisiana salt marsh approximately equal reported subsidence rates of 1.29 and 1.12 cm yr⁻¹ estimated by tide gauge measurements from 1959 to 1971 in this coastal area at Bayou Rigaud (29°16' N, 89°58' W) and Eugene Island (29°22' N, 91°23' W), respectively¹. Even though there is a net land loss along the coast, vertical accretion is apparently compensating for a portion of the subsidence.

Density of the marsh soils ranged between 0.30 g cm⁻³ and 0.10 g cm⁻³, depending on depth and location (Fig. 2). Density of the lake sediment ranged from 0.45 g cm⁻³ at the surface to approximately 0.65 g cm⁻³ at 50 cm. Both mineral and organic matter contribute to the density values. From density and

Fig. 1 Measured ^{137}Cs profiles at each location. a. Streamside 1 and 2; b. inland 1 and 2; c. Airplane Lake 1 and 2.

Fig. 2 Distribution of mineral and organic material at each location. a, Streamside 1; b, streamside 2; c, inland 1; d, inland 2; e, Airplane Lake 1; f, Airplane lake 2. Light shading, mineral; dark shading, organic.

carbon content of the cores, it is shown that the area vertically accretes through organic detritus accumulation and sediment input. The lake is receiving a larger amount of mineral sediment than the adjacent marsh.

The entrapment and stabilisation of suspended inorganic sediment on the marsh surface by vegetation is an important process in helping to maintain elevation with respect to sea level. The incoming sediment also supplies nutrients for plants which in turn enhance further sediment entrapment and stabilisation. The increased primary production contributes to the organic pool of these peaty marsh soils. Maintenance of a viable marsh is thus affected through aggradational processes of plant growth, organic detritus accumulation and inorganic deposition.

The ^{137}Cs dating technique thus seems to be useful in determining sedimentation rates over the past quarter-century in salt marshes that are rapidly accreting. Sediment deposited on the marsh surface is stabilised by the dense vegetation and, based on the slope of the ^{137}Cs profiles, there is little reworking and no pronounced biogenic disturbance of the deposited sediment.

Seismological and geological aspects of the Mantaro landslide in Peru

ON the evening of April 25 1974 one of the largest landslides known took place in the Mayunmarca valley (12.6°S, 74.6°W), adjacent to the Mantaro River, in the Peruvian Andes (Fig. 1). A total of 1,000 to 1,300 $\times 10^6 \text{ m}^3$ of soil and rock was displaced in successive slides, which occurred within a few minutes of each other. Part of the slide material reached the Mantaro canyon, where a gigantic natural dam was formed. The dam was 3.8 km long extending along the axis of the canyon, 2.5 km wide across the river (Fig. 2), 170 m high from the river bed to the lowest point on the crest, and had a volume of 800 $\times 10^6 \text{ m}^3$. At the time of the slide, the Mantaro River was discharging nearly 150 $\text{m}^3 \text{ s}^{-1}$, and a reservoir was quickly impounded upstream from the dam. At its largest, the reservoir was approximately 32 km long and contained over 670 $\times 10^6 \text{ m}^3$ of water. After 42 days, the reservoir overtopped the natural dam. The high potential of flood damage was minimised by construction of a controlled spillway across the dam.

As a direct result of the slide, the village of Mayunmarca and several farms dispersed over 9.6 km^2 were destroyed. Approximately 400 people lost their lives, but about 200 more would have been killed had they not been evacuated: evacuation had been recommended in November 1973 following a geological study in which the landslide was forecast¹. Large property losses, which included a section of the main road, buildings, and agricultural fields, severely affected the weak economy of this remote region. Large sections of the main road which run parallel to the Mantaro River, were flooded by the reservoir, making the road no longer serviceable.

The Mayunmarca valley is an old glacial valley with a dendritic drainage system, which, before the slide, was formed by several streams cutting fluvial terraces into deep gullies. These streams converged near Mayunmarca and continued to the Mantaro River by the Cochacay gully (Fig. 1). Underground drainage came from the Pumarana River and from the Yanacocha and Minascocha lagoons, located at elevations >4,000 m. The hills surrounding the valley reach altitudes of >4,300 m, while the bed of the Mantaro River is just under 2,500 m in elevation. These hills are mainly formed by Permian sandstones and shales lying on Palaeozoic schist and phyllites, which are the impermeable basement rocks of the Mayunmarca valley. The sandstones and shales are generally overlain by glacial deposits or by unconsolidated, weathered, and permeable Quaternary alluvium over 100 m thick (Fig. 2).

During the geological study that warned of a possible landslide¹, an abnormally large amount of water in the unconsolidated sediments under the Mayunmarca terrace and signs of recent small slides in the flanks of the surrounding hills were noticed. After the landslide, a geological inspection of the area²⁻⁴ revealed water saturation of the unconsolidated sediments and soils, suggesting loss of cohesion of the upper unconsolidated layers resulting from a rise in the water table and an increase in underground flow. This condition aided in triggering the slide and was helped by the steep gradient of the Mayunmarca valley.

The landslide area has had very low seismic activity in the past 70 yr. Only two seismic events were located in this area, both

being of intermediate depth of focus ($h \sim 100$ km). Local and regional seismic activity during the few days before the slide, as recorded at Huancayo (HUA, $\Delta = 82$ km, $AZ = 327^\circ$) and Ñaña (NNA, $\Delta = 240$ km, $AZ = 284^\circ$), consisted of four small earthquakes that occurred >100 km from HUA, and of a magnitude $m_b = 5.8$ earthquake that occurred approximately 660 km southeast of Mayunmarca and about 17 h before the landslide⁵. Earth tremors were reported near the Mayunmarca valley between 03:00 and 04:00 hours and around 21:00 hours

LT on 25 April. The earlier tremor could correspond to the $m_b = 5.8$ regional event, which occurred 660 km away from Mayunmarca, and the later tremor, to the landslide itself. These possibilities suggest that the landslide was not caused by a seismic event. This hypothesis is supported by the appearance of the short-period seismograms from the landslide and recorded at HUA, NNA, and Arequipa (ARE, $\Delta = 581$ km, $AZ = 138^\circ$), which are similar to the records obtained at Pasadena, California, from slumps originating during petroleum drilling opera-

Fig. 1 Location map of the Mayunmarca Valley showing the principal surrounding topographical features (in m) and the area affected by the 25 April 1974, landslide. A-B location of cross section shown in Fig. 2.

Fig. 2 Section A-B of the Mayunmarca Valley (see Fig. 1) showing major geological and topographical features related with the landslide of 25 April 1974. Vertical scale = $2.5 \times$ horizontal scale.

tions near Terminal Islands⁷. However, the possibility has not been eliminated that a small earthquake, whose magnitude was so small that it was not recorded at the local seismic stations, was the triggering source of the landslide. A seismic survey by the Instituto Geofísico del Perú^{5,6} some weeks after the landslide showed the existence of microearthquakes of possible tectonic origin; they had epicentral distances between 2 and 20 km from the recording site, which was located 20 km from the debris dam and at the upstream end of the reservoir and 3 km from the Tablachaca concrete dam (Fig. 1), which serves the Mantaro Hydroelectric Plant. These microearthquakes could have been associated with the presence of the Tablachaca reservoir or the reservoir created by the Mantaro landslide. A special seismic study could be used to determine the origin of this micro-earthquake activity and to determine whether a fault suggested from surface tectonic features and coinciding with the Mayunmarca valley is active or not.

Seismic waves generated by the Mantaro landslide were recorded at several South American observatories as far away as 2,890 km (ref. 8). Short- and long-period seismograms were recorded at HUA, NNA, and ARE. Only long-period signals were recorded at Las Peñas (PNS, $\Delta \sim 900$ km) and at Brasília (BDF, $\Delta = 2,890$ km).

The origin time of the landslide was 0157 22.5 UTC on 26 April 1974 (2057 22.5 LT on 25 April), calculated from P-arrival times on the HUA short-period seismograms and using Herrin's seismological tables⁹. The disturbance recorded on the HUA and NNA short-period seismograms lasted 4 min, while long-period records show higher frequency waves arriving 3 min after the onset.

From the seismic phases originated by the Mantaro landslide (long-period signals shown in Fig. 3), the geological and physiological constitution of the Mayunmarca valley before the event¹, and the vertical distribution of different types of debris in the natural dam², we infer that the landslide was a complex phenomenon composed of different slides which occurred during a period no longer than 4 min but longer than $1\frac{1}{2}$ min. The first slide consisted of unconsolidated soils and sediments underlying the Mayunmarca terrace, nearly $3.5 \times 1.6 \times 0.1$ km (560×10^6 m³). After this original slide, the material in the flanks of the surrounding hills became unstable; therefore, most of the remaining material (around 700×10^6 m³) slid in subsequent secondary slides on the top of the affected area and of the debris belonging to the original slide. Large blocks of rocks on top of the surrounding hills also became unstable and fell; some of this material rolled along the disturbed area and reached the natural dam (7 km away) formed by the previous slides.

A large-amplitude phase arriving 70 s after the onset, which was observed on the HUA and NNA short-period seismograms,

points to the impact of the original slide material on the Mantaro canyon, 3.5 km from the Mayunmarca terrace's middle point. This arrival time suggests an average mass-displacement velocity of 180 km h^{-1} .

The kinetic energy developed during the landslide, using an average slide velocity of 180 km h^{-1} , a material density of 2.7 g cm^{-3} , and a total volume of $1,300 \times 10^6 \text{ m}^3$, was about 4.4×10^{22} erg. Using the same physical dimensions as those of the material involved in the landslide, and the distances shown in Fig. 2, the potential gravitational energy of the Mantaro landslide is of the order of 10^{24} erg.

The energy radiated as seismic energy, E , was calculated from local-station seismograms using the relation¹⁰:

$$\log E = 11.72 + 1.68 M_s \quad (1)$$

The magnitude values, M_s , were calculated from standard equations¹¹.

The values for M_s and E that correspond to the maximum amplitude phases generated by the Mantaro landslide are 3.6 and 6.3×10^{17} erg, respectively, from long-period records, and 3.9 and 18.7×10^{17} erg, respectively, from short-period seismograms.

The M_s value obtained from a BDF long-period seismogram is 4.1, yields an elastic energy of 8.9×10^{17} erg, as computed from the Gutenberg-Richter¹² energy-magnitude relationship. This value is in agreement with the energy values obtained from local-station seismograms.

Fig. 3 Long-period seismograms of the landslide of 25 April 1974 recorded at Huancayo (HUA), Ñaña (NNA), and Arequipa (ARE), showing three seismic phases produced by the landslide. Δ = epicentral distance (km), K , magnification $\times 10^3$, and AZ = azimuth in degrees.

The above results show that seismic energy generated by the 1974 Mantaro landslide was of the order of 10^{18} erg, with a corresponding $M_s = 4.0$. Therefore, the radiated seismic energy is about four orders of magnitude less (0.01%) than the kinetic energy developed during the landslide, which in turn is about two orders of magnitude less (1.0%) than the potential gravitational energy.

The Mantaro landslide is one of the first large landslides to have been widely recorded by several seismic observatories, at local and teleseismic distances. These recordings made calculation of some of the landslide's physical parameters possible. A complete analysis of the seismograms and a detailed interpretation of the landslide mechanism, assessed from such analysis, is in progress.

We thank R. Page, E. Dobrovolny, R. Bucknam, R. Fleming, and J. Healy for critical reviews of the manuscript.

Volcanics from
the Sierra Leone Rise

THE Sierra Leone Rise, located in the east equatorial Atlantic, forms a discontinuous chain of seamounts as shallow as 2 km extending with a general NE–SW trend from near the Sierra Leone coast of Africa, to the St Paul fracture zone near the Mid-Atlantic Ridge (Fig. 1). The origin of this feature has remained a topic of discussion. Sheridan *et al.*¹ have hypothesised that the Sierra Leone Rise is a volcanic structure formed at the beginning of the opening of the Atlantic in the early Cretaceous period. The twin features of the Sierra Leone and the Ceara Rises are probably of oceanic origin and were created 80 Myr ago or later in their present-day position with respect to Africa and South America². The Atlantic ocean exhibits several similar aseismic structures which appear symmetrically oriented with respect to the mid-oceanic ridge, such as the Walvis–Rio Grande Rise and the Iceland Faeroes–Iceland Greenland Ridges. These structures are volcanic edifices having a composition similar to that found in their associated islands^{3–7}. Deep sea drilling of the Ceara Rise^{8,9} penetrated a basaltic basement of the upper Cretaceous period (Maestrichtian) (Leg 39, Site 354). Similarly, a DSDP hole (Leg 41, Site 366) on the Sierra Leone

Rise, penetrated sediments of the same period, without reaching basement¹⁰. We report here the discovery of alkali-rich volcanics in an area of the Sierra Leone Rise. The sediment overlying the rock fragments is aged ~45 Myr.

During the Romancha cruise of the RV Jean Charcot in December 1977 we studied the south eastern slopes of the Sierra Leone Rise, near DSDP Site 366, with the objective of sampling crustal material (Fig. 1). From a detailed bathymetric survey, using a multichannel narrow beam echo-sounder, it was possible to locate the best existing outcrops for dredging. However, despite this, our dredging operation proved unsuccessful, mainly because of the topography of the area surveyed, which consists of gently rolling sediment-covered hills having slopes of <10°.

A sediment core (1.6 m long) was taken in the same area (lat 05°14.9' N; long 20°15.1' W) as the site of the dredging (Fig. 1). This core was recovered from a depth of 2,720 m near the summit of a seamount, which appeared to be the site of important erosional processes resulting from bottom currents (Fig. 2). This core penetrated a sediment veneer and entered a highly altered basement. The upper levels in the core (0–67 cm) are upper Pleistocene to Holocene in age (NN21–N23) with extensive reworked material as old as middle Eocene, especially from 25 to 67 cm. Despite some disparity between the nannofossil and foraminiferal record, only the Oligocene appears absent. From 67 to 110 cm, the ages range from upper to middle

Table 1 Chemical analyses of material collected from a piston core (CH 77-07) from the Sierra Leone Rise

The small clay-like section matrix made up mainly of smectite and zeolite was analysed by X-ray fluorescence (P. Cambon and J. Etou-bleau). The minerals were determined by energy dispersive analysis of X rays.

Eocene (about 45 Myr BP) with some upper and middle Paleocene (60 Myr BP) foraminifera observed. From 110 to 130 cm, the sediment is a foraminiferal chalk epigenised to apatite. The biogenic elements include fish remains and unidentified casts of foraminifera. Below 130 cm no biogenic elements are observed.

The change in mineralogy corresponds to the stratigraphical limits encountered in the core: from 0 to 67 cm depth in the core, the known carbonate fraction comprising about 15% of bulk material consists mainly of kaolinite with some smectite and quartz. At 67–110 cm the smectites forming the main constituents of this level are associated with well-crystallised zeolite of the heulandite type. This latter material is volcanic in origin. Apatite occurs in the lower section of the core at 110 cm. The contact below 130 cm is made up of a thin (<0.3 cm) iron manganese lamina overlying a green brecciated clay-rich material. This material consists mainly of soft green clay aggregates intermixed with reddish brown abundantly altered and highly vesicular rock fragments, and scattered grains of clino-

Fig. 1 Bathymetric map of the Sierra Leone Rise from Uchupi¹⁴ showing the location of the core CH 77-07 and of the Deep Sea Drilling hole 366¹⁰.

pyroxene and feldspar with sharp crystalline boundaries. The small fraction is formed of well-crystallised smectite, and two types of zeolites, heulandite and phillipsite, are also present in smaller amounts. This small clay-like fraction has a mean composition relatively high in silica (41%), and a high total alkali content ($\text{Na}_2\text{O} = 4\%$, $\text{K}_2\text{O} = 2.8\%$) (Table 1), which is compatible with the mineralogy. The relatively high P_2O_5 content (2.0%) reflects the presence of apatite needles.

The type of mineral association (pyroxene, feldspar, apatite, smectite and zeolite) is also encountered in the rock fragments (~3 cm diameter) found within the material recovered. These rock fragments consist of early-formed feldspar set in an altered ferruginous matrix containing pyrite, apatite and tiny laths of parallel oriented feldspar indicating a trachytic textural feature. The feldspars in the rocks are tabular with faint twinning and do not show any signs of secondary replacements. The groundmass is reddish brown due to the extensive alteration, with iron oxide material and smectite being the main alteration minerals encountered. Scanning electron microscope observations show that the zeolites developed *in situ* in geode-like structures. Because of the extended degree of alteration in the groundmass, the chemical analyses of the latter did not give any indication of the nature of the rock. However, microprobe (EDAX) analyses of the unaltered feldspar suggest the alkaline character of the samples.

The composition of the feldspar is indicated in Table 1 and shown on a ternary diagram (or-ab-an) in Fig. 3. The potassic and the sodic ($\text{or}_{1.9} \text{ab}_{56.7} \text{an}_{41.4}$ — $\text{or}_{7.3} \text{ab}_{76.6} \text{an}_{16.1}$) nature of the feldspathic phases differs considerably from that found on the accreting plate boundary of the Mid-Atlantic Ridge (Fig. 3). The molecular percentage of orthoclase in the feldspar from the MAR basalts is insignificant^{11,12} when compared with that of the

Sierra Leone Rise. However, there is a similarity in the composition of the Sierra Leone Rise (Fig. 3) feldspar to the alkaline volcanic series from oceanic islands (such as Hawaii, Saint Helena and Gough islands) (Fig. 3). In addition, the mineral composition and the textural features of the rocks from the Sierra Leone Rise suggest the trachyandesite type of volcanism encountered on the Walvis Ridge⁴. The feldspar analysed from the Walvis Ridge alkali basalt (sample WD 3-4) is also of a potassic nature ($\text{or}_{40} \text{ab}_{45.9} \text{an}_{50.1}$ — $\text{or}_{2.4} \text{ab}_{28.6} \text{an}_{69.0}$) like that from the Sierra Leone Rise (Fig. 3).

In conclusion, both the study of the clay fraction and the rock fragments demonstrate that we have sampled an extremely weathered volcanic outcrop near the top of one of the seamounts of the Sierra Leone Rise. This outcrop is covered by a thin intensely reworked carbonate ooze including Eocene to Palaeocene fauna, overlying a phosphate epigenised foraminiferal chalk of unknown age. This suggests that the last eruptive phase recorded in the sampling area occurred 45 Myr BP, and gave rise to fractionated volcanics of an alkaline nature.

Fig. 2 A profile drawn from a multichannel narrow beam survey chart made in the sampled area located near station CH 77-07 on the Sierra Leone Rise.

Fig. 3 An-or-ab ternary diagram of feldspar composition from various localities. The data from Gough Island¹⁵, from Hawaii¹⁶ and from St Helena¹⁷ we compared with that from the Walvis Ridge and the Sierra Leone Rise. An open circle indicates phenocrysts of analysed feldspar and the filled circles are matrix feldspar found in the corresponding rock samples. The data on the plagioclase from near 37° N in the Atlantic ocean were taken from basalts of the inner floor¹¹ and those from the Rift Mountain Region¹² of the Rift Valley.

We thank the Captain and crew of the RV Jean Charcot for their help and J. Devineau for the sedimentological study done at the Centre des Faibles Radioactivités, Gif-sur-Yvette.

An ophiolite complex of probable early Caledonian age discovered on Karmøy

THE existence, in the Lower Palaeozoic sequence of western Norway, of a major ophiolite complex which is outlined here is shown best on the island of Karmøy, western Norway. Our preliminary interpretation is that the ophiolite complex was thrust into position during the Grampian phase of the Caledonian orogeny, although it has probably been subsequently displaced during the end-Silurian phase of that orogeny.

It is clearly established that the allochthonous Caledonian sequence of western Norway consists of two major complexes, with different tectono-metamorphic evolution, separated by a major stratigraphic unconformity of middle/upper Ordovician age¹⁻³. The older complex shows the more involved tectono-metamorphic history and in many areas was subjected to strong retrogression during the end-Silurian phase of the Caledonian orogeny. The main metamorphism and deformation of this older complex has been correlated with the Grampian deformation in the Scottish and Irish Dalradian^{3,9}. Within the older sequence, thick piles of submarine metabasalts are widely developed. They show pronounced geochemical similarities to ocean-floor basalts, and have been presumed to relate to ridge spreading in a proto-Atlantic ocean⁴⁻⁷. The metabasaltic sequences may be of considerable thickness and in many areas are associated with intrusive cumulate gabbros, trondhjemites and minor developments of serpentinised peridotites. This has given rise to speculations on the possible ophiolitic affinities of the assemblage⁸. However, none of the previously described sequences demonstrate a fully developed ophiolite stratigraphy. Indeed, in many areas, such as the Bergen Arcs^{7,9}, the thick submarine metabasalts and their associated intrusive rocks lie stratigraphically above a considerable thickness of metasediments.

Our recent investigations in the Karmøy region have revealed the presence of a cross section through a major early Caledonian ophiolite complex, which we call the Karmøy Ophiolite. The basal contact of the ophiolite is exposed on the Haugesund peninsula and represents a low angle thrust. On Karmøy the ophiolite sequence is truncated by a major stratigraphic unconformity (Figs 1 and 2) beneath the Skudeneshet Group of middle/upper Ordovician age. The ophiolite contains a tripartite stratigraphy in ascending order as follows.

Zone III: a lowermost plutonic zone comprising layered gabbroic and ultrabasic intrusions together with minor developments of trondhjemites, and cut by later basic dykes. The gabbroic and ultrabasic rocks represent a polyphasic series of intrusions and are in many cases well banded cumulates. Observations of structures in the cumulate sequence show consistent upward younging. These rocks and the associated trondhjemitic intrusions contain evidence of successive phases of high temperature deformation before the emplacement of a major linear steeply inclined dyke swarm of metabasalts and diabases which extends into the overlying submarine metabasaltic pile. This pattern, of pre-dyke deformation is analogous with described occurrences from the Oman ophiolite¹⁰, and the Bay of Islands ophiolite¹¹⁻¹³. At the top of this plutonic zone the dyke swarm becomes a sheeted dyke complex, well exposed at the Airport, and we refer to this as the Lufthavnen sheeted dyke complex. This attains in places 100% dyke rock with only minor disconnected screens of wall rock. These screens are of gabbro in the lower part of the sheeted dyke complex. Screens of gabbro are not found in the upper parts, but gradually it becomes possible, as the sheeted dykes become less dense, to distinguish screens of pillowed metabasalt. In places, however, the contact with the overlying pillow sequence is complicated by later faulting. The dyke swarm observed in the plutonic zone increases in density up towards the true sheeted dyke complex.

Fig. 1 Simplified geological map of Karmøy showing distribution of major units.

Zone II: above this a >2 km thick sequence of greenstones occurs which contains both pillowed and massive flow units of metabasalt, with irregularly developed hyaloclastites. The rocks within this zone show varying intensities of deformation, ultimately producing greenschists from the basalts, although where way-up structures have been observed they show consistent younging away from the lower plutonic zone III. In the upper part of the metabasalt column, horizons of greenschists, which may represent volcanoclastic materials, and irregular jasper layers and bedded cherts are intercalated with metabasalts. Dyke rocks similar to those observed in zone III also cut the metabasalt sequence, but diminish in intensity upwards. Several examples have been observed where such dykes feed individual flow units, and we conclude that the dyke swarm represents the feeders to the lava pile.

Zone I: overlying the metabasalts of zone II, and preserved in a large secondary synform, there occurs a sequence, several hundred metres thick, consisting of ribbon cherts, bedded jasperites, black schists, greenschists which may be of volcanoclastic origin, minor calcareous horizons and in the lower part, thin flow units of pillowed basalts. The main schistosity is related to upright F_1 folds with subhorizontal northwesterly trending axis and an associated steeply dipping northwesterly

Fig. 2 Idealised profile illustrating the relationships of the Karmøy Ophiolite; the rocks of the Skudeneshet Group, though folded, are drawn horizontal. In zone III, nos 1-4 indicate the polyphasic nature of the plutonic assemblage.

trending axial planar schistosity. The rocks of zone I are considered to represent a series of pelagic sediments.

We consider that the zonal sequence I-III described above represents, respectively, layers 1, 2 and 3 of a typical cross-section through oceanic crust. Massive sulphide deposits (Cu, Ni) occur on Karmøy and the neighbouring small islands, though as yet no podiform chromites have been observed in the serpentinised peridotites.

It is not possible, at this stage to provide a precise age for the thrusting (obduction) of the Karmøy Ophiolite on to the Baltic Shield, although by analogy with other Caledonian ophiolite complexes in the North Atlantic region, that is, the Girvan¹⁴ and Newfoundland complexes¹⁴, it may be of lower Ordovician age. The Karmøy Ophiolite, having been both deformed and metamorphosed in greenschist facies, was then intruded by the rocks of the West Karmøy Igneous Complex¹⁵. This latter is a late syntectonic complex of granitic and dioritic rocks with at least five major phases of intrusion. Preliminary Rb/Sr whole rock isochron studies indicate that late granodioritic dykes have an age of ~450 Myr ($\lambda^{87}\text{Rb} = 1.39 \times 10^{-11} \text{ yr}^{-1}$) with an initial $^{87}\text{Sr}/^{86}\text{Sr}$ of 0.7210. The obduction of the Karmøy Ophiolite, on to the Baltic Shield, is considered to have occurred before the emplacement of the West Karmøy Igneous Complex, and thus, the date obtained for the granodioritic dykes provides a minimum age for ophiolite obduction. The presence of highly assimilated gneiss xenoliths in some of the granitic rocks, and the high initial $^{87}\text{Sr}/^{86}\text{Sr}$ ratio of the granodioritic dykes, implies a continental crustal source for the West Karmøy Igneous Complex, beneath the ophiolite. It is thus speculated that the granitic and dioritic magmas originated through partial melting in the downgoing continental plate of Baltic Shield crystallines, perhaps in relation to the active translation of the ophiolite slab.

The source of chert for aboriginal artefacts in southwestern Australia

ABORIGINAL chert artefacts abound in surface assemblages along the western margin of southwestern Australia north of Perth, but no local source of chert is known. The decrease in proportion of chert in assemblages further from the coast has been used as evidence of a westerly source on the present continental shelf but no data have been provided to show that this source is practical. Recent drilling by oil companies offshore in the northern Perth Basin has now shown that chert occurs at depths within reach of the last glacial sea level low and that the postulated source is not only reasonable but highly probable.

Chert is favoured over other materials because of its hardness, and conchoidal fracture which make working of edges and

Fig. 1 Occurrence of Eocene chert artefacts (cross hatched area) in relation to the Precambrian Shield area (crosses) in southwestern Australia.

points simple, and because the products are durable. Several recent papers¹⁻⁶ have discussed the distribution of the artefacts including the aspect of source because no similar chert is known in outcrop in the Perth Basin. Glover and Cockbain¹ showed that the chert is of Middle and/or Late Eocene age on the basis of the characteristic benthic foraminiferid *Mastinella chapmani* Glaessner and Wade.

Chert, identical to that found north of Perth, occurs as artefacts in sediment dated at 12,000–17,000 yr BP from the excavations at Devils Lair on the southwestern tip of Western Australia² and more recently³, chert as recent as perhaps 4,500 yr BP has been discovered at Walyunga, close to Perth. The former age in particular corresponds closely with the last glacially induced sea level low estimated at about 105 m below modern sea level⁷, after allowing for hydroisostatic depression of the continental margin. New data have become available from examination of sediments from four wells offshore in the Perth Basin (Fig. 1)—Challenger No. 1 (WAPET, 1975)⁸, Rottneest Island Bore (W.A. Govt. 1913)⁹, South Turtle Dove No. 1 (WAPET, 1975) and particularly Gun Island No. 1 (BP-1968)⁹—whose Cainozoic stratigraphic sections are shown on Fig. 2. Challenger No. 1 and Gun Island No. 1 both contain Late Eocene sections of cherty limestone of P15/P16^{10,11} age sediments, that from Gun Island also containing *Mastinella chapmani*. Rottneest Island Bore contains a Middle Eocene section^{8,12,13} without chert but South Turtle Dove has Middle Eocene limestone with chert equivalent in age to sediments in the Rottneest Island Bore. The Middle Eocene sediments in the Rottneest Island Bore and South Turtle Dove No. 1 represent deposition during a Middle Eocene interval of high sea level, a

different transgression from the Late Eocene¹⁰ sea level high indicated by the sediments in the other two wells and elsewhere⁸. Thus the most likely source of artefacts, if outcrop occurred, would be the Late Eocene unit, although Middle Eocene cherty limestone cannot be ruled out as an additional source.

The most significant section is that encountered in Gun Island No. 1. The uppermost sample⁹ recovered from this well was a core (Core No. 1) which contains an excellently preserved fauna of Late Eocene planktonic foraminiferids, including *Globigerinatheka index index* (Finlay), *Globorotalia cerroazulensis* (Cole), *Globigerina tapuiensis* Blow and Banner, *G. gortanii praeturritina* Blow and Banner, *G. utilitindex* Jenkins and Orr, and *Pseudoglobobulina primitiva* (Finlay) which indicate a Late Eocene age (P15/P16)¹¹. This material was originally identified as Late Miocene in age⁹. It occurs at 131 m below sea level and probably extends higher. The base of the Late Eocene section is at 228 or 252 m below sea level, the doubt hinging on the age of two undated samples at 246 and 252 m below sea level. Somewhere above the Eocene section is some Miocene,

Fig. 2 Perth Basin sections with Middle-Late Eocene rocks.

required to explain the presence of *Lepidocyclina* in cutting samples from deeper in the well.

In consequence of the discovery of Middle-Late Eocene cherty sediments in several localities west of the present coastline, and at depths within reach of known Quaternary sea level depressions, it is clear that outcrops of these sediments occurred on the present inner continental shelf during the last glacial sea level low and that these provided the source of chert for aboriginal man's artefacts. A westerly source is also indicated by the higher proportion of chert in artefact collections taken from near the present coastline, the proportion decreasing eastward². A westerly source has been suggested^{4,8} and the results of drilling Challenger No. 1 reported⁸, but the results from Gun Island No. 1 are much more relevant to the problem and convincing in proving the source. Searching the continental shelf of Australia and elsewhere will reveal other evidence of prehistoric man's presence. As the Eocene is recognised as an epoch whose sediments commonly contain chert¹⁴, it behoves scientists working on passive continental margins, particularly adjacent to areas of low rainfall and runoff, such as southwest Africa, to be aware of the possibility of the outcrop of Eocene chert during

intervals of low sea level, and of finding evidence of prehistoric human habitation on the present shelf during times of low sea level.

I thank Dr M. A. J. Williams for criticism, West Australian Petroleum Pty. Limited (WAPET) for permission to quote the results of South Turtle Dove No. 1 and the Geological Survey of Western Australia for the loan of samples from Gun Island No. 1 and the Rottnest Island bore.

Why do we not perceive photons?

VERY few photons need to be captured by the receptors of the human eye to excite a sensation of light. The number required is certainly no greater than 100 and may be much less^{1,2}. A single rod requires only one photon to signal light³. A question which therefore arises is why do we not see punctate photon absorptions when we look at a very dim patch of light? The retina catches incident photons only sporadically in time, and therefore in space, when a source is very dim. If very few photons are sufficient to detect light, it might be expected that we should see isolated flashes of light, so that a patch of light appears mottled or speckled. Indeed, if a dim object is viewed on the screen of a cascaded image intensifier, so that each quantum caught by the cathode is amplified, we do see quanta as individual flashes or specks on the display phosphor². This apparent contradiction creates a physiological problem ignored in most standard textbooks on vision although the issue has been raised^{4,5}. We report here a possible solution; we have observed point sources of light set up one at a time very rapidly and at random by computer within a square patch on the face of an oscilloscope and find that as the luminance of the point sources is decreased the number of specks seen increases markedly, and that the appearance of motion, due presumably in the first place to the effect of the chance sequences of specks on motion-sensitive neurones, becomes weaker. We propose that at or near the threshold, the number of specks seen increases to infinity so that the specks crowd together to appear uniform and so the motion ceases.

To test this, after becoming adapted to the dark, we viewed the oscilloscope through a neutral density wedge. Although persistence on the oscilloscope phosphor is brief, a collection of points of changing distribution but constant mean number appears continuously in view. This reflects the operation of storage mechanisms in vision which prolong the visibility of each speck. The number of specks visible to the observer provides a measure of the time constants involved. In a dark room the wedge filter was first set so that nothing was visible. Then it was adjusted until the shape of the square patch on the screen was just continuously discernible. At this level of luminance it was also possible to identify correctly dark shapes (a circle, a square or a triangle, each of which was one-quarter the area of the basic

square patch) in front of the screen. The display looked uniform and devoid of motion, although no more than one light point was being displayed on the screen at any instant.

Now a uniform patch was generated filling the area where the point display had been. A switch enabled us to interchange the point and uniform display. At the threshold for shape identification, the uniform patch could not be distinguished from the random point display.

If the luminance of the point display was again increased, mottled blobs were seen moving around sluggishly; no individual points could be resolved. The display then looked quite different from the uniform display at any luminance. A further small increase in luminance changed the appearance of the patch to a very large number of small discrete points each agitatedly jumping about. The transition from mottled blobs to sharp discrete points occurred over a small range of luminance. As the luminance is raised further to very high levels, the number of specks perceived decreases, each speck appears brighter, and movement becomes less agitated.

These changes in number, motion and texture are so dramatic that a naive observer is astonished that nothing about the display has changed except the luminance, over which he has personal control.

In further experiment, points were plotted at random in a rectangular patch, but every few seconds, four points, arranged to form a square, were displayed, each once only, alongside the rectangular patch. The four points were each of the same luminance as those plotted at random within the rectangular patch. As the luminance decreased the isolated four points were visible only sporadically. Sometimes all four might be seen, sometimes none were seen, and sometimes a random subset was seen. The rectangular patch was seen as uniform only if we could never see any one of the four isolated points.

This finding implies that points are additive in their effects at the luminance levels where the patch presents a uniform appearance. Individual points on their own emit too few photons ever to be visible as specks. Persistence of individual points, perceived as specks, therefore does not explain the impression of uniformity: another effect is involved. A clue to this additional effect is provided by close observation of the four isolated points near threshold. Each point, if visible at all, varies on each appearance, in size, from a small spot to a large globule, and in orientation, sometimes being elongated along one axis, sometimes along another.

Pirenne and Denton³ suggested that at the threshold for vision, the number of quanta required for a sensation of light may be the same for detectors which respond to the activity of different groups of receptors. If so, it will be those detectors with a greater catchment network of receptors which will be most likely to respond when the light is least. It is also these same detectors which are most likely to respond to quanta caught from two or more point sources in different places, as they encompass a larger number of receptors. The functional organisation of the retina will seem to change⁶, when, in reality, all that has happened is that certain detectors are now favoured by the circumstance of occasional quantum emission.

Considerable evidence, both psychophysical and neurophysiological, suggests that vision is organised into channels⁷ specialised for size, and, independently, orientation⁸. Our observation of variation in appearance of single points of light near threshold is consistent with the assumption that sometimes one, and sometimes another, of such channels are by chance obtaining a sufficient quantum catch to report on the appearance of a single spot of light. An analogous effect of variable appearance in the orientation of short lines was reported by Andrews⁹. Those channels which report a larger size are, of course, favoured.

The appearance of uniformity both of a uniform surface in clear light and of a surface made of kinetic points appearing at random, seems to be the combined result of two effects. One is a prolongation of the impression made by quanta caught in either case. The other is a consequence of the organisation of the visual

system into detectors arranged to catch larger patterns of light as the number of quanta caught becomes more sparse. It is perhaps fortunate that our visual system has been so designed as to present uniform surfaces to us as uniform at these low photon levels. If this were not so, surfaces would dissolve in the night into collections of scintillating spots, and the shower of photons from the dim night-sky would obscure the perception of the star formations.

An incidental observation was that any of the four individual points in the last experiment could seem to vary in depth, as well as in size and orientation, when observed with both eyes. This effect is presumably due to random stimulation of different disparity detectors at these low light levels.

On feeding on more than one trophic level

IN trying to understand the structure of ecological communities, ecologists usually pay particular attention to the interactions between pairs, or small groups of species¹. Questions about the 'shape' of the food webs within which these species are embedded are much more rarely asked²⁻⁴. For example, what happens when a population feeds at more than one trophic level (omnivory)? In some real food webs there seem to be no omnivores (Fig. 1a)⁵; in others omnivores are common^{6,7} (Fig. 1c)⁸. In this note we attack the problem of omnivory using simple, linear Lotka-Volterra models of food webs⁹, and show that certain patterns are much more likely to persist on an evolutionary time scale than others. We then compare the model predictions with real food webs.

Consider a system of n interacting species described by equations of the form

$$\frac{dX_i}{dt} = X_i \left(b_i + \sum_{j=1}^n a_{ij} X_j \right) \quad (1)$$

where X_i is the population size and b_i the instantaneous rate of growth of the i th species, and a_{ij} is the *per capita* effect of the j th species on the i th species. We used equation (1) to construct model food webs, using as our criterion for realism the notion that ecologically feasible models must be locally stable^{1,3,9}, and that a rapid return to equilibrium enhances stability^{9,10}.

For models with four species and four trophic levels there are eight possible configurations (Fig. 2). These are distinguished by the 'rank of omnivory', which is the number of predator-prey interactions in excess of those in the model with no omnivory, and by the position of these interactions. Matrices, with sign configurations corresponding to these models were analysed

numerically to determine their maximum eigenvalues ($\lambda_{\max}$), their stability [$\text{Real}(\lambda_{\max}) < 0$] and their relative return times to equilibrium, RT , defined by

$$RT \equiv -\frac{1}{\text{Real}(\lambda_{\max})} \quad \lambda_{\max} < 0$$

The elements of the matrices were chosen uniformly at random with 1,000 replications over three sets of parameter limits, labelled 'vertebrate', 'vertebrate/insect', and 'parasitoid', respectively.

(1) Vertebrate: The off-diagonal elements of the matrices are the products of the *per capita* effect of the prey on the predator multiplied by the predator's equilibrium density or the *per capita* effect of the predator on the prey multiplied by the prey's equilibrium density ($a_{ij}X_i^*$). When predators are larger than their prey the effect of the predator on the prey will be much larger than the converse and the predator's density will be smaller than that of its prey. The elements corresponding to the predator's effect on the prey will therefore be of much greater absolute value than the converse; we chose values on the interval of $(-10, 0)$ for the former and $(0, +0.1)$ for the latter for this set of models. (Note that very large, invertebrate predators (such as starfish) and their prey will also fall into this category.)

Fig. 1 Diagrammatic representation of three natural food webs. *a*, Relationships between insects feeding on Pine⁵. *b*, A simplified representation of the interactions between intertidal gastropods, pelecypods and their prey⁶. Interactions accounting for less than 20% of the predator's diet have been omitted; without this simplification omnivory is common in this web. *c*, Part of a simplified insect host-parasitoid web on a single food plant⁸. Omnivory is common in such webs.

(2) Vertebrate/insect: The *per capita* effect of an insect feeding on a tree is very small, the converse very large. For this set of simulations we chose the interval of the effect of trophic level one on two to be (0, +10) and the converse to be (-0.1, 0). The remainder of the interactions were as (1).

(3) Parasitoid: Here, interactions between trophic levels one and two were as in (2). The remainder were chosen to mimic insect host-parasitoid interactions¹¹, in which the equilibrium population sizes of host and parasitoid may be more similar than in (1), and the *per capita* effect of the host on the parasitoid is large (one host frequently gives rise to one parasitoid). The reciprocal interactions were therefore assigned similar magnitudes, on the intervals: parasitoid on host (-1, 0), host on parasitoid (0, +1).

In all the models, the diagonal elements for the heterotrophic species were zero, implying that each species in the chain (except the first) was ultimately limited only by the abundance of food in the preceding trophic level and not, for example, by behavioral conventions^{12,13}. The species at the base of each food chain (plants) were self limited, with coefficients distributed on the interval (-1, 0).

The option of choosing Jacobian entries directly over the more frequent choice of the b_i and the a_{ij} has several advantages. Rates of increase and decrease in the absence of all other species (b_i) are very difficult for us to visualise; the equilibrium populations (X_i^*) and the effects of predators on prey and vice versa (a_{ij}) are much more obvious. Our models necessarily have positive X_i^* , as the Jacobian entries and the a_{ij} have exactly the same signs. Thus we do not need to calculate the X_i^* from the b_i and the a_{ij} , check their positivity and then calculate the Jacobian; the savings in computation are quite considerable.

For the three sets of eight models, the percentage of unstable models and those stable models with return times in excess of 100 are shown in Table 1. Note first that as the rank of omnivory increases, the percentage of unstable models increases, but for the subsets that are stable, the percentage with long return times generally decreases. These effects work in opposition to one another, so that in the real world, feasibility could either increase or decrease with rank. However, for the vertebrate and vertebrate/insect models, very few matrices were stable for rank greater than one. Second, models of rank one differ in their feasibility, depending on how many levels are spanned by the predator. While over 9% of the vertebrate and vertebrate/insect models are stable when the predator feeds on levels one and two, or two and three, less than 4% of the models are

Fig. 2 Theoretical food-chains. *a*, Without omnivores; *b-d*, with one omnivore-link; *e-g*, with two and *h*, with three omnivore links. The species at the base of each food chain (plants, level 1) are self-limiting. These food chains can be modelled using equations of the form specified by equation (1).

Table 1 Stability of 1,000 random food webs of each type, constructed according to the range of parameter values specified in the text

Percentages of unstable models				
Rank of omnivory	Position (species linked)	Vertebrate	Models Vertebrate/insect	Parasitoid
0	—	0	0	0
1	1-3	81	78	40
	2-4	91	91	68
	1-4	96	96	51
2	1-4 & 2-4	98	98	59
	1-3 & 2-4	97	97	74
	1-4 & 1-3	99	99	50
3	1-3, 1-4, & 2-4	100	100	72
Percentages of stable models with return times > 100				
0	—	44	41	42
1	1-3	21	22	19
	2-4	11	13	19
	1-4	47	46	38
2	1-4 & 2-4	—	—	11
	1-3 & 2-4	—	—	13
	1-4 & 1-3	—	—	13
3	1-3, 2-4, 1-4	—	—	13

Percentages are given to the nearest integer.

stable where a predator feeds on levels one and three. In these latter models a high percentage also have long return times. Third and last, although vertebrate and vertebrate/insect webs show almost identical patterns, the parasitoid webs are generally much more stable though their return times are comparable. High ranking omnivory is relatively easily attained in these webs.

Increasing the rank of omnivory in these models also increases connectance with its well known effect on decreasing stability. However, it is important to investigate the precise restrictions on web shape that low connectance implies. We show elsewhere¹⁴ that our results still hold if the effects of increasing omnivory and connectance are changed independently.

Bringing these results together, we predict that webs with large numbers of omnivores (high ranking omnivory) will be rare in the real world, except in insect host-parasitoid systems (or other groups of species with comparable interaction coefficients and equilibrium population sizes). We also predict that it will be extremely rare to find species that feed simultaneously both high and low in a food web.

Using data on 19 food webs from tropical, temperate, aquatic and terrestrial systems accumulated by Cohen¹⁵ we examined 58 food chains with three or more trophic levels. Of these, 24 had no omnivores, 23 omnivory of rank one, and 11 of rank two or

more. At first sight, 11 webs with high-ranking omnivory is more than might be expected on the basis of our models. However, an examination of the 11 webs showed that in three cases the omnivory was associated with gross lumping of categories (invertebrates, insects and zooplankton), and hence is probably an artefact of the data (because species that are otherwise similar but which feed at different trophic levels are grouped together). Consideration of the remaining webs also highlights a more fundamental problem—the difficulty of distinguishing between links in real food webs that significantly depress the populations being fed upon (controlling links, as in the models) from those that do not. Inclusion of the latter inevitably leads to omnivory (and connectance in general³) being overestimated. This may be compensated for in part by discounting links that provide only a small percentage of an omnivore's diet. Thus, omitting links that make up less than 20% of the prey items taken by omnivores in Paine's⁶ study of a very complex intertidal community, yields a simplified web with only one omnivore (Fig. 1b). Similar results are obtained for the other communities studied by Paine¹⁶. Unfortunately, there are no data available which permit us to analyse the remaining food webs with high ranking omnivory in the same way, and we cannot tell what proportion of the omnivorous links in these webs is also important.

These difficulties aside, our other predictions seem to be supported by the data. Thus, of the 23 chains with omnivory of rank one, only one involves a species which feeds on trophic-levels one (plant) and three (animal) (as in Fig. 2d). The remainder feed on consecutive trophic levels, either one and two (Fig. 2b) or two and three (Fig. 2c). This distribution is significantly different from random ($P < 0.01$), and supports our second prediction. [Of the 65 omnivores examined, 30 fed on levels two and three (both animal) and 35 fed on levels one and two, suggesting that dissimilarity in diet alone is not sufficient to explain the rarity of 1–3 links.]

Only one of Cohen's webs involves insects⁵, and it was one of the simplest analysed (Fig. 1a). However, several highly complex insect-parasitoid webs have also been reported^{7,8}, and it is at least encouraging to see very complex webs developing in the real world in exactly those situations which our models predict are feasible. Figure 1c shows an example⁸. Even after making allowance for the fact that some of the links are minor, such webs tend to be more complex than nonparasitoid webs. Facultative hyperparasitism (omnivory) is particularly common in this group of animals^{7,17,18}.

Obviously there are weaknesses and omissions in most of the published data on food webs, and there are reasons other than population dynamics making omnivory difficult. For example, some species must be prevented from feeding at more than one trophic level by the markedly dissimilar types of food found in each, and some of the differences that we have observed between vertebrate and parasitoid webs may arise because of the peculiar mode of nutrition adopted by insect parasitoids. Comparisons between vertebrate and insect webs are also biased by the tendency for vertebrate ecologists to exclude true parasites from consideration. (When a fox eats a rabbit, it also eats the rabbit's parasites.) This is an unfortunate omission, because internal parasites influence the dynamics of their hosts far more than has generally been realised^{19,20}.

Omnivory in the way that we have modelled it can be generated by several different biological processes: by individuals which seek out prey from different trophic levels at one stage in their life history (conventional omnivory); by different age-classes of one species feeding on different foods (or hosts in the case of true parasites (R. M. Anderson, personal communication)) and by individuals consuming prey and its internal parasites 'in the same mouthful'. But irrespective of the mechanism by which they are generated, trophic links must satisfy certain dynamical constraints if the resulting food webs are to persist. Our models suggest that some trophic patterns and combinations of parameter values are much more stable than others. We believe that considerations of this kind may have an important, but neglected role in determining whether

particular species or whole sets of species can coexist in ecological systems, and points the way to a more general understanding of the design of natural food webs.

We thank Roy Anderson and Michael Hassell for comments on the manuscript, Joel Cohen for the use of his collection of food webs and the Computer Center, Texas Tech University, for computational facilities.

Competition among desert perennials

THE accurate description of horizontal patterns of distribution and the determination of the mechanisms resulting in these patterns^{1,2} are primary objectives of plant ecology. Although there have been many studies of horizontal patterns, most investigations have not proceeded beyond the initial stage of detection and analysis of pattern, leaving suggestions of causation untested. Controlled field experiments that test mechanisms which may regulate distributions are rare³. We have designed a controlled field experiment to evaluate the effects of intra- and interspecific interactions affecting two distinct horizontal patterns, thereby providing a test of current plant distribution theory.

We selected a 2.5-hectare area in the Mojave Desert near Lucerne Valley, San Bernardino County, California (34°33' N, 116°53' W). The terrain is level, ensuring even deposition of rainfall, and consists of deep granitic alluvium. The vegetation is co-dominated by *Larrea tridentata* Cav. (Zygophyllaceae) and *Ambrosia dumosa* (Gray) Payne (Asteraceae) with derived species' importance values (based on their relative dominance, relative frequency and relative density in 104 5 m × 5 m random quadrats) of 39.7% and 49.2%, respectively.

Both these species are important components of many desert communities—co-dominating 70 per cent of the Mojave Desert⁴. *Ambrosia* is short, hemispherically shaped and drought-deciduous, whereas *Larrea* is tall, cone-shaped and evergreen. Also, *Larrea* has been shown to be regularly distributed in certain areas of both the Mojave and Sonoran Deserts^{5,6}, where competition for moisture is hypothetically very keen.

To determine the horizontal distribution of these species, we sampled the site and analysed our data in a manner similar to that of Woodell *et al.*⁵. The density of *Larrea* and *Ambrosia* were measured in 250 10 m × 10 m quadrats from a random,

Table 1 Horizontal distribution of shrubs

Species	Mean ($\bar{x}$) (shrubs per 100 m ²)	Variance (σ^2)	$\frac{\sigma^2}{\bar{x}}$	Distribution
<i>Larrea tridentata</i>	3.62	2.06	0.57	Regular
<i>Ambrosia dumosa</i>	19.52	96.56	4.95	Contagious

Both species' distributions are significantly nonrandom at the 0.1% level using Student's *t* test.

stratified sample. Utilising the variance/mean ratio method described by Greig-Smith¹ (significantly >1 = clumped, significantly <1 = regular), we determined the direction and degree of non randomness. The results in Table 1 clearly indicate that the horizontal distribution of *Ambrosia* is clumped and that of *Larrea* is regular. Using Pearson product-moment linear correlations of the density and the total biomass per 5 m $\times$ 5 m quadrat of *Ambrosia* on *Larrea* (which proved insignificant), we concluded that *Larrea* and *Ambrosia* were independently distributed relative to each other⁷.

As all regular and some clumped distributions have been attributed to plant-plant interactions and because the literature suggests the occurrence of competition for moisture in the desert^{2,5,8,9,10}, we decided to investigate these possible distributional control mechanisms using a differential removal experiment in the field. Forty 100²-m circular plots (5.64 m radius) within the 2.5-hectare area were circumscribed using average-sized *Larrea* bushes for centre points and as monitored plants. From these plots four categories (10 replicates each) of control and test plots were randomly chosen. These categories were: (1) control—no plants removed; (2) total removal—all *Larrea* and *Ambrosia* except centre *Larrea* removed; (3) *Larrea* removal—all *Larrea* except centre *Larrea* removed; (4) *Ambrosia* removal—all *Ambrosia* removed. Plants were removed by cutting at ground level. We also set out four equivalent categories of plots in which individuals of *Ambrosia* were similarly utilised as both centre points for circumscribing and for monitoring. On completion of the various treatments, predawn measurements of plant water potential were taken to evaluate the water status of the monitored plants using the Scholander pressure bomb method^{11,12}.

Immediately after a 60-mm rainfall in August, we began to measure water potentials at semi-monthly intervals. Initially the water potentials of *Larrea* were ~ -20 bar and those of *Ambrosia* ~ -2 bar with no consistent differences among treatments. (These are high potentials for both species.) As drying of the soil continued and plant water potentials decreased through time, consistent differences among treatments developed (Table 2). In the *Larrea*-monitored plots the mean water potential of the monitored *Larrea* plants in the control

plots (-39.0 bar) was significantly lower than that of the *Larrea* plants in the total removal (-33.7 bar) and in the *Ambrosia* removal plots (-34.6 bar), but not significantly different from the mean water potential of the monitored plants in the *Larrea* removal plots (-39.3 bar). Similar results were obtained in the *Ambrosia*-monitored plots. The mean water potential of the monitored *Ambrosia* plants in the control plots (-44.2 bar) was significantly lower than that in the total removal plots (-30.5 bar) and in the *Larrea* removal plots (-36.5 bar), but not significantly different from the mean water potential of the monitored plants in the *Ambrosia* removal plots (-44.6 bar).

To our knowledge this is the first experimental evaluation of plant competition in deserts. The results of this study suggest that competition for soil moisture does occur at this site when water availability is low and that, with the present horizontal arrangement of individuals, interspecific competition is more intense than intraspecific competition. The actual mechanism(s) responsible for the interspecific effects on plant water potentials is undetermined. While we suspect the mechanism may be a simple depletion of a limiting resource (water) by interacting species, the possibility of allelopathy, especially by the roots, cannot be ruled out.

Furthermore, it must be emphasised that, because of the feedback type of relationship between competition and distribution, the present status of competition at this desert site may not be indicative of the historical interactions among the plants which have resulted in the present distributions. It is possible that at our site *Larrea* plants were once clumped and competed intensely with each other. Through time, such competition may have resulted in the present regular distribution in which few plants are close to each other, and competition is thereby minimised. Alternatively, *Ambrosia* plants may have remained clumped because most of their growth occurs at relatively high water potentials (> -30 bar) when water may not be a limiting resource.

The negative interactions between *Larrea* and *Ambrosia*, indicated by the plant water potentials in this study, are surprising in view of the independent distributions of these species relative to each other. These distributions may be the result of other, overriding, physiological and environmental factors, or the interspecific interactions have not been of sufficient intensity or duration to affect the distributions. The significance of the negative interactions between *Larrea* and *Ambrosia* is yet to be determined in terms of production.

We thank W. H. Schlesinger, C. E. Muller and J. H. Connell for reading the manuscript, and D. Schlesinger for statistical and computational assistance. This work was supported by University of California Patent Fund, Sigma XI, and the Bache Fund of the National Academy of Sciences.

Diverse modes of action of biotic and abiotic phytoalexin elicitors

PHYTOALEXINS are inducibly formed higher plant metabolites that are antibiotic to certain potential plant pathogens¹. At least 75 plant species representing 20 families have been shown to accumulate phytoalexins in response to infection¹⁻³. Phytoalexins also accumulate in plants in response to various agents termed elicitors¹, including substances of pathogen origin (biotic elicitors) and abiotic elicitors such as heavy metal salts and detergents¹⁻³. Elicitors may be useful for investigation of the molecular basis of phytoalexin production or disease resistance expression¹. However, the mechanisms by which such diverse elicitor molecules induce phytoalexin accumulation in plants are unknown. I have found⁴ that levels of glyceollin, a phytoalexin produced by soybean [*Glycine max* (L.) Merr.] hypocotyls in response to infection with the fungal pathogen *Phytophthora megasperma* var. *sojae* A. A. Hildb., are regulated by relative rates of induced biosynthesis and constitutive degrading activity. I report here the effects of various biotic and abiotic elicitors on biosynthesis and degradation of glyceollin in soybean tissues.

Detached cotyledons from 8-d-old seedlings of the soybean cultivar Harosoy 63 were wounded as described by Ayers *et al.*⁵, but wounds were made on the lower surface of the cotyledons. A 80 µl drop of aqueous biotic or abiotic elicitor solution containing rifampicin and ampicillin at 10 and 500 µg ml⁻¹, respectively, was placed on to the wounded areas of 10 cotyledons and these were incubated on moist filter papers in Petri dishes at 25°C. Glyceollin did not accumulate in the control (H₂O-treated) cotyledons (Fig. 1a) despite the fact that significant levels of biosynthetic activity were present ~10 h after wounding (Fig. 1b). Failure of the control cotyledons to accumulate glyceollin seemed to be due to the presence of glyceollin degrading activity (Fig. 1c). Thus there was apparently a balance between synthesis and degradation, such that glyceollin did not accumulate. It would therefore be expected that glyceollin accumulation could be elicited by treatments that either inhibited its degradation and/or enhanced its synthesis to exceed the rate of degradation.

Treatment of the cotyledons with a biotic elicitor such as cell walls of *Phytophthora megasperma* var. *sojae*, a fungus highly pathogenic to certain cultivars of soybean¹, greatly stimulated the glyceollin biosynthetic activity of cotyledons (Fig. 1b) and resulted in considerable accumulation (Fig. 1a). The biotic elicitor, however, had no significant effect on glyceollin degrading activity (Fig. 1c). In contrast, an abiotic elicitor such as HgCl₂ also elicited glyceollin accumulation (Fig. 1a), but strongly inhibited glyceollin degrading activity of the cotyledons (Fig. 1c) with only slight effects on biosynthetic activity (Fig. 1b). These results show that the primary mechanisms of action of the biotic and abiotic elicitors are distinctly different.

All the effective abiotic elicitors of glyceollin accumulation tested, including various metals and detergents, strongly inhibited glyceollin degrading activity but their effects on synthetic activity were relatively small (Table 1). Some abiotic elicitors such as CuSO₄ and K₂Cr₂O₇ partially inhibited synthetic activity and glyceollin accumulation in response to these abiotic elicitors was reduced relative to those that did not inhibit synthetic activity (Table 1). High concentrations (10 mM) of some abiotic elicitors such as HgCl₂ and CdCl₂ did not induce glyceollin accumulation, possibly because of their high toxicity to plant cells at these concentrations as indicated by strong inhibitory effects on synthetic activity. Chemicals such as CoCl₂ and CrCl₃ that inhibited synthetic activity more strongly than degrading activity or those such as CsCl, SnCl₄ and low concentrations (0.1 mM) of HgCl₂ and CdCl₂, that had no significant effect on either synthetic or degrading activity were also inactive as elicitors of glyceollin accumulation. Thus, only those chemicals that selectively inhibited glyceollin degrading activity but not its synthetic activity were active abiotic elicitors.

In contrast to abiotic elicitors, none of the tested biotic elicitors of fungus origin inhibited glyceollin degrading activity, but all stimulated its synthetic activity to ~seven to eight times that in the control cotyledons (Table 1). Stimulation of the synthetic activity seemed to be caused only by biotic substances with elicitor activity, since soybean cell walls or any of the other biotic substances listed in Table 1 did not significantly affect glyceollin synthesis or accumulation. Thus the probable mechanism of action of biotic elicitors is stimulation of glyceollin synthesis to rates exceeding its rate of degradation.

Although the mechanisms underlying accumulation of phytoalexins by biotic elicitors are not understood¹, my earlier observations^{4,6-8} indicate that glyceollin accumulation in response to inoculation of soybeans with incompatible races of *Phytophthora megasperma* var. *sojae* may be due to increased biosynthesis resulting from *de novo* transcription of DNA. The present study indicates that such enhanced *de novo* biosynthesis may also occur in soybean after treatment with biotic elicitors, but not abiotic elicitors. The initial 'recognition' of fungal biotic elicitors by soybean cells is being studied in several laboratories^{1,5,9,10}.

The unique response of soybean cotyledons to abiotic elicitors is significant because it offers insight into the frequently observed accumulation of plant phytoalexins in response to 'stress', that is a change in the normal physiological state of the plant cell environment. The present data clearly indicate that phytoalexin accumulation can occur in response to mechanical wounding of plant tissue in conjunction with inhibition of the normal, apparently constitutive phytoalexin degrading system.

The lack of specificity of the phytoalexin response to various abiotic elicitors has been used as an argument against a role of phytoalexins in disease resistance¹. My results, however, suggest that this nonspecific phytoalexin response should be dis-

Fig. 1 Effects of ○, a biotic elicitor [Fungal cell wall (FCW), 50 µg ml⁻¹] and ●, an abiotic elicitor [HgCl₂, 1.5 mM] on accumulation (a), synthesis (b) and degradation (c) of glyceollin in soybean cotyledons. For measurement of glyceollin accumulation, the wound droplets on the elicitor-treated cotyledons were collected by elution with water at various times after incubation, and glyceollin was extracted by ethylacetate⁵ and quantitated by a TLC/UV method⁶. For estimation of glyceollin biosynthetic activity in the elicitor-treated cotyledons, each wound droplet was replaced by 10 µl of ¹⁴C-L-phenylalanine solution (15 µCi ml⁻¹, 522 mCi mmol⁻¹) at various times after incubation as indicated on the abscissa and the isotope was fed for subsequent 1 h. The wounded sides (~1 mm thick) of 10 cotyledons were then collected immediately and rates of ¹⁴C incorporation into glyceollin were determined by modifications of the TLC/UV method⁶ as described elsewhere⁴. For measurement of glyceollin degrading activity, eight freshly-collected cotyledons were sliced into halves parallel to their upper and lower surfaces and incubated in 50 ml flasks containing 10 ml of water, 300 µg of purified glyceollin, antibiotics as above, and a biotic or abiotic elicitor at the indicated concentrations. The flasks were shaken at 60 strokes per min at 25°C for various times and glyceollin remaining undegraded in the flasks was extracted by homogenisation with 20 ml of ethanol and quantitated⁶. FCW was prepared from *Phytophthora megasperma* var. *sojae* grown in a soybean hypocotyl medium⁶ for 5 d by the method of Ayers *et al.*⁹ but fungal homogenate was prepared by pulverising mycelium under liquid N₂ in a mortar and suspending in 0.5 M potassium phosphate (pH 7.2) followed by a brief sonication (1 min, 5 times). The concentration of the biotic elicitor is based on glucose equivalent by anthrone assay. ▲, Controls (water only).

Table 1 Effects of biotic and abiotic elicitors on accumulation, synthesis, and degradation of glyceollin in soybean cotyledons

Elicitor	Elicitor concentration	Accumulation (μg)	Glyceollin synthesis (% of control)	Degradation (% of control)
H ₂ O (control)	—	<20	100 (3,400–4,200 c.p.m.)*	100 (220–245 μg)*
<i>Effective abiotic elicitors</i>				
HgCl ₂	1.5 mM	972 $\pm$ 202	110 $\pm$ 34	28 $\pm$ 8
CdCl ₂	1.0 mM	932 $\pm$ 219	138	48
AgNO ₃	3.3 mM	1,280 $\pm$ 274	202 $\pm$ 56	19 $\pm$ 10
CuSO ₄	10.0 mM	472 $\pm$ 125	35	17
K ₂ Cr ₂ O ₇	3.3 mM	495 $\pm$ 194	42	29
Triton X-100	5.0 mg ml ⁻¹	1,391 $\pm$ 320	105 $\pm$ 10	28 $\pm$ 6
Nonidet P-40	5.0 mg ml ⁻¹	1,205 $\pm$ 295	98 $\pm$ 5	25
<i>Ineffective abiotic elicitors</i>				
HgCl ₂	0.1 mM	<20	119	92
	10.0 mM	<20	6	11
CdCl ₂	0.1 mM	<50	105	97
	10.0 mM	<100	9	28
CoCl ₂ †	10.0 mM	<100	28	55
CrCl ₃ †	10.0 mM	<20	18	48
CsCl†	10.0 mM	<30	139	97
SnCl ₄ †	10.0 mM	<20	113	104
<i>Effective biotic elicitors</i>				
Fungal extracellular metabolite	5.0 μg ml ⁻¹	1,352 $\pm$ 281	691 $\pm$ 181	102 $\pm$ 2
	20.0 μg ml ⁻¹	1,605 $\pm$ 309	831 $\pm$ 274	103 $\pm$ 5
Fungal cell wall	50.0 μg ml ⁻¹	1,295 $\pm$ 382	756 $\pm$ 126	97 $\pm$ 5
	250.0 μg ml ⁻¹	1,895 $\pm$ 225	856 $\pm$ 205	101 $\pm$ 4
Fungal cytoplasmic supernatant	100.0 μg ml ⁻¹	1,025 $\pm$ 125	721	95
	500.0 μg ml ⁻¹	1,434 $\pm$ 194	777	93
<i>Ineffective biotic elicitors</i>				
Fungal culture medium control†	5.0 μg ml ⁻¹	<20	132	97
Soybean cell wall†	200.0 μg ml ⁻¹	<20	115	105
Soybean cytoplasmic supernatant†	200.0 μg ml ⁻¹	<20	142	98

Amounts of glyceollin accumulated and degraded were measured at 24 and 8 h, respectively, and rates of synthesis at 18 h after incubation of cotyledons with elicitors, as described in Fig. 1. For preparation of fungal extracellular metabolite, *Phytophthora megasperma* var. *sojae* was cultured as described in Fig. 1. After fungal mycelium was removed by filtration, the culture fluids were lyophilised, dissolved in 10 mM Tris-HCl (pH 7.2), and passed through a column of Sephadex G-50 equilibrated with the same buffer. Fractions eluted in the column void volume were used. Fungal cytoplasmic supernatant was prepared by centrifuging a mycelial homogenate of the same fungus in 10 mM Tris-HCl (pH 7.2) at 80,000 g for 30 min and by dialysing the resulting supernatant against the same buffer. Fungal culture medium control was the fraction corresponding to the fungal extracellular metabolite fraction but the medium was not inoculated with the fungus. Soybean cell wall and cytoplasmic supernatant were prepared using the same methods described for preparation from the fungus. Means and standard errors are indicated where 3 to 5 replicate experiments were run, and other values are means of two replicate experiments.

* Actual values of incorporation of ¹⁴C-phenylalanine into glyceollin (c.p.m.) or of amounts of glyceollin degraded (μg) in the control cotyledons.

† Abiotic chemicals or biotic substances which did not induce glyceollin accumulation at all concentrations tested (0.033–20 mM for abiotic chemicals and 5–1,000 μg ml⁻¹ for biotic substances). Concentrations of effective abiotic elicitors were those approximately optimum in inducing glyceollin accumulation. Concentrations of all biotic substances were based on glucose equivalents measured by anthrone assay.

tinguished from the specific response associated with disease resistance, as it seems that the fungal metabolites operate differently from the abiotic elicitors.

The results presented here suggest that it may be possible to discover a new type of plant protectant, protecting against infection not through intrinsic antibiotic activity, but through an effect on plant-pathogen interaction resulting in higher accumulation of phytoalexins.

The blind octopus, *Cirrothauma*

THE rare deep-sea octopod *Cirrothauma murrayi* Chun 1910 was first described from a single specimen caught during the Michael Sars Expedition of 1910 (ref. 1). Until now it has been caught only four more times². We describe here three specimens of this species that were recently caught during biological cruises of the RRS Discovery (Fig. 1). All of these animals, including the Discovery ones, have been caught at depths of more than 1,500 m, except one that was dip-netted through the ice of the Arctic Ocean³.

Cirrothauma belongs to a poorly known family, the Cirroteuthidae, which have cirri along the arms, a pair of fins, a deep interbranchial web and no radula¹. *Cirrothauma* is reddish-brown semi-transparent and gelatinous in consistency (Fig. 1). Photographs of other cirroteuthids taken with deep-sea cameras have shown them swimming close to the bottom and looking like medusae, with head down and arms and web widely extended^{4,5}. In other photographs they are swimming backwards with a more typical cephalopod posture⁵.

The eyes are remarkable, being simple open cups, with no trace of lens, iris or ciliary body (Fig. 2). The cup is closed by a transparent continuation of the sclera and covered by a thin gelatinous layer less than 1 mm thick. The eyes were only 3 mm in diameter in Chun's animal, the mantle length being 40 mm. Our specimens are larger (155 mm (A), 130 mm (B) and 220 mm (C) mantle length) with an oval pupil 9 mm $\times$ 12 mm in the smallest (Fig. 2). The retinæ are better developed than is implied from Chun's description¹ (Fig. 3a). However, the rhabdoms are not regularly packed as they are in *Octopus*, and there is no limiting membrane covering their outer ends, which therefore turn and taper irregularly. In one of the Discovery specimens part of the retina was folded, to make a series of chambers, lined by separate, single rhabdoms, looking, as Chun put it, "like little flames"¹ (Fig. 3b). The retina of specimen B therefore seems to be in a degenerating condition similar to that of some deep-sea fishes⁶.

The optic nerves are very long and pass through a large mass of tissue, the 'white body', to a minute optic lobe (Fig. 2). The structure of this is very simple, it lacks the peripheral layers of small cells that are characteristic of cephalopods with good vision. The vertical lobe and other parts of the visual memory system, so well-developed in *Octopus vulgaris*⁷, are reduced. It is difficult to understand what use may be made by the animal of a photoreceptor system such as this, with neither lens nor pin-hole aperture. That the animal has some use for photoreceptors is shown by the fact that the epistellar bodies, photosensitive vesicles near the stellate ganglion, are especially large in *Cirrothauma*.

There are large sac-like statocysts, suspended by muscles at some distance from the brain. As in other octopods there are inner and outer sacs separated by a perilymph (Fig. 4). The maculae are long oval patches with small circular statoliths not covering the whole area. There are no maculae neglectae. The

Fig. 1 *Cirrothauma murrayi* Chun 1910 photographed on board RRS Discovery while still just alive. The posterior end of the mantle is translucent and parts of the fins are transparent. Marks from the nets can be seen on the skin. One eye is visible at the side of the long, slender funnel. The arms are united by the web along most of their length. The stalked 'suckers' lie towards the tips of the arms. Specimen B caught at 3,000–3,500 m, mantle length 130 mm, funnel length 61 mm.

Fig. 2 The central nervous system, one eye, the statocysts and the buccal mass after dissection. The black rostral tip of the lower beak projects beyond the lips. The oesophagus is heavily pigmented and can be seen just behind the brain. Specimen B.

crista runs round the circumference of the sac, constricting it somewhat by a waist to form lateral and medial parts. There is a single anticrista, as in other octopods. The large volume of endolymph is presumably related to the need for the crista to detect slow angular rotations. This condition resembles that found in *Vampyroteuthis*, but the latter has several anticristae, as in decapods⁸.

The cirri are characteristic of the Cirroteuthidae and are absent from all other cephalopods with the exception of *Vampyroteuthis*. *Cirrothauma* has a longitudinal row of cirri on either side of the single row of suckers. Though not shown in Fig. 1, they can probably extend to a considerable length and are presumably tactile organs. They were stretched outwards and away from the arms in the cirroteuthids photographed in the sea⁵. Sections of the Discovery specimens show that the tactile centres of the brain are well-developed, unlike the visual system, and perhaps the cirri provide the main source of information about the surrounding conditions and for the detection of food. There are 38 suckers along each arm of our specimen of 155 mm mantle length (A) and 36 on the Chun (or 'type') specimen¹. Chun recognised two distinct sets of suckers, one being unique amongst cephalopods¹. He described the latter as 'tiny suckers situated on long, plump, spindle-shaped gelatinous stalks... 4–5 mm long in the middle of the arms and gradually become shorter towards the tips and proximally'. He suggested that they had lost their function as there was no opening. That they are suckers, even though they do not have an orifice, is shown in histological sections by the presence of a cuticle very similar to that found covering the infundibular surface of the suckers of *Octopus vulgaris* and other octopods⁹. In view of the presence of this sucker cuticle, it seems unlikely that Chun's¹ reserved interpretation that there were 'certain similarities with luminous organs' can now be upheld. Dr P. J. Herring (Institute of Oceanic Sciences) has also looked at the sections for us and can find no trace of light organs. The second type of sucker does have an opening and these suckers lie near the mouth, being the first six in both Chun's animal and in specimen A. The opening of the sucker is restricted and does not lead to a suction chamber such as is usually found in octopods⁹. There is a very shallow cup with radial muscles and a typical cuticle which, like that in other octopods, can be shed as a disk⁹.

The buccal mass is large as is the rostrum of the lower beak, which projects beyond the lips (Fig. 2). As in other cirroteuthids the radula is absent^{1,10}, in its place there is a fleshy tongue-like

Fig. 3 *a*, Section of the retina of specimen C. *b*, Isolated rhabdoms from a sac formed by folding of the retina of specimen B.

structure attached ventrally along most of its length. At the front of this 'tongue' there is a large papilla, perhaps the salivary papilla.

The funnel is extremely long and slender¹, being 47, 61 and 185 mm in animals A, B and C, respectively (Fig. 1). The mantle opening is small and closely surrounds the base of the funnel. The function of this long funnel is not known but it could be important in directing fine jets of water during delicate manoeuvring movements while swimming upside down in the

Fig. 4 Left statocyst from specimen A seen from in front. The statolith is displaced and seen edge on near to the macula. D, dorsal; L, lateral.

medusoid form. Perhaps its jets of water are used to stir up the sediment on the seabed to expose small prey, or possibly to bury the eggs in soft sediment.

The cirroteuthids differ from all other octopods and resemble decapods in the presence of fins (Fig. 1). These, like the cirri, recall the condition in *Vampyroteuthis*¹¹. It seems probable that these deep-sea animals still retain characteristics common to both octopods and decapods. In this connection it is interesting that *Cirrothauma* and another cirroteuthid of which we also have sections, both have a system of giant nerve fibres¹¹, which are usually only associated with decapods¹². We hope that further study of the Discovery specimens may help to settle several problems of structure, function and mode of life of these curious animals.

We thank Miss P. R. Stephens for assistance.

Spike frequency adaptation in amphibian sensory fibres is probably due to slow K channels

SPIKE frequency adaptation (SFA)—a decrease in firing frequency during the action of a maintained stimulus—is a mechanism for the input-output transformation of a signal and it is common at many levels of the animal kingdom. The occurrence of SFA in amphibian sensory nerves¹⁻⁴ offers an opportunity to explain the phenomenon at the membrane level in terms of the Hodgkin-Huxley (HH) theory⁵. Here we show that SFA in amphibian nerve is probably due to a current through slow K channels, and we suggest that these channels must also be responsible for different cases of SFA in nerve cells of various types.

The HH model for the node^{1,6} gives, for constant current steps, rhythmic firing but not SFA⁷. Further mechanisms with relatively long time constants are obviously needed to account for SFA. As SFA lasts only from several ms to a few tens of ms it is evident that slow Na (ref. 8) and fast K (ref. 9) inactivations, with time constants of several hundred ms and even 1 s, cannot be a source for SFA. Electrogenic pumping is also excluded (for refs and discussion see ref. 10). K⁺ accumulation near the node¹¹ can be expected, by analogy with squid axon¹², not only to fail to cause SFA but also to give inappropriate changes of successive overshoot and undershoot amplitudes in a train, decreases rather than increases. Therefore, we consider that the necessary mechanism involves the currents flowing through the slow K channels. The addition of slow K channels with the properties we have measured gives calculated SFA with most of the properties measured by others. Also, there are indications of slow K channels in amphibia in which SFA is usually observed, *Xenopus*

laevis^{2,4,13}, *Rana esculenta*^{3,4,14} and *R. ridibunda*^{4,15,16}. In the case of *R. ridibunda* many characteristics of the channels have been determined¹⁶, and they are used here for SFA calculations. We modified the HH model to present the overall K current (I_K) of the node as the sum of two components: a fast (I_{K1}) and a slow (I_{K2}) component.

The fast channel in *R. ridibunda* seems to behave like the familiar K channel in *R. pipiens*^{1,17}. The two channels were attributed to sensory nerve on the basis of their corresponding $n_{1\infty} - E$ and $n_{2\infty} - E$ curves on the E (membrane potential) axis, as had been done for *R. esculenta*¹⁸. I_{K1} can thus be presented by the HH-Dodge model for *R. pipiens*¹. I_{K2} can also be presented by an HH-type model, but differing in behaviour with E of the HH variable n_{II} describing the E -dependent gating kinetics of the slow K channel (ref. 16 and Fig. 1):

$$I_{K2} = g_{K2}(E - E_{K2}) \quad (1)$$

$$g_{K2} = \bar{g}_{K2} n_{II}^4 \quad (2)$$

where g_{K2} , $\bar{g}_{K2}$ are, respectively, the slow K channel conductance and its maximum value; E_{K2} is the K equilibrium potential for I_{K2} .

In *R. ridibunda* the ratio $\bar{g}_{K2}/\bar{g}_{K1}$ is usually 0.2–0.8, depending on the frog specimen¹⁶. E_{K2} is unknown. It was taken to be equal to E_{K1} , that is, E_K in *R. pipiens* (–75 mV). The variable n_{II} can be represented fully by two functions: the steady-state relationship $n_{II\infty} - E$ and its kinetic characteristic $\tau_{nII} - E$. Both are given in Fig. 1.

For computations of spike trains, Hille's version of the HH-Dodge model¹⁷ was used. Small variations of maximum Na conductance with E (the term $(1 - E/183)$) were neglected so that we could follow quantitatively the critical firing level in terms of the theoretical relationship between firing potential and parameters entering the HH model¹⁹. To induce rhythmic activity the $h_{\infty} - E$ curve was shifted by 15 mV in the depolarising direction. Computations were carried out on a BESM-6 computer (Russian index) with a Fortran program.

Figure 2 shows the computed firing behaviour for the case when the contribution of I_{K2} into the overall I_K was varied by variation of $\bar{g}_{K2}$, that is, the density of the slow K channels. At $\bar{g}_{K2} = 0$ the firing is purely rhythmic (Fig. 2a). However, SFA is well expressed even with $\bar{g}_{K2}$ as small as 10% of $\bar{g}_{K1}$ (Fig. 2b), and quickly increases with $\bar{g}_{K2}$ (Fig. 2c,d) until damping of repetitive responses is complete (Fig. 2e).

Although Fig. 2 shows the simplest case, when an increase in I_{K2} (a–e) is due to $\bar{g}_{K2}$, it probably qualitatively covers most of the previously described basic features of SFA in amphibian nerve^{1–4}. One of them is a progressive rise in time of the overshoot and undershoot (for spikes following the first) amplitudes with nearly constant firing level. This is clearly seen in Fig. 2c and d. Further, the spike trains in amphibian nerves are finite, and this can be seen in Fig. 2d where, with sufficient density of slow K channels (that is, with sufficiently large $\bar{g}_{K2}$), only one spike can be produced (Fig. 2e), which may be considered an extreme case of adaptation.

Thus, even the simplest model considered can account not only for SFA as such (a decrease in firing frequency with time) but also for accompanying phenomena (the character of changes of the overshoot and undershoot amplitudes and finite spike trains). Also any variation of parameters in equations (1) and (2) leading to greater I_{K2} will lead to more pronounced SFA. This provides a variety of conditions for critical damping, as is the case in actual experiments (compare records of spike trains in refs 1–4). A proper choice of the starting value h_0 (refs 4, 7) and consideration of Na^+ accumulation near the inner surface of the nodal membrane¹⁰ and K^+ accumulation near its outer surface¹¹, would make the agreement between theory and experiment even better. There is, however, little hope of obtaining full details of SFA for a particular node, because this requires knowledge of the HH picture of all the currents involved and of the accompanying processes (such as Na^+ and K^+ accumulation, see above) on the same node. We aimed to show that the slow K channels are responsible for SFA in the node, and that this SFA

can be modified further by the various factors discussed here. The construction of models seems to be the best way to study basic features of SFA, so as to adjust relevant HH parameters and those of accompanying processes to fit experimental SFA or to look for interesting phenomena which can then be sought in an experiment. Our results indicate that slow K channels are responsible for SFA in amphibian nerve. In other amphibian

Fig. 1 a, Function $n_{II\infty}(E)$ for slow K channel used to compute the sensory nerve firing behaviour in Fig. 2. $\circ$, $n_{II\infty}$ values obtained by fitting $I_K - t$ curves associated with depolarising E steps from various values of E_1 (given by abscissa) to $E_2 = 50$ mV by searching with least squares the parameters of the equation for overall I_K :

$$I_K(t) = g_{K1}(t)(E - E_{K1}) + g_{K2}(t)(E - E_{K2})$$

where I and II refer to fast and slow K channels, respectively. I_{K2} was measured in 128 mM KCl and 3×10^{-4} mM tetrodotoxin, with leakage current subtracted. As $E_{K1} = E_{K2}$, $n_{II\infty}(50 \text{ mV}) = n_{I\infty}(50 \text{ mV}) = 1$, and there is no K^+ accumulation near the node in this solution¹⁶, the equation acquires the HH form:

$$g_K(t) = \bar{g}_{K1} \cdot \left[1 - (1 - n_{I\infty}(E_1)) \exp\left(-\frac{t}{\tau_{nI}}\right) \right]^{x_1}$$

$$\bar{g}_{K2} \cdot \left[1 - (1 - n_{II\infty}(E_1)) \exp\left(-\frac{t}{\tau_{nII}}\right) \right]^{x_{II}}$$

The terms: $\bar{g}_{K1}$, $n_{I\infty}(E_1)$, τ_{nI} , x_1 , $\bar{g}_{K2}$ (where $\bar{g}_{K2} = (1 - \bar{g}_{K1})$), $n_{II\infty}(E_1)$, τ_{nII} , x_{II} in the latter equation were given values so that they fitted the whole family of experimental $I_K - t$ curves (now assumed to be the shape of the $g_K - t$ curves) associated with a set of E_1 . Parameters for channel I happened to be the same as for the K channel in *R. pipiens*^{1,17}. x_{II} was found to be 4 (as x_1), $n_{II\infty}(E_1)$ ($\circ$), τ_{nII} ($\bullet$) in b. Details of the fitting procedure are given elsewhere¹⁶. $\bullet$, $n_{II\infty}$ values obtained from the relationship $g_{K2\infty} - E$ varying as $(\bar{g}_{K2\infty}/\bar{g}_{K1})^{1/4}$. The relationship $g_{K2\infty} - E$ was constructed from amplitudes of instantaneous I_K associated with repolarising E steps from various values of E_1 (given by abscissa) to the same value of E_2 , –100 mV (details are given in refs 15, 16). The $n_{II\infty} - E$ curve was drawn by eye and its ordinates were fed into the computer in 5-mV steps along the abscissa. b, Function $\tau_{nII}(E)$ for the slow K channel used for computation of sensory nerve firing behaviour in Fig. 2. τ_{nII} values were calculated from experimental time constants τ_{K2} determining the decline of g_{K2} tails following repolarisation from constant value of E_1 , 67 mV, to various values of E_2 (given by abscissa) by the following equation:

$$\bar{g}_{K2} \cdot \left[(n_{II\infty}(E_1) - n_{II\infty}(E_2)) \exp\left(-\frac{t}{\tau_{nII}}\right) + n_{II\infty}(E_2) \right]^4$$

$$= (g_{K20} - g_{K2\infty}) \exp\left(-\frac{t}{\tau_{K2}}\right) + g_{K2\infty}$$

where g_{K20} is the g_{K2} value at the moment just after a repolarising step, and $g_{K2\infty}$ is its steady-state value at E_2 . The solution was obtained for $t = \tau_{K2}$ assuming $n_{II\infty}(67 \text{ mV}) = 1$ (see a), $g_{K20} = \bar{g}_{K2} \cdot n_{II\infty}^4(67 \text{ mV}) = \bar{g}_{K2}$, $g_{K2\infty} = \bar{g}_{K2} \cdot n_{II\infty}^4(E_2)$. For $n_{II\infty}$ of ~0.3 (that is, for $E_2 \geq -110$ mV), $\tau_{nII} \approx \tau_{K2}/n_{II\infty}(E_2)$. τ_{nII} were scaled to 22°C (as in Hille's equations for τ_n in *R. pipiens*¹⁷) with a Q_{10} of 3.0. $\circ$, τ_{nII} measured, as described, with E_1 40 mV; $\bullet$, the same, with E_1 500 mV; $\bullet$, τ_{nII} obtained from depolarising E steps as described in a. The smooth curve was drawn by eye and its ordinates were fed into the computer in 5-mV steps along the abscissa.

Fig. 2. Effect of the slow K current $I_{K_{II}}$ on firing behaviour of amphibian sensory nerve associated with a constant current step of 0.9 nA. Increase in $I_{K_{II}}$ is due to increase in $\bar{g}_{K_{II}}$ (0, 10, 20, 30 and 40%, respectively, in a, b, c, d and e of $\bar{g}_{K_{II}}$ (maximum K conductance through the fast K channels)). As $I_{K_{II}}$ in *R. ridibunda* is an additional process to the *R. pipiens* sensory nerve¹⁶, all the basic data necessary for this computation were those tabulated for *R. pipiens* by Hille¹⁷, except for h_0 which was chosen to be 0.9286 to induce the repetitive activity as in a. Abscissa: time (ms), ordinate: membrane potential (mV).

sensory nerves capable of SFA, the slow K channels are likely to be generally similar to those in *R. ridibunda*¹³, so that the physiological basis for SFA must be common to different amphibians.

Slow K channels might also provide a mechanism additional to or underlying that described¹⁸ for sensory compared with motor fibres. Sensory fibres respond to a constant current step by producing a train with increasing interspike intervals, whereas motor fibres respond by producing one or very few spikes³. Thus, motor fibres can be considered quickly adapting. The $n_{\infty}-E$ curve for motor fibres was found to be displaced from that for sensory fibres in a hyperpolarising direction¹⁸, which damps repetitiveness (our unpublished calculations). However, this displacement and consequently the mechanism for sensory compared with motor fibres may be the result of greater $\bar{g}_{K_{II}}$ in motor than sensory fibres, for $\bar{g}_{K_{II}}$ is activated by more negative ranges of membrane potential than is $\bar{g}_{K_I}$ (refs 15, 16). Thus, in Fig. 1 the 0.5 n_{∞} value is at $E = -92$ mV whereas the 0.5 n_{∞} value for *R. ridibunda* usually lies between -50 and -60 mV¹⁶, as 0.5 n_{∞} for *R. pipiens*^{1,17}. Then the shift of the curve of $n_{\infty}-E$ for overall $\bar{g}_K$ (as measured before¹⁸) will increase with $\bar{g}_{K_{II}}$, that is, with the density of the slow K channels. It is tempting to suggest that neurones in the ventral roots synthesise more slow K channels than neurones in the dorsal roots.

The sensory nerves of *R. pipiens* usually seem to have only fast K channels. This follows from I_K measurements, indicating that they obey¹ the Cole-Moore translation principle²⁰, and from noise measurements suggesting a two-state open-closed transition for the K channels involved²¹. Both tests would fail if I_K in this node were due to more than one population of K channels (it was the analysis of I_K currents associated with the Cole-Moore translation test that led to the discovery of the slow K channels in *R. ridibunda*^{15,16}). However, as SFA also occurs (rarely) in *R.*

*pipiens*¹, our hypothesis suggests that a slow K channel must occur, if rarely, in this specimen as well, but that the yield of the gene product for the slow K channel is lower here than in other species.

The only other example for which SFA has been explained in terms of the HH theory concerns neurones from the mollusc *Archidoris*²². The SFA phenomenology here differs considerably from that in amphibian nerves, especially in that spike trains here are finite²². However, this is the picture that results from computation of the firing behaviour when the current through the slow K channel involved (which considerably differs from that in the node) is taken into account. Thus, in two markedly different cases of SFA (in the node and the neurone), the current through the corresponding slow K channel is sufficient to describe basic characteristic features of SFA. There are many different types of slow K channels in biological membranes (reviewed in ref. 23) and, except for (or together with) the cases where an electrogenic pump is involved²⁴, the diversity in SFA phenomenology in nerve cells of different types is probably mainly due to diversity of slow K channels. The mechanism discussed here might also apply to adaptational behaviour of sustained and transient receptors responding to a stationary component of generator potential, as shown in Fig. 2b, c and d, e, respectively.

We thank Professor O. B. Ilyinsky for encouragement and discussion and Dr E. N. Timin for help with the computer program and advice.

Labelling of benzodiazepine receptors *in vivo*

THE presence of benzodiazepine receptors has been demonstrated using isolated membrane preparations from the mammalian central nervous system¹⁻³. Specific binding of ³H-diazepam to synaptosomal membranes is maximal at temperatures of 0-4 °C, but reduced by more than 95% at physiological temperatures⁴. Although the inhibition of ³H-diazepam binding by other benzodiazepines *in vitro* closely parallels their pharmacological potencies *in vivo*, failure to demonstrate specific binding in physiological conditions raises questions as to whether receptor binding occurs *in vivo*. We report here that benzodiazepine receptors can be demonstrated in the intact

animal following intravenous administration of ³H-diazepam. The labelling of benzodiazepine receptors *in vivo* permits studies of receptor occupancy in various pharmacological and physiological conditions as well as autoradiographic localisation of the receptor *in situ*.

Adult male Sprague-Dawley rats (125–175 g) were used in all studies. ³H-Diazepam (39.08 Ci mmol⁻¹, NEN) was diluted with 50% ethanol to a final volume of 300 μl and administered through the lateral tail vein. Studies in this (unpublished) and other laboratories⁵ have demonstrated that the maximum brain concentration of diazepam occurs within 1–2 min of intravenous administration. At this time 95% of the radioactivity in brain is authentic diazepam, as demonstrated by thin layer chromatography⁵. Animals were decapitated 1 min after injection and the tissues to be assayed were immediately dissected, weighed and frozen on dry ice (–70 °C). Studies designed to test the effects of freezing on the amount of specifically bound ³H-diazepam revealed no differences between fresh and frozen samples. Therefore, subsequent studies were carried out using frozen specimens, giving greater efficiency and control over assay and homogenisation time.

For assay of membrane-bound ³H-diazepam, tissues were homogenised in 25 volumes of ice-cold 50 mM Tris-HCl buffer (pH 7.4) using a Brinkmann polytron (20 s, full speed). Aliquots of the homogenate were sampled for total and membrane-bound ³H-diazepam. The latter was determined by filtering the homogenate (0.1–1.0 ml) through Whatman glass fibre filters (GF/B) followed by two rinses of ice-cold Tris-HCl buffer (5 ml each). The filters were then placed in scintillation vials containing 10 ml of Aquasol (NEN), shaken thoroughly and counted with a Beckman LS-250 liquid scintillation counter.

Membrane-bound radioactivity was linear with tissue concentration in homogenates containing up to 20 mg of brain tissue (wet weight). Preliminary studies were carried out to determine whether the specific membrane-bound radioactivity was a result of *in vitro* binding that might have occurred artefactually following homogenisation. In an experiment comparing the amount of specifically bound ³H-diazepam with post-homogenisation incubation time, both specific and nonspecific binding were maximal at the earliest time tested (30 s post-homogenisation) and did not change over a 60-min period. As saturation of benzodiazepine receptors *in vitro* occurs approximately 10 min after incubation^{4,6}, these data support the assumption that the binding observed following intravenous administration had occurred *in vivo*. The results also demonstrate the stability of the drug-receptor complex when the preparation is kept at 0–4 °C.

Fig. 1 Stereospecific inhibition of ³H-diazepam binding *in vivo*. Rats were injected with 50 μCi ³H-diazepam in combination with the enantiomers of B9 or B10 (700 μg kg⁻¹). Values represent $\bar{X} \pm \text{s.e.m.}$ in brain ($n = 8$), liver ($n = 6$) and other tissues ($n = 2$). Per cent of ³H-diazepam bound is the amount of ³H-diazepam in the homogenate retained by the 6F/B filter divided by the amount of ³H-diazepam in an equal volume of homogenate $\times 100$. ■, Active isomers (B9(+), B10(+)); □, inactive isomers (B9(–), B10(–)).

Co-injection of the ³H-diazepam with unlabelled clonazepam (250 μg kg⁻¹) or the pharmacologically active benzodiazepine enantiomers B9(+) and B10(+) (700 μg kg⁻¹) dramatically reduced membrane-bound ³H-diazepam (40.7 ± 2.1% ($n = 5$) compared with 7.72 ± 1.54% ($n = 5$) bound) whereas the total concentration of ³H-diazepam in brain was unaffected. Substitution of the pharmacologically inactive enantiomers B9(–) or B10(–) did not produce any significant decrease of membrane-bound ³H-diazepam (39.8 ± 1.2% bound). Homogenisation of the tissue in buffer (50 mM Tris-HCl, pH 7.4) containing 3 μM unlabelled diazepam resulted in a rapid displacement of more than 90% of membrane-bound radioactivity. The latter experiment agrees well with observations *in vitro* indicating that more than 90% of the ³H-diazepam bound to crude synaptosomal fractions of brain is displaced by this concentration of diazepam^{1,3}.

Table 1 Regional distribution of benzodiazepine receptors *in vivo*

Region	Specific ³ H-diazepam binding (pmol per g tissue)	Nonspecific binding (% of total binding)
Cortex	12 ± 2.0	12
Hypothalamus	8.7 ± 0.7	19
Midbrain	7.6 ± 0.7	20
Striatum	6.8 ± 1.7	32
Septal region	6.2 ± 0.2	17
Cerebellum	6.2 ± 0.7	50
Pons medulla	5.5 ± 0.6	20

Rats were injected intravenously with 50 μCi ³H-diazepam. The various brain regions were hemisected, one half of each region being homogenised in 50 mM Tris buffer (pH 7.4) with or without 3 μM diazepam, and assayed in triplicate within 15 min of homogenisation. Specific binding is defined as the amount of ³H-diazepam bound after homogenisation in Tris buffer minus the amount bound after homogenisation with 3 μM diazepam. Values represent the mean ± s.e.m. of brain regions from three rats.

As *in vitro* studies have shown that benzodiazepine receptors are highly localised to brain^{1,4}, it was of interest to study the tissue distribution of ³H-diazepam binding *in vivo*. Figure 1 shows the binding of ³H-diazepam in brain and peripheral tissues with and without co-injection of a pharmacologically active benzodiazepine. Although ³H-diazepam binds to membranes of all the peripheral tissues studied, only the binding in brain is displaced in a stereospecific fashion. Similar results have been reported *in vitro*⁴. Finally, we investigated the regional distribution of benzodiazepine receptors in brain (Table 1). The rank order concentration of benzodiazepine receptors in various cortical and subcortical areas is identical to that observed in the *in vitro* assay⁴.

Our results demonstrate the feasibility of labelling benzodiazepine receptors *in vivo* in physiological conditions. These receptors are highly localised to the CNS, and to cortical areas in particular. Displacement of specific binding occurs only with pharmacologically active benzodiazepines, thus supporting a role for these sites as pharmacological receptors mediating the action(s) of these drugs within the CNS.

In addition to establishing specific binding of ³H-diazepam to benzodiazepine receptors in physiological conditions, *in vivo* labelling of benzodiazepine receptors may also permit further studies on receptor changes during various pharmacological and/or physiological states, as well as autoradiographic visualisation of the receptor. Similar *in vivo* studies using ³H-flunitrazepam have also been carried out (R. Chang and S. Snyder, personal communication).

We thank Hoffmann-LaRoche for diazepam, clonazepam, B9(+) (Ro 11-3129), B9(–) (Ro 11-3625), B10(+) (Ro 11-

6896) and B10(-) (Ro 11-6893). S.M.P. and M.J.W. thank Dr J. Axelrod for providing laboratory facilities. P.S. thanks Dr. J. Daly and the NIAMDD for providing facilities.

An endogenous protein modulates the affinity of GABA and benzodiazepine receptors in rat brain

BIOCHEMICAL^{1,2} and neurophysiological³⁻⁵ evidence has suggested that benzodiazepines may relieve anxiety facilitating the synaptic action of γ -aminobutyric acid (GABA), an important neurotransmitter in the brain of mammals, including man. As benzodiazepines fail to increase the turnover of GABA stored presynaptically as would be expected if they were to act as indirect GABA agonists, and since it has been difficult to demonstrate a direct agonistic action of the benzodiazepines on GABA postsynaptic receptors²⁻⁷ *in vitro*, the molecular mechanism whereby benzodiazepines facilitate GABAergic transmission is still unknown. Independent investigators⁸⁻¹⁰ have recently reported the presence of a high affinity, saturable, stereospecific binding site for benzodiazepines in synaptic membrane preparations obtained from brain of different animal species, including man. This high affinity binding is now used to determine the therapeutic potency and to study the mode of action of benzodiazepines in anxiety.

Any known transmitter, including GABA, fails to compete with the benzodiazepines for their specific brain receptors; however, the brain distribution pattern of these benzodiazepine receptors is similar to that of the Na^+ -independent high affinity binding sites for GABA (8,9). This and analogies in the pharmacological profile of GABA-mimetics and benzodiazepines^{2,11} has suggested to us that studies of the mechanism whereby benzodiazepine receptors interact with the Na^+ -independent GABA receptor sites may help to understand the mode of action of these antianxiety drugs.

The discovery that benzodiazepine receptors are present in the central nervous system has also led to the proposal¹² that: "by analogy with the discovery of opiate receptor, the benzodiazepine receptor assay may even offer a simple means for the discovery of a naturally occurring ligand for such receptor: the brain's own antianxiety substance".

Recently, we reported that a small thermostable protein ('endogenous inhibitor') which noncompetitively reduces the affinity of GABA for its Na^+ -independent recognition site, could be extracted from brain preparations enriched with synaptic membranes¹³. This endogenous inhibitor is thermostable (at 95°C for 10 min), has acidic characteristics, and when

purified 1,500-fold by gel filtration, ion-exchange chromatography, and preparative polyacrylamide gel electrophoresis, gives on 10, 15 and 20% SDS polyacrylamide gel only one major protein band equivalent to a molecular weight of ~15,000. The present report shows that pharmacologically-active benzodiazepines modulate the affinity of GABA for its recognition

Fig. 1 Scatchard analysis of interaction between diazepam and 'endogenous inhibitor' of Na^+ -independent ^3H -GABA binding. Crude synaptic membranes from rat cerebral cortex¹⁵ were frozen at -20°C for 24 h and treated for 30 min at 37°C with 0.01% Triton X-100. After centrifugation at 40,000g for 10 min the pellet was dispersed with a polytron in 50 volumes of 50 mM Tris-citrate (pH 7.1) without Triton X-100. This operation was performed twice. Specific GABA binding was calculated by subtracting from the binding which occurred by incubating the membranes at 4°C for 5 min with ^3H -GABA, the binding that occurred by incubating with ^3H -GABA plus 10^{-3}M unlabelled GABA. Only ^3H -GABA (40 Ci mmol $^{-1}$) was used when the lowest concentrations of ligand (1-30 nM) were tested, and a constant amount of ^3H -GABA (30 nM) plus various concentrations (30-120 nM) of nonradioactive GABA when the highest concentrations of the ligand were tested. The ligand tested was contained in 100 μl which was incubated with a standard aliquot (200 μg protein) of membranes dispersed in 900 μl of 50 mM Tris-citrate (pH 7.1). After incubation the reaction was terminated by centrifuging at 48,000g for 10 min. The supernatant was discarded and the pellet rapidly rinsed with cold H_2O and suspended in NCS (Amersham-Searle solubiliser) before counting. To study the action of the endogenous inhibitor, membranes were incubated at 0°C for 15 min, with 7.5 μg of 500-fold purified endogenous inhibitor before the addition of ^3H -GABA. When the effect of diazepam was studied membranes were preincubated at 0°C for 15 min with $8 \times 10^{-7}\text{M}$ diazepam before addition of inhibitor. Membranes incubated at 0°C without the inhibitor or diazepam served as controls. Scatchard analysis revealed two affinity components for GABA binding. The apparent K_D for the low affinity component was: 111; 240 and 286 nM for control, diazepam + endogenous inhibitor and endogenous inhibitor, respectively. The apparent K_D for the high affinity component was: 28 and 33 nM for control and diazepam + endogenous inhibitor, respectively. A high affinity component for ^3H -GABA binding was not measurable in membranes preincubated with the endogenous inhibitor alone. In the insert the values of the specifically bound (SB) ^3H -GABA are plotted against the concentrations of ^3H -GABA in the incubation mixture. Proteins were determined with the method of Lowry¹⁸. ●, Control; △, diazepam + inhibitor; ○, inhibitor only.

site by competing with the endogenous inhibitor. In addition, this endogenous protein reduces the apparent affinity of diazepam for its recognition site. To study whether diazepam could change the activity of the endogenous inhibitor, the inhibitor was purified 500-fold using a previously described procedure¹³. In brief, the entire rat brain was homogenised in 5 mM Tris-citrate buffer (pH 7.1). After centrifugation, the supernatant was incubated at 95°C for 10 min and successively dialysed filtered on CF 50A Amicon membrane and chromatographed on Sephadex G-100 column. It was then purified further with Dowex 50X8 ion-exchange chromatography where it behaved as an acidic protein.

As shown in Fig. 1a, the addition of this purified inhibitor to a crude preparation of synaptic membranes free of endogenous inhibitor (the inhibitor was removed by freezing and thawing and by treatment with Triton X-100, for details see Fig. 1 legend), resulted in a substantial change of the kinetic characteristics of Na⁺-independent ³H-GABA binding. Scatchard plot analysis of these data indicates that the addition of purified endogenous inhibitor to crude synaptic membrane preparations concealed the Na⁺-independent high affinity recognition sites for GABA and also changed the kinetic characteristics of the low affinity GABA binding sites (see Fig. 1). If the membranes were preincubated with diazepam, the action on the endogenous inhibitor on both high and low affinity components of GABA binding was reduced (Fig. 1). The data of Fig. 1 indicate that the action of the endogenous inhibitor on GABA binding is apparently noncompetitive, and suggest a negative cooperative interaction between the inhibitor and the GABA recognition sites. Diazepam added in concentrations up to 10⁻⁵ M failed to change the binding of ³H-GABA to an inhibitor-free crude synaptic membrane preparation, but increased the affinity binding of ³H-GABA to a fresh crude synaptic membrane preparation (see also ref. 14). Freshly prepared membranes revealed Na⁺-independent binding for ³H-GABA with an apparent K_D of ~200 nM (low affinity component)¹⁵. As we have previously reported¹³, the appearance of a high affinity component for ³H-GABA binding in the fresh membrane preparation is prevented by the presence of the endogenous inhibitor. When fresh membranes were preincubated with diazepam (5 × 10⁻⁷ M) there was a change in the kinetic characteristics of the ³H-GABA binding due to the appearance of a high affinity site with an apparent K_D of 36 nM in addition to the low affinity binding component (K_D = 200 nM). Hence, the addition of diazepam to a fresh membrane preparation changes the kinetics of GABA binding in a way similar to that elicited by the removal of the endogenous inhibitor by freezing, thawing washing with Tris buffer and treatment with Triton X-100 as described previously¹³.

The nature of the interaction between the various benzodiazepines and the endogenous inhibitor was then studied by challenging different amounts of the endogenous inhibitor with a constant concentration of benzodiazepines. Figure 2a and b show the effects of 10⁻⁶, 10⁻⁷ and 10⁻⁸ M diazepam and of 10⁻⁷ M Ro-11(+) (a pharmacologically active benzodiazepine, see Fig. 2 legend) and Ro-11(-) (the inactive isomer) on the inhibition of the high affinity ³H-GABA binding induced by the addition of increasing amounts of the endogenous inhibitor to the inhibitor-free membranes. In the presence of benzodiazepines, the amount of inhibitor required to produce an inhibition of the high affinity GABA binding was increased. The difference was particularly significant when small doses of the inhibitor were used. For example, 2.5 µg of the endogenous inhibitor produced ~50% inhibition of the GABA binding in controls or in Ro-11(-)-treated membranes. The same amount of the endogenous inhibitor produced 10, 18 and 32% inhibition in the presence of 10⁻⁶, 10⁻⁷, 10⁻⁸ of diazepam, respectively and 12.5% in the presence of 10⁻⁷ M Ro-11(+). The double reciprocal plot of the data indicates an apparent competitive interaction between the purified endogenous inhibitor and diazepam or Ro-11(+) (see inserts of Fig. 2a and b). The Hill plot analysis of the data gives a Hill coefficient for diazepam- and

Ro-11(+)-treated membranes higher than the Hill coefficient for membranes treated with solvent or Ro-11(-). This confirms that the negative cooperative action of the endogenous inhibitor on ³H-GABA binding is reverted by pretreating the membranes with pharmacologically active benzodiazepines.

We have also tested the potency of a few benzodiazepines to compete with the endogenous inhibitor of GABA binding. Flunitrazepam and clonazepam were four to five times more potent than diazepam but diazepam was at least 10 times more potent than chlordiazepoxide and medazepam. These results suggest that the potency of different benzodiazepines in preventing the inhibition of the high affinity Na⁺-independent GABA binding by the endogenous inhibitor correlates with their binding affinity to saturable sites in rat brain membrane preparations^{8,9} and with the known pharmacological *in vivo* potency as antianxiety agents¹⁶.

The interaction between benzodiazepines and the endogenous inhibitor of Na⁺-independent GABA binding raises the question of whether the endogenous inhibitor interacts with benzodiazepines because it functions as a soluble benzo-

Fig. 2 Interaction of diazepam (a) or Ro-11 (b) with various amounts of endogenous inhibitor of Na⁺-independent ³H-GABA binding. Crude synaptic membranes from rat cerebral cortex were prepared by successive freezing, thawing and washing with Tris buffer plus treatment with Triton X-100 as for Fig. 1. Membranes were preincubated at 0°C for 15 min with diazepam (a) or Ro-11(+) or Ro-11(-) (b) before addition of inhibitor. In the insert double reciprocal plot of the data is shown, revealing an apparent competitive interaction between diazepam, Ro-11(+) and the endogenous inhibitor (I). This gives K values of 0.91 µg of inhibitor for controls, 3.3, 5.2 and 10.2 µg for 10⁻⁸ M, 10⁻⁷ M and 10⁻⁶ M diazepam, respectively, and 9.2 µg of inhibitor protein for 10⁻⁷ M Ro-11(+). Ro-11(+) = Ro-113128; [(+)-5-(*O*-chlorophenyl)-1,3-dihydro-3-methyl-7-nitro-2 H -1,4-benzodiazepine-2-one] is pharmacologically active and Ro-11(-) = Ro-113624 is inactive. Results similar to those reported here were obtained in five experiments with diazepam and in five with Ro-11. The average dose of the inhibitor which produced a 25% inhibition of the GABA binding is 0.5 ± 0.018 µg in 10 preparations of the control membranes, 25% inhibition was achieved with $1.5 \mu\text{g} (\pm 0.082)$, $2.5 \mu\text{g} (\pm 0.10)$ and $4 \mu\text{g} (\pm 0.28)$ of endogenous inhibitor in the presence of 10⁻⁸, 10⁻⁷ and 10⁻⁶ M of diazepam, respectively. A 25% inhibition was achieved with $0.45 \mu\text{g} (\pm 0.020)$ of endogenous inhibitor in the presence of Ro-11(-) and with $3.8 \mu\text{g} (\pm 0.30)$ in the presence of Ro-11(+). The difference between the controls and the Ro-11(-) is not significant. The difference between the controls and different diazepam doses among the different benzodiazepines doses and between Ro-11(-) and Ro-11(+) is statistically significant ($P < 0.05$).

Fig. 3 Scatchard plot of the ^3H -diazepam binding to control or endogenous inhibitor-treated crude synaptic membranes. Frozen, thawed and Triton X-100 treated crude synaptic membranes were prepared as described in Fig. 1. Specific ^3H -diazepam binding was calculated by subtracting the binding which occurred by incubating the membranes at 4°C for 15 min with ^3H -diazepam ($0.75\text{--}24\text{ nM}$; 40 Ci mmol^{-1}), the binding that occurred by incubating with ^3H -diazepam and 10^{-6} M unlabelled diazepam⁹. Concentrations ($0.75\text{--}24\text{ nM}$) of ^3H -diazepam ($100\text{ }\mu\text{l}$) were incubated with a standard aliquot ($200\text{ }\mu\text{g}$ protein) of membranes dispersed in $900\text{ }\mu\text{l}$ of 50 mM Tris-citrate ($\text{pH } 7.1$). The equilibrium binding was terminated by filtration under vacuum through Whatman CF/B glass-fibre filters which were washed twice with 5 ml ice-cold Tris-citrate buffer $\text{pH } 7.1$. When the action of the endogenous inhibitor was studied, the membranes were incubated at 0°C for 60 min in presence of $30\text{ }\mu\text{g}$ of 500-fold purified endogenous inhibitor before addition of ^3H -diazepam. Membranes incubated at 0°C for 60 min without diazepam served as controls. Scatchard analysis gave a K_D of $\sim 6\text{ nM}$ for controls and 24 nM for inhibitor-treated membranes. In the insert, the values of specifically bound (SB) ^3H -diazepam are plotted against the concentrations of ^3H -diazepam in the incubation medium. ○, Controls; ●, inhibitor present

diazepine binding site or as an endogenous modulator of the benzodiazepines for their recognition site in crude synaptic membranes. In fresh membranes (rich in endogenous inhibitor), the extent of diazepam binding is less than in frozen and Triton X-100 treated membranes (free of endogenous inhibitor). Thus, these results exclude the possibility that the endogenous inhibitor acts as a soluble benzodiazepine recognition site.

The data reported in Fig. 3 indicate that the endogenous inhibitor has some of the characteristics expected of a molecule that modulates the affinity of benzodiazepine receptors for this drug. The affinity of ^3H -diazepam for frozen Triton X-100-treated membrane preparations preincubated at 0°C for 60 min with the endogenous inhibitor was reduced when compared to that of similar membranes preincubated without endogenous inhibitor (Fig. 3). The action of the endogenous inhibitor on ^3H -diazepam binding (see Fig. 3) at 0°C was evident only when the endogenous inhibitor was preincubated with the membranes for 15 min or more. Preincubation of crude synaptic membranes with the endogenous inhibitor failed to change the kinetic profile of the recognition site of muscarinic receptors as studied by QNB binding¹⁷.

In summary, the present experiments (compare Figs 1 and 3) indicate that an endogenous inhibitor protein isolated and purified from fresh membrane preparations acts noncompetitively with GABA for its Na^+ -independent recognition site and interacts with diazepam binding. The function of diazepam binding is expressed as a modulation of the affinity of GABA recognition sites. Although binding of diazepam or of endogenous inhibitor modifies GABA binding, they do not exert this effect by binding to GABA binding sites. This regulatory site may be linked to the high affinity site for benzodiazepine binding for which this endogenous inhibitor may act as a modulator or a natural agonist.

This inference agrees with the lack of competition between GABA and ^3H -diazepam for specific binding to brain membranes: moreover, it is in keeping with the relationship between the brain location of ^3H -diazepam and ^3H -GABA binding sites⁹ and is supported by the pharmacological interactions between diazepam and GABA receptor blockers^{1,3}. The apparent decrease in the affinity for ^3H -diazepam binding in brain synaptic membranes pretreated with the endogenous inhibitor could suggest that the endogenous inhibitor is functioning as a natural ligand for the benzodiazepine receptors. However, interpretation of these data requires caution because the time constants of our measures are not sufficiently short. In fact, we are dealing with a very complex system in which the theoretical assumption of a rapid reversible equilibrium implied by any inference derived from the Scatchard analysis may not be satisfied. Although our data clearly indicate that the 'endogenous inhibitor' may act as an 'endogenous modulator' of the benzodiazepine binding, it is at present impossible to establish whether this occurs as a result of a direct action at the high affinity receptor sites for the benzodiazepines or indirectly through an allosteric effect which involves the GABA/benzodiazepine/ Cl^- ionophore supramolecular complex. Studies are now in progress to elucidate this problem. These studies may also help to clarify the supramolecular nature of the postsynaptic GABA receptors and the role of the endogenous inhibitor protein in the regulation of the affinity of ^3H -GABA for the Na^+ -independent GABA recognition site. Preliminary work in our laboratory indicates that diazepam displaces the endogenous protein inhibitor from its physiological binding sites also *in vivo*. Whether a change in the amount of this endogenous inhibitor bound to synaptic membranes plays a part in determining the level of anxiety is not yet known but this can now be investigated.

Is there a correction mechanism in the 5S multigene system?

RIBOSOMAL GENES are present in many copies per cell in all living species. They are the classic example of the tandemly repeated multigene system, and have been studied in a wide variety of organisms, including man^{1,2}, *Drosophila*^{3,4}, *Xenopus*^{5,6} and *Escherichia coli*⁷. Reiteration of these genes is presumably necessary to ensure the production of the large amounts of ribosomal and 5S RNA required for use in the ribosomes. However, the possession of multiple copies of a gene poses a special problem for evolution. If a lethal or deleterious mutation occurred in one gene of, for example, the 24,000 present for the 5S DNA in *Xenopus*⁵, this would have no selective disadvantage for the organism. What then prevents the accumulation of lethal mutations in such a system? Presumably if the number of effective genes were reduced significantly natural selection would operate. But it has been suggested that a 'correction mechanism'⁸ exists to maintain the homogeneity of the multigene system without a requirement for natural selection. We show here that two cloned repeats of *Xenopus* oocyte 5S DNA are very similar but not identical in sequence. The similarity strongly suggests that a correction mechanism is operating, but it is not so precise as to cause the different repeats to be identical. A small but distinct degree of heterogeneity is tolerated.

Two main kinds of correction mechanism have been proposed—'sudden' and 'gradual'. The master-slave hypothesis⁹ (a sudden mechanism) envisages the matching of a number of 'slave' sequences to a single 'master' once per life cycle. Thus neighbouring repeats or slaves should be identical. In the oocyte 5S DNA of *Xenopus laevis* adjacent repeating units are clearly heterogeneous in length¹⁰, ruling out this mechanism. A gradual mechanism called 'crossover fixation' has been proposed by Smith¹¹ and envisages a high rate of unequal crossing over, causing the fixation of multiple copies of a single ancestral repeat. This seems a more plausible theory, but the extent to which it operates is uncertain because the real extent of correction or homogeneity between the members of a multigene system has never been absolutely clear.

We have examined the extent of correction in detail for the oocyte 5S DNA gene system in *Xenopus laevis*. This DNA consists of a high A+T rich spacer made up of many short subrepeats followed by a G+C rich region which is a duplication of 174 nucleotides, containing the 5S gene and also a 'pseudogene' structure. The overall organisation of a repeat unit is shown in Fig. 1. Previous work on the oocyte 5S RNA¹²⁻¹⁴ has shown that it is a mixture of molecules, but the real extent of heterogeneity could not be assessed accurately¹³. Recently the entire sequence of total frog 5S DNA was determined^{15,16} but, again, microheterogeneity remained undetected, because a mixture of sequences was studied. We have compared the entire sequence of two cloned repeat units of oocyte 5S DNA, Xlo 5

and Xlo 31. These are by definition unique species, so that the sequences obtained must actually exist and are not averaged¹⁷.

The sequence of these repeat units was determined by the Maxam and Gilbert technique¹⁸. Typical sequencing gels are shown in Fig. 2. The complete sequence of clone Xlo 5 is shown in Fig. 3 with the differences present in clone Xlo 31 indicated. Two types of microheterogeneity were found. The first involved the addition or deletion of oligonucleotide blocks in the A+T rich spacer region. This phenomenon has been previously noted

Fig. 2 Two thin gels¹⁹ showing different parts of the sequence of the 193-long *Hae*III fragment of Xlo 5. Missing residues denoted by X are methylated Cs situated in *Eco* RII restriction methylation sites¹⁶.

Fig. 1 Location of gene and pseudogene and the *Hae*III and *Hind*III sites in the 5S DNA monomer.

The concept of unequal crossing over is compatible with the observed sequence microheterogeneity. As noted previously¹⁵ the presence of the 15-long oligonucleotide within a larger repeat structure correlates well with the prediction of the development of short and long range periodicities within the A+T spacer region¹¹. We must now assume that natural

selection will eliminate mutations in the promoter regions, whereas a level of heterogeneity in the spacer and gene regions can be tolerated. The extent to which the correction mechanism works on the gene sequences need only be enough to keep the heterogeneity of the 5S RNA in ribosomes within a limit which the animal can tolerate. As the precise function of 5S RNA is unknown, this limit is unclear, but is perhaps not more than a few mutations per the 'averaged' 5S RNA sequence'.

We thank D. D. Brown for providing the two 5S DNA plasmids studied.

Splicing of SV40 late mRNA is a post-transcriptional process

THE synthesis and metabolism of SV40 mRNA is being used as a model system to study RNA transcription and processing in animal cells. We and others have recently reported the finding of a novel mechanism of viral RNA maturation in SV40-infected cells¹⁻⁷ in which the leader sequences (those found at the 5' ends of the main bodies of SV40 late mRNAs) and the adjacent coding sequences are transcribed from non-contiguous segments of the viral DNA. Similar observations have been reported for adenovirus mRNAs^{8,9}. This process is known as splicing and may proceed by several possible routes. These include: intermolecular ligation of RNA; deletion in the DNA template of the intervening sequences; looping out of intervening DNA sequences so that the RNA polymerase could skip over short distances; and deletion of the appropriate intervening RNA sequences at the post-transcriptional level. We present here an analysis of R-loop structures¹⁰ formed between nuclear and cytoplasmic poly(A)⁺ RNAs and linear SV40 DNA, which provides support for the last of these possibilities⁴⁰. A similar analysis has been carried out for β -globin mRNA¹⁷.

It has been shown that nuclear poly(A)⁺ viral RNA accumulates in the nucleus of the infected cell (refs 9, 10 and Y.A., M.H., O.L. and Y. Reuveni, submitted for publication). Figure 1 shows that the majority of the poly(A)⁺ viral RNAs present in the nuclei of infected cells sediment in sucrose gradient as 19S components: only a minor fraction sediments faster than 19S and no 16S poly(A)⁺ viral RNA is observed.

R-loops were obtained by annealing nuclear or cytoplasmic 19S poly(A)⁺ RNA with double-stranded linear SV40 DNA obtained by cleavage of form I DNA with *Bgl*I or *Taq*I restriction endonucleases. *Bgl*I and *Taq*I cleave form I DNA at 0.67 and 0.58 map units respectively¹. Figures 2 and 3 show the appearance of representative R-loop structures with their schematic tracings. There are two striking differences in the appearance of the R-loops: (1) the 5' ends of the R-loops pertaining to the nuclear RNAs are closer to the restriction

Fig. 1 Sedimentation analysis of nuclear poly(A)⁺ viral RNA. Forty-eight hours after infection of BSC-1 cells with plaque-purified SV40 stock (strain 777), cells were labelled with ³H-uridine for 5 h and labelled nuclear RNA extracted¹³. The ³H-RNA was dissolved in 1 ml of 0.5 M NaCl, 0.01 M Tris-HCl pH 7.4 and fractionated on an oligo-dT-cellulose column (0.5 × 3 cm) as described before¹⁴. Poly(A)⁺ RNA was eluted from the column with 0.01 M Tris-HCl pH 7.4 and collected by ethanol precipitation and centrifugation. Sedimentation analysis of the labelled RNA was performed in 15-30% (w/w) sucrose gradient in SDS buffer¹⁵, centrifuged for 16 h at 25,000 r.p.m. at 20°C in a Spinco SW27 rotor. At the end of the run, fractions were collected and the radioactivity counted in Triton-based scintillation fluid. Twenty-five-microlitre aliquots from each fraction were hybridised to SV40 DNA immobilised on nitrocellulose filters in 4 × SSC at 68°C for 20 h, as previously described¹⁰. Fractions 10-20 were collected and used for the R-loop analysis.

Fig. 2 Electron micrographs and their tracings of R-loops composed of linear SV40 DNA (form I cleaved at position 0.67 map units with *Bgl*I restriction endonuclease)¹ and cytoplasmic 19S poly(A)⁺ RNA in *a* or nuclear poly(A)⁺ RNA in *b*. Preparation of the R-loops for electron microscopy was as detailed in ref. 3. In the tracing the letters represent: *a*, double-stranded DNA; *b*, free tail of poly(A); *c*, a heteroduplex DNA-RNA which includes the body of the RNAs; *d*, displaced single-stranded DNA; *e*, free tail of a 'leader'³; *a'*, double-stranded DNA. See text for differences between R-loops pertaining to nuclear and cytoplasmic 19S poly(A)⁺ RNAs. Scale bars = 0.5 μ m.

enzyme cleavage sites than are the 5' ends of those pertaining to the cytoplasmic RNAs; (2) free leaders are often seen at the 5' ends of the R-loops pertaining to the cytoplasmic 19S RNA (in about 70% of the molecules), whereas they are observed much less frequently in the R-loops pertaining to the nuclear 19S viral RNA (in about 10% of the molecules).

Figure 4 is a histogram summarising the map positions of the 5' ends of nuclear and cytoplasmic 19S poly(A)⁺ RNAs. The position of the 5' termini of the cytoplasmic RNA species (dark histogram) is represented by a reasonably sharp histogram with a mean at coordinate 0.77 ± 0.01 . The histogram for the location of the 5' termini of the nuclear viral RNAs (striped histogram) is skewed towards an upstream position and is more heterogeneous. The apparent sharpness of the histogram in nuclear RNA/SV40 DNA (*Bgl*I) (Fig. 4a) results presumably from the fact that the 5' ends of the R-loops are close to the *Bgl*I cleavage site and are therefore less stable. Indeed, 'opened' forked R-loops were observed in this preparation. The small peak at coordinate 0.95 represents a minor contamination with cytoplasmic 16S RNA which is the predominant viral RNA accumulating in the infected cells. The heterogeneity of the location of the 5' ends of nuclear viral RNAs is consistent with a model previously suggested for transcription of prokaryotic DNA¹⁶. Accordingly, several RNA polymerases bind to a short stretch of DNA from which they are released in succession to begin transcription.

The ability of the precursor nuclear poly(A)⁺ viral RNA to anneal to the entire length of the late portion of SV40 DNA (~0.67–0.17 map units) including the corresponding interruptions between the leaders and the bodies of the cytoplasmic mRNAs indicates that splicing is a post-transcriptional process. Splicing of the precursor poly(A)⁺ viral RNA may occur in the nucleus before the RNA molecule is transported to the cytoplasm. It is possible, however, that splicing occurs during the transport from the nucleus to the cytoplasm or immediately after the molecule has reached the cytoplasm. The excision–ligation

Fig. 3 Electron micrographs and their tracings of R-loops composed of linear SV40 DNA (form I cleaved at position 0.58 map units with *Taq*I restriction endonuclease)¹ and cytoplasmic 19S poly(A)⁺ RNA in *a* or nuclear poly(A)⁺ RNA in *b*. See Fig. 2 for explanations.

Fig. 4 Histogram of the locations, on the physical map of SV40, of the 5' ends of the bodies of the 19S poly(A)⁺ nuclear and cytoplasmic viral RNAs. The locations of the 5' ends of the bodies of the viral RNAs were determined from measurements of molecules as in Figs 2 and 3. The distances between the 5' end of the R-loop and the restriction enzyme cleavage site (*a*' in the tracing) were measured and expressed for each molecule as the fractional length of the viral DNA. The locations on the physical map of SV40 DNA were determined by adding the value obtained to 0.67 in *a* and to 0.58 in *b*. The dark histogram is cytoplasmic RNA and the striped histogram is nuclear RNA.

reaction in the precursor RNA molecule is carried out, presumably, by an enzyme(s) which recognises short base-paired sequences in the precursor RNA molecule. This reaction would represent a novel mechanism in the regulation of gene expression in animal cells.

3'-Terminal labelling of RNA with T4 RNA ligase

T4 RNA LIGASE catalyses the formation of an internucleotide phosphodiester bond between an oligonucleotide donor molecule with a 5'-terminal phosphate and an oligonucleotide acceptor molecule with a 3'-terminal hydroxyl¹⁻³. Although the minimal acceptor must be a trinucleoside diphosphate, dinucleoside pyrophosphates and mononucleoside 3',5'-bisphosphates (pNps) are effective donors in the intermolecular reaction⁴⁻⁶. We demonstrate here that various high molecular weight RNA molecules are acceptors in the RNA ligase reaction even when present in very low concentrations in the reaction mixture. One immediate consequence of this observation is that a convenient method for labelling the 3' end of RNA molecules *in vitro* becomes available. By using a [5'-³²P]pNp as a donor and RNA as an acceptor, the product of the reaction is an RNA molecule one nucleotide longer, with a 3'-terminal phosphate and a ³²P-phosphate in the last internucleotide linkage. This reaction is therefore analogous to the *in vitro* labelling of the 5' termini of RNA chains with polynucleotide kinase and [γ -³²P]ATP and can be used in situations where 5' labelling is not possible. In addition, the ability to add various donors to an RNA molecule should allow the function of the 3' terminus of the molecule to be investigated.

Twelve different purified preparations of one or more RNA species were tested for their ability to act as acceptors in the RNA ligase reaction (Table 1). These RNAs varied in chain length from ~870 nucleotides (smallest of the 10 segments of the reovirus genome⁷) to ~15,000 nucleotides (Sendai virus RNA⁸). [5'-³²P]pAp or pCp, the donors in these reactions, were prepared from [γ -³²P]ATP and the corresponding 3' monophosphate using T4 polynucleotide kinase. In extensive studies with oligomers⁵ and tRNA⁹, pCp is found to be the more reactive donor and is, therefore, preferable for 3'-end labelling.

Table 1 3' End labelling of RNA

RNA (source)	Concentration of acceptor in reaction (nM)	Yield (%)
<i>E. coli</i> 16S rRNA (C. Cantor)	120	42
<i>E. coli</i> 23S rRNA (D. Shapiro)	40	18
<i>E. coli</i> 23S + 16S rRNA (S. Rose)	200	44

Reactions were carried out in a total volume of 30 μ l in the following conditions: 1 μ g RNA (12–220 nM), [5'-³²P]pAp (1 μ M, 850–1,520 Ci mmol⁻¹), ATP (5 μ M), HEPES (50 mM, pH 8.3), MgCl₂ (10 mM), dithiothreitol (3.3 mM), dimethyl sulphoxide (10%, v/v), glycerol (15%, v/v) and RNA ligase (400 units ml⁻¹, 200 μ g ml⁻¹), and incubated at 4 °C for 24 h. (The RNAs were provided by those named in parentheses.) Yields were determined from the amount of radioactivity precipitable on a nitrocellulose filter in 5% trichloroacetic acid (TCA), 100% reaction equalling the number of mols of RNA added. However, as several samples were contaminated with smaller RNAs their values generally represent an overestimate of the yield. For example, high levels of incorporation were not expected for STNV RNA, as about 50% of the 3' ends are blocked with a phosphate¹⁸. Analysis on a 20% acrylamide gel indicated that the majority of TCA-precipitable label was incorporated into oligomers less than 80 nucleotides in length.

Fig. 1 Analysis of RNA ligase reactions by vertical, denaturing polyacrylamide gel electrophoresis. Aliquots from reactions in 9 M urea-glycerol (1:1, v:v) were loaded on to acrylamide slab gels (19:1, acrylamide:bisacrylamide; 3 mm $\times$ 22 cm) containing 7 M urea, 90 mM Tris-borate (pH 8.3) and 10 mM EDTA¹⁹ and electrophoresed at 250 V at 25 °C with the borate-EDTA as running buffer. In adjacent wells, 1–3 μ g of the unreacted RNAs were run. Radioactive bands were visualised by autoradiography. The lines indicate the position of the unreacted RNAs visualised with 'Stains-All'. a, BMV₍₁₋₄₎, BMV₄, reovirus and STNV were electrophoresed for 16 h on a 4% acrylamide gel. b, 16S rRNA, 23S plus 16S RNA, 18S rRNA, 28S rRNA, Q β and Sendai were electrophoresed for 20 h on a 2.5% acrylamide gel.

Each reaction contained 1 μ g of RNA, a substantial excess of donor and ATP, and a high concentration of RNA ligase (5 μ M). A low temperature (4 °C) and long incubation time (> 16 h) were chosen to minimise the rapid loss of RNA ligase activity which occurs at higher temperatures^{5,10}. Finally, we have found that the extent of reaction is increased two- to threefold⁵ by including 10% dimethyl sulphoxide in the reaction mixture.

Analysis of the yields by acid precipitation of the RNA and Millipore filtration indicated that although all 12 RNA preparations were acceptors, the efficiency of the reaction varied considerably. Differences in the concentration of 3' termini cannot be the only cause for this, as no correlation between yield and concentration was observed. The sequence and the secondary structure at the 3' end of the RNA are also thought to affect the reaction yield. Comparison of oligonucleotide acceptors indicates that the composition of the terminal three nucleotides has a strong influence on yield⁵. The known specificity of RNA ligase for single-stranded RNA¹¹ can account for the low yield encountered for the 'blunt', double-stranded end of reovirus RNA and suggests that a 3'-terminal secondary structure could explain the comparatively low yields with other RNAs.

In Fig. 1, the products of the reactions in Table 1 are analysed by acrylamide gel electrophoresis in 7 M urea, where the secondary structure of RNA is minimised. Autoradiography of the gels reveals that the major ³²P-labelled RNA bands migrate closely with the major staining bands. This observation supports the conclusion that the [5'-³²P]-labelled nucleotide bisphosphate has been added on to the 3' end of the RNA. When a mixture of RNA molecules was used in a reaction (*Escherichia coli* rRNA, brome mosaic virus (BMV) and reovirus) all species were labelled to a similar extent. In addition, contaminating RNAs present in the reaction mixture are also labelled. In several of these cases, the smaller contaminants have run off the end of the gel and can only be detected with higher percentage

gels. However, we can exclude fragmentation of the product during the ligation reaction, as smaller RNAs are not observed in all cases.

In several of the reactions in Table 1, the ^{32}P -labelled RNA products have been purified from the unreacted bisphosphate and any low molecular weight impurities by Sephadex G-100 column chromatography. Complete digestion of these RNAs with a mixture of ribonucleases A, T_1 and T_2 and analysis of the products by high-voltage paper electrophoresis give a single ^{32}P -labelled nucleoside monophosphate corresponding to the known 3'-terminal nucleotide of the RNA molecule (Fig. 2). In the case of double-stranded reovirus RNA, analysis of a T_1 digest of the labelled RNA indicates that the 3' ends of both the plus and the minus strands were being labelled to a similar extent (A. Shatkin, personal communication). Finally, it is important to note that no reaction occurs at the 3' hydroxyl of m⁷G of the 'cap' structures on reovirus RNA, BMV RNA or ovalbumin mRNA. It is unlikely that cap structures will be substrates for RNA ligase, as a trinucleoside diphosphate is required as a minimal acceptor^{2,5} and isolated Ado5'ppp5'Guo was found to be inactive as a donor⁴.

The use of T4 RNA ligase to label the 3' end of RNA *in vitro* offers several advantages over other methods of *in vitro* labelling of RNA. First, the 3' ends of RNA molecules are usually free 3' hydroxyl groups and therefore can be used directly as acceptors for RNA ligase. In contrast, labelling the 5' ends of RNA with T4 polynucleotide kinase is often complicated by the presence of one or more 5'-terminal phosphates or the 'cap' structure, which must be removed before the labelling reaction can be carried out. Second, as endonucleolytic breakdown products of RNAs will often have a 3'-terminal phosphate and a 5'-terminal hydroxyl, they will be labelled by polynucleotide kinase but not by RNA ligase. Thus, RNA ligase reactions will have fewer radiolabelled contaminants. Third, in contrast to other *in vitro* procedures that are limited to a single isotope^{12,13}, nucleoside 3',5'-bisphosphates may be prepared as 5'- ^{32}P or with ^3H or ^{14}C in the nucleoside. (^{125}I)5-iodocytidine 3',5'-bisphosphate is also a donor in the RNA ligase reaction⁹. Finally, as preparations of RNA ligase can be made free of nucleases and the reaction conditions are extremely mild, the labelled RNA can be recovered intact in high yields.

Fig. 2 Nearest-neighbour analysis of 3'-end labelled RNA. The RNAs from ligation reactions were purified by gel filtration on Sephadex G-100, ethanol-precipitated and degraded completely with a mixture of RNases A, T_1 and T_2 according to Barrel²⁰. The 3' mononucleotides were resolved by paper electrophoresis on Whatman no. 1 in 0.025 M Na citrate, pH 4.0, at 4,500 V for 2 h (ref. 21). The sequences of the 3' termini of 18S rRNA, Q β , BMV₄, Sendai and reovirus have been reported elsewhere (refs 22, 23, 17, 24, 25, respectively).

RNA with a radiolabel at the 3' end may be used to determine the sequence of nucleotides near the label by one of several recently developed methods¹⁴⁻¹⁶. For example, 15 nucleotides of the 3'-terminal sequence of BMV-4 RNA were confirmed¹⁷ with material prepared in this work by using the two-dimensional 'wandering-spot' sequencing procedure (R. Dasgupta and P. Kaesberg, personal communication). Thus, 3'-terminal labelling with RNA ligase complements 5'-terminal labelling with polynucleotide kinase, and the two methods may be used to study the sequence at both ends of a molecule and, if the molecule is short enough, confirm the results of the other method.

We thank our colleagues (listed in Table 1) for RNA samples, Dr L. Beres and NEN for samples of (5'- ^{32}P)pNp's, and V. Cameron for technical assistance. This work was supported by NIH grant GM 19059.

Cloning of replication origins from the *E. coli* K12 chromosome

MINIPLASMIDS, containing only an origin of replication and plasmid-coded functions necessary for plasmid replication and maintenance have been isolated from larger plasmids¹. The technique used was to cleave the parent plasmid with the restriction endonuclease *EcoRI* and reanneal and ligate the fragments so generated in the presence of another *EcoRI*-generated fragment of DNA coding for a β -lactamase. This second fragment was not capable of self-replication but hybrids between it and a plasmid fragment which was able to replicate could be detected because calls of *Escherichia coli* transformed with such hybrids would be resistant to ampicillin. We have used the same technique to isolate minichromosomes from the total chromosomal DNA of *E. coli* K12 and have found that two different chromosomal *EcoRI* fragments can function as autonomously replicating plasmids. One type of plasmid is indistinguishable from that isolated independently by Yasuda and Hirota² and contains the origin of replication normally active in chromosome replication termed *oriC* (refs 3-6). The other type, which we call *oriJ* plasmids to distinguish them from

oriC plasmids, are described below. Both types can be isolated from a single strain of *E. coli* and they contain chromosomal DNA which is not homologous in DNA-DNA hybridisation studies. Consequently we conclude that the *E. coli* K12 chromosome contains at least two segments of DNA capable of self-replication.

The fragment of DNA coding for β -lactamase (the Ap fragment) used in our study was obtained from an amplifiable ColE1-Ap plasmid (pLG1) which was constructed by *in vivo* ligation of the Ap fragment (4.5 megadaltons) of the plasmid pSC122 (ref. 1) with ColE1 DNA which had been cleaved at its single *EcoRI* site. ColE1-Ap amplified by incubation of its host in chloramphenicol⁷ was purified⁸ and cleaved with *EcoRI* and the Ap fragment separated in an equilibrium density gradient of CsCl, making use of a density difference between it ($\rho = 1.693$) and the linear form of ColE1 ($\rho = 1.710$) (ref. 7).

In one experiment, an Ap fragment preparation (1 μ g) was annealed and ligated⁹ with an *EcoRI* digest of *E. coli* K12 DNA (3 μ g) isolated from strain C600 (ref. 10) by Marmur's method¹¹. After dialysis, the ligation mixture was used to transform¹³ the F⁻ *recA* strain AB2463 (ref. 12), and ampicillin resistant transformants were selected on appropriately supplemented M9 synthetic medium¹⁴ containing ampicillin (40 μ g ml⁻¹). Before plating the transformed cells were incubated in LB broth¹⁵ for 90 min at 37 °C to permit expression of the β -lactamase gene. Of 1,600 ampicillin-resistant colonies which emerged, 1,000 were tested and 5 found to be sensitive to colicin E1. Three of these gave ampicillin-sensitive segregants, and were found to contain plasmid DNA when total lysates¹⁶ were analysed in CsCl-ethidium bromide equilibrium density

gradients¹⁷. DNA isolated from C600, AB2463, and a pooled extract from 10 ampicillin-sensitive segregants of one ampicillin resistant clone, contained no detectable plasmid DNA.

Each of the three plasmids from the ampicillin-resistant, colicin-sensitive clones gave two *EcoRI* cleavage fragments, one of 4.5 megadaltons corresponding to the Ap fragment and another of 8.3 megadaltons. They seemed to be identical on the basis of subsequent analysis with *HindIII*. One of them, called *oriJ*-Ap (pLG2), was subjected to further analysis. Interestingly, none of these first three plasmids had an *EcoRI* fragment of 5.9 megadaltons as reported for the *oriC* plasmids. The 8.3 megadaltons fragment is not a derivative of ColE1 (4.2 megadaltons), the only other replicon known to be involved in our protocol, and is not derived from contaminating DNA. Both alternatives were ruled out by DNA-DNA hybridisation using a modification¹⁸ of Southern's¹⁹ method. *OriJ*-Ap DNA was labelled to high specific activity with ³²P by nick-translation¹⁸. This DNA was then used as a probe to test for hybridisation against *EcoRI*-digested ColE1 DNA, Ap DNA, *EcoRI*-digested *oriJ*-Ap DNA, an *EcoRI* digest of *E. coli* DNA from strain C600 and an *EcoRI*-digest of bacteriophage λ C1857 DNA. No hybridisation occurred between ColE1 and *oriJ*-Ap (Fig. 1a, b) indicating that they contain no extensive sequence homology and thus that the latter is not derived from the former. As a control it can be seen that both *EcoRI* fragments of *oriJ*-Ap (Fig. 1e, f) and the Ap fragment (Fig. 1c, d) hybridised with *oriJ*-Ap DNA. Figure 1g, h shows that *E. coli* DNA contains an *EcoRI* fragment 8.3 megadaltons in size which hybridises with *oriJ*-Ap. On the other hand (data not shown) the Ap fragment itself shows no hybridisation with *E. coli* DNA, hence the hybridisation seen in Fig. 1h must be between *E. coli* DNA and the 8.3 megadalton fragment of *oriJ*.

The two *EcoRI* fragments of bacteriophage λ C1857 DNA which contain the cohesive ends²⁰ gave a faint reaction with the *oriJ*-Ap probe but no hybridisation was detected with the 4.7-megadalton fragment which contains the origin of phage replication²⁰ (Fig. 1, track j). Note that in Fig. 1 the exposure time for track j was 8 times longer than for other tracks. The significance of the faint reaction is not clear but the absence of homology with the 4.7-megadalton fragment suggests that *oriJ* is not derived from λ DNA which might be present in the C600 chromosome.

A further study of the structure of *oriJ*-Ap was made by a combination of restriction analysis with *EcoRI* and *HindIII* enzymes and hybridisation with a ³²P-labelled Ap DNA probe. The results obtained are shown in Fig. 2 and confirm that the 4.5-megadalton *EcoRI* fragment of *oriJ*-Ap is the Ap fragment used in the cloning experiment, and are consistent only with the restriction map shown in Fig. 2B or with one in which the order of the 2.4- and 1.4-megadalton segments is reversed. Restriction analysis with *Bam*HI enzyme (data not shown) confirm the order given in Fig. 2B.

To compare the restriction map of *oriJ* with that of the homologous 8.3-megadalton fragment of C600 chromosomal DNA, ³²P-labelled *oriJ*-Ap was hybridised against C600 DNA digested with *EcoRI*, *HindIII* or both endonucleases (Fig. 2C). An analysis of the molecular weights of the major hybridisation bands shows that the 8.3-megadalton fragment present in the C600 chromosome generates a family of *HindIII* fragments indistinguishable from the fragments generated by the 8.3-megadalton component of *oriJ*-Ap. Thus it seems that a single segment of chromosomal DNA has been incorporated into *oriJ*-Ap probably without major structural rearrangements. The data in Fig. 2C also provide information about the location of the two *HindIII* cleavage sites adjacent to the 8.3-megadalton segment and these are indicated in Fig. 2D.

It is conceivable that different K12 strains have different restriction target maps in the neighbourhood of the chromosome origin and that *oriJ* and *oriC* both contain the same origin of replication. Strain KL228 (ref. 21) is an Hfr from which F-prime derivatives have been isolated that carry a 5.9-megadalton *EcoRI* fragment inside a restriction map which is

Fig. 1 Homology studies with *oriJ*-Ap DNA. *OriJ*-Ap (0.5 μ g) was labelled with ³²P (1–5 $\times 10^6$ cpm μ g⁻¹) by nick-translation¹⁸. This probe was hybridised^{18,19} to DNA (0.1–0.15 μ g) that had been previously digested to completion with *EcoRI*, fractionated by electrophoresis (90 min at 150 V) in 0.8% agarose containing Tris-borate-EDTA buffer²⁹, denatured in the gel by treatment with alkali and finally blotted onto nitrocellulose filters. Hybridisation was carried out in 3 $\times$ SSC at 65 °C for 2 d. The filters were given a post-hybridisation wash in 3 $\times$ SSC followed by 0.1 $\times$ SSC at 65 °C. Hybridisation bands were detected by autoradiography using a Kodak X-Omat film that was exposed to the filters at –80 °C for 18 h (tracks b, d, f, h) or 6 d (track j). The ethidium-bromide pattern (left) and the corresponding DNA material that hybridises with the probe (right) are shown in pairs: tracks (a) and (b) ColE1 DNA $\times$ *EcoRI*, (c) and (d) Ap fragment, (e) and (f) *oriJ*-Ap $\times$ *EcoRI* (control), (g) and (h) C600 DNA $\times$ *EcoRI* and (i) and (j) λ C1857 DNA $\times$ *EcoRI*. (Molecular weights of λ fragments: 13.7, 4.7, 3.7, 3.5, 3.0 and 2.0 megadaltons respectively; 3.7 and 3.5 megadalton fragments are not resolved in the gel).

indistinguishable from that of the 5.9-megadalton fragment of *oriC* (ref. 4). When *oriJ*-Ap was used as a probe to test for hybridisation with an *EcoRI* digest of DNA from KL228, no hybridisation was found in the 5.9-megadalton region (Fig. 2C, track d). On the contrary, the hybridisation pattern against the *EcoRI* digest and a *HindIII* digest (Fig. 2A, d and e) of this DNA indicates that it contains the *oriJ* segment. Thus KL228 probably contains both the *oriC* and *oriJ* segments.

If the two plasmids are derived from distinct regions of the K12 chromosome then both should be recoverable in a single DNA preparation. The fact that none of the three ampicillin resistant clones isolated by us contained *oriC* plasmids whereas all three such clones isolated in a similar way by Yasuda and Hirota did so, suggested that the choice of recipient strain might

Fig. 2 Physical analysis of *oriJ*-Ap and of the homologous *E. coli* K12 chromosomal region. **A**, Combined restriction and hybridisation analysis of *oriJ*-Ap. *oriJ*-Ap (0.3 μ g) was digested with *EcoRI*, *HindIII* or both enzymes, and the products fractionated by electrophoresis in agarose gel and hybridised with Ap DNA (0.5 μ g) labelled with ^{32} P as indicated in Fig. 1. The Ap fragment (0.1 μ g) was also included in the gel as a control for subsequent hybridisation with this probe. The ethidium bromide pattern (left) and the corresponding DNA material that hybridises with the probe (right) are shown in pairs. Tracks (a) and (b), Ap fragment (control); (c) and (d), *oriJ*-Ap $\times$ *EcoRI*; (e) and (f), *oriJ*-Ap $\times$ *HindIII*; (g) and (h), *oriJ*-Ap $\times$ *EcoRI* $\times$ *HindIII*. Molecular weights of the fragments are given in megadaltons and were calculated using λ cf857 DNA $\times$ *EcoRI* fragments as standard. **B**, Physical map of the *oriJ*-Ap plasmid based on data in (A). Broad curve, Ap fragment; thin curve, chromosomal material; arrows, *HindIII* restriction target. The two *EcoRI* targets are at the two junctions of the Ap fragment and the chromosomal DNA. **C**, Hybridisation analysis of *E. coli* DNA with *oriJ*-Ap. *oriJ*-Ap (0.5 μ g) was used as a ^{32} P-labelled probe to test for hybridisation with DNA from *E. coli* strains C600 and KL228 which had been digested with *EcoRI* and/or *HindIII* enzymes. All operations were basically as described in Fig. 1 except that the electrophoresis was run for 12 h at 20 V. Tracks (a), (b) and (c) show respectively hybridisation found against C600 DNA digested with *EcoRI*, *HindIII*, and both enzymes. Tracks (d) and (e) show hybridisation found in KL228 treated with *EcoRI* and *HindIII* respectively. Molecular weights of the hybridisation bands are given in megadaltons and were calculated as before. **D**, Two alternative *HindIII* maps (a and b) of the homologous region to *oriJ* in the *E. coli* chromosome based on data in (C) assuming that the orders of the fragments in the chromosome and the *oriJ* probe are identical (thick line).

be important. In particular it seemed possible that the use of an Hfr strain as recipient might favour the isolation of *oriC* plasmids because in such strains the predicted interference of such a plasmid with chromosome replication as a consequence of control of copy number²² might be alleviated because chromosome replication could be driven by the integrated F factor^{23,24}. We also noticed that on rich medium there was selection against colonies containing the *oriJ*-Ap plasmid. We therefore prepared a new ligation mixture of *EcoRI* digested C600 DNA (1.5 μ g) and Ap DNA (1.5 μ g), transformed the Hfr LC248 (ref. 2) with it and selected ampicillin-resistant colonies on LB medium containing 20 μ g ml⁻¹ ampicillin as indicated by Yasuda and Hirota². Five colicin E1 sensitive clones which segregated ampicillin sensitive cells were found among 300 ampicillin resistant colonies. Plasmid DNA (pLG6) isolated from one of these colonies chosen at random was analysed in the manner described for *oriJ*-Ap. It was found to be indistinguishable from *oriC* on the basis of its distribution of *HindIII* and *EcoRI* sites and homologous DNA fragments of similar size were found in C600 DNA. In addition, the sizes of the fragments which hybridise with *oriC* are those predicted if the *HindIII* sites adjacent to the 5.9-megadalton *oriC* fragment are at the locations found by Marsh and Worcel³. Thus we conclude that pLG6 is probably identical to *oriC*. This conclusion is confirmed by the data shown in Fig. 3 which also demonstrate that *oriC* and *oriJ* do not cross-hybridise with each other. In this experiment, DNA from the bacteriophage λ asn 132 (ref. 25), a hybrid λ which contains a segment of chromosomal DNA including an origin of replication within a 5.9-megadalton *EcoRI* fragment^{25,26}, was cleaved with *EcoRI* and the *EcoRI* fragments tested for homology with pLG6 by hybridisation. An *EcoRI* digest of *oriJ*-Ap was included in the same experiment. It can be seen that pLG6 hybridises with the 5.9-megadalton fragment of λ asn 132 (Fig. 3a, b), thus confirming that pLG6 is homologous with the *oriC* region as defined by others^{2,3,25,26}. In addition, there is no hybridisation between pLG6 DNA and the 8.3-megadalton fragment of *oriJ* indicating that the two origin plasmids share no significant homology (Fig. 3c, d).

Fig. 3 Hybridisation analysis of λ asn 132 and *oriJ*-Ap with *oriC*-Ap. *oriC*-Ap was labelled with ^{32} P and used as a probe to test for hybridisation with λ asn 132 DNA (0.3 μ g) digested with *EcoRI* and *oriJ*-Ap DNA (0.2 μ g) digested with *EcoRI*, basically as described in Fig. 1. λ asn 132 was isolated from strain CM848 (*E. coli* K12 F⁺, *thi. asn* (λ asn 132, λ cf857 S7): source K. von Meyenburg) using published methods³⁰. Tracks (b) to (d) show, in pairs, the ethidium bromide pattern (left) and the corresponding hybridisation picture (right): (a) and (b) λ asn 132 DNA $\times$ *EcoRI* (c) and (d) *oriJ*-Ap $\times$ *EcoRI*. The hybridisation pattern found in the *oriC* region was obtained after 3 h exposure of the autoradiograph and the one found in the Ap region after 60 h exposure. Molecular weights of the λ asn 132 *EcoRI* fragments (megadaltons): 8.2, 6.0, 4.7, 3.7 (3.5), 2.5, 2.0, 1.2.

In relation to the location and functions of the segment of chromosomal DNA which gives rise to *oriJ* plasmids, it is pertinent to note that several authors^{27,28} have postulated the existence of a cryptic prophage integrated in the *sbcA-rac* region of the *E. coli* chromosome and that interestingly the strain that we used as a host for *oriJ*-Ap lacks this prophage. It is noteworthy to mention in this respect that we found a drastic reduction in the transformation frequency with *oriJ*-Ap in some other strains of *E. coli* K12. A full structural analysis of the *sbcA-rac* region in C600 and AB2463 strains and a study of the replication of *oriJ*-Ap in these hosts is in progress.

It is not yet clear to what extent the efficiency of isolation of *oriC* plasmids is influenced by the use of an Hfr recipient as opposed to an F⁻. We have observed that the Hfr recipient LC248 and the F⁻ recipient AB2463 are transformed with similar efficiency by *oriC*-Ap with selection on either M9 or LB media but that the *oriC* plasmid caused a much more severe inhibition of growth of the F⁻ strain than of the Hfr particularly on M9 medium. The basis of these differences in growth rate are being analysed in more detail and in particular the hypothesis that chromosome replication is driven by the inserted F plasmid in Hfr *oriC* strains is being tested directly.

We thank S. Falkow, J. Collins, K. von Meyenburg, B. Wilkins, M. Chandler and R. Rowbury for strains; K. von Meyenburg for data before publication; A. Stereochemistry of phosphoryl group transfer using a chiral [¹⁶O, ¹⁷O, ¹⁸O] stereochemical course of alkaline phosphatase

THE recent synthesis and stereochemical analysis of a phosphate monoester chiral at phosphorus by virtue only of the three stable isotopes of oxygen^{1,2} opens the way to the determination of the stereochemical course of both chemical and enzymatic reactions that involve the transfer of a phosphoryl group. We report here the first determination of the stereochemical consequence at phosphorus of an intermolecular phosphoryl transfer reaction. In studying the reaction catalysed by alkaline phosphatase we had two aims: first, to discover the stereochemical course of this well-studied transfer, and second to devise a general method by which the configuration of any chiral phosphate monoester can be determined.

The alkaline phosphatase from *Escherichia coli* is a nonspecific phosphate monoesterase³, and there is good evidence that the readily-formed phosphoryl enzyme is a reaction intermediate in the mechanistic pathway normally followed by this enzyme³. As with many other enzymes that catalyse hydrolytic reactions, alkaline phosphatase readily catalyses the transfer of phosphoryl groups to acceptors other than water, such as alcohols⁴. As our method for determining the absolute configuration of a chiral [¹⁶O, ¹⁷O, ¹⁸O]phosphoryl group requires its attachment to one enantiomer of propane-1,2-diol, this compound was used as the acceptor in the present experiments.

Phenyl[(*R*)-¹⁶O, ¹⁷O, ¹⁸O]phosphate was prepared as the crystalline dicyclohexylammonium salt by the method outlined in Fig. 1, which closely parallels that used earlier to prepare [1(*R*)-¹⁶O, ¹⁷O, ¹⁸O]phospho-(*S*)-propane-1,2-diol¹. The disodium salt of chiral phenyl phosphate (270 mg) was dissolved in water (4.0 ml) containing KHCO₃ (1.2 mmol), K₂CO₃ (1.2 mmol), Zn(OAc)₂ (30 nmol), and Mg(OAc)₂ (3 μmol). (*S*)-Propane-1,2-diol (4.0 ml) was added, and the reaction initiated with alkaline phosphatase (10 units *E. coli* enzyme, Sigma). When 49% of the phenyl phosphate had been solvolysed, the reaction was stopped by the addition of Dowex 50 (H⁺ form). The mixture of 1- and 2-phosphopropane-1,2-diols was isolated by ion-exchange chromatography on DEAE-cellulose and on Dowex 1 in 30% yield (based on the phenyl phosphate consumed). This material comprised the 1- and 2-isomers in 9:1 ratio, from which the 1-isomer of phosphopropane-1,2-diol was obtained (containing <3% of the 2-isomer) by crystallisation of the dicyclohexylammonium salt from acetone-water at -20 °C. The isotopic composition of the peripheral phosphate oxygens was: ¹⁶O, 43.7%; ¹⁷O, 15.3%; and ¹⁸O, 41%. These percentages were identical (to within 1%) with the isotope ratios for the peripheral oxygens of the phenyl phosphate starting material.

The absolute configuration of the product 1- [¹⁶O, ¹⁷O, ¹⁸O]phosphopropane-1,2-diol was then determined by the sequence described earlier¹ (this involves ring closure, methylation of an exocyclic oxygen, separation of the resulting diastereoisomeric triesters, methanolytic ring opening, and linked-scan metastable ion mass spectrometry). The configuration at phosphorus in the product was found to be *R* (92% ± 6%), showing that the phosphoryl group has been transferred with overall retention of configuration at phosphorus.

Of all enzymes that involve the transfer of a phosphoryl group (including phosphatases, phosphokinases and phosphomutases), the alkaline phosphatase from *E. coli* is one of the most thoroughly investigated. The evidence that the isolable phosphoryl enzyme is indeed an intermediate on the normal reaction pathway is good³, and the process is evidently of the 'double-displacement' class⁵. It is therefore gratifying to find

Fig. 1 Synthesis of phenyl[(R)- ^{16}O , ^{17}O , ^{18}O]phosphate and enzyme-catalysed transfer of the chiral phosphoryl group to (S)-propane-1,2-diol.

that the stereochemical consequence of this reaction is indeed retention. While we cannot yet define the stereochemical course of each of the two single displacement steps (the formation of the phosphoryl-enzyme and its collapse), the probability that the phosphorylation is effectively (even if not precisely) the microscopic reverse of the dephosphorylation, makes overall retention the anticipated result. Further, this work in principle allows the absolute configuration of any chiral [^{16}O , ^{17}O , ^{18}O]phosphate monoester to be determined, facilitating the definition of the stereochemical course of phosphoryl transfer reactions that are mechanistically ambiguous.

Nanosecond transient Raman spectra of photolysed carboxyhaemoglobin

CONFORMATIONAL CHANGES accompanying the photolysis of carboxyhaemoglobin (CO-Hb) have been the subject of much recent study. It is known from time resolved absorption studies that the process is not simple, comprising various steps on time scales ranging from picoseconds to milliseconds¹⁻⁶. Removal of the CO molecule is complete within picoseconds⁵, but the existence of an unknown transient with a 100 ns lifetime has been demonstrated¹. No conclusion has been possible as to the time required for the reorganisation of the porphyrin core. In principle, resonance Raman scattering offers a more detailed source of conformational information. From steady state Raman spectra, the normal modes have been identified^{7,8}. A clear empirical correlation has been found⁹ between the position of the resonantly enhanced anomalously polarised line in the region 1,550-1,590 cm^{-1} , and the porphyrin core size. Here we report the first nanosecond time-resolved spectra of CO-Hb. From our results it is clear that the main reorganisation of the porphyrin core occurs within 5 ns of photolysis.

Human haemoglobin was prepared according to the standard methods. It was reduced with sodium dithionite and then isolated in 0.01 M phosphate buffer (pH 7) by Sephadex chromatography. This stock solution was stored as CO-Hb under an oxygen-free atmosphere. The samples of CO-Hb diluted from this stock solution were sealed under ~1 atm CO. Solutions of deoxy-Hb were sealed under an N_2 atmosphere after the samples had been rendered free of both O_2 and CO in photolytic conditions. The concentration of the samples, measured using optical absorption in the region 5,300-5,700 Å, was typically 0.1-0.3 mM haem.

The spectra were recorded on an optical multichannel analyser of our own design, which has been previously described¹⁰. The time resolution of this apparatus has been increased by more than four orders of magnitude by the use of the pulsed Nd:YAG laser described below. A spectral region up to 200 cm^{-1} wide may be observed, thereby eliminating problems associated with shot-to-shot variation of laser power when pulsed lasers are used. When required, it is possible to gate the input slit using a Kerr cell with a switching time of 3 ns. The time resolution is then improved to ~5 ns. In the spectra reported here, the input slit was set at 250 μm , corresponding to a spectral resolution (FWHM) of 6 cm^{-1} . In all cases the spectrometer was calibrated as to absolute position by measurements on the 1,588 cm^{-1} line of benzene to eliminate backlash effects in the gratings.

Two excitation sources were used. The pulsed spectra were excited by a Nd:YAG laser, frequency-doubled to provide nominal 20 mJ pulses of 5,320 Å radiation with a duration of 10 ns, and a pulse repetition rate of 10 ps^{-1} . In order to obtain cw spectra in similar resonance conditions, a Kr⁺ laser was used, operating at 5,308 Å, at a power of 10-20 mW. The cw beam was sharply focused (~100 μm), while, to avoid damage to the sample container, it was necessary to defocus the YAG pulse to provide a beam diameter of ~750 μm . The resulting peak intensity of 400 MW cm^{-2} is below threshold for any stimulated processes in this system. Both sets of spectra were taken in a rotating sample cell cooled externally by flowing cold nitrogen gas. For the pulsed spectra, these conditions yield a lifetime for the CO-Hb in the laser beam of about 0.3 ns, while for the continuous wave spectra it is estimated to be about 1 ms. Since the latter time is much longer than the time for the rotating cell to turn through the sample volume (~150 μs), the cw spectra represent largely unphotolysed material. In the pulsed case, on the other hand, the first 5% of the pulse was sufficient to photolyse the entire sample. Hence the pulsed spectra represent

mainly photolysed material within 10 ns after photolysis. Since the rotation time of the cell (100 ms) was much larger than the 10 ms recombination time at 1 atmosphere of CO, each pulse was presented with essentially a fresh sample for study. Each spectrum reported here represents the accumulation of 1,600 or more laser pulses.

The essential results are demonstrated by the spectra shown in Fig. 1. The cw spectrum (Fig. 1a) shows the strong anomalously polarised 1,585 cm^{-1} peak characteristic of low spin haem¹¹. The pulsed spectra of CO-Hb (Fig. 1b) obtained with the entire 10 ns pulse, exhibit the disappearance of this line, and the appearance of another strong feature in the region 1,545–1,555 cm^{-1} . This feature seems to consist of two unresolved lines, similar to the spectrum of deoxy-Hb taken in the same conditions. Spectra on a sample of oxy-Hb showed little evidence of photolysis, as expected. The anomalously depolarised component of the doublet (B) is displayed more accurately by subtraction of the weighted polarised spectrum (VV) from the depolarised (VH), using the fact that the depolarisation ratio for the lower member of the doublet is 0.75, by symmetry. Typical results are shown in Fig. 1c. The observed peak positions are tabulated in Table 1. The line B has been found to be correlated

Table 1 Observed line positions (cm^{-1})

Sample	A (dp)	B (ap)	C (dp)
CO-Hb (cw)		1,585 $\pm$ 2	1,634 $\pm$ 2
CO-Hb (pulsed)	1,544 $\pm$ 1	1,554 $\pm$ 1	1,601 $\pm$ 1
Deoxy-Hb (pulsed)	1,547 $\pm$ 1	1,556 $\pm$ 1	1,606.5 $\pm$ 1
Oxy-Hb (pulsed)		1,587 $\pm$ 3	1,640 $\pm$ 3

with porphyrato core size. Hence, the spectra shown demonstrate that the major change in core size occurs in less than 10 ns after photolysis. By the use of the Kerr cell it was possible to observe separately the scattering from the first and second

halves of the 10 ns laser pulse. These spectra, although noisier than those shown in Fig. 1, were essentially the same, clearly showing that the main change in the porphyrato core size occurs within 5 ns of photolysis. Hence, this reorganisation is completed well before the 100 ns lifetime of the transient observed in ref. 1.

The better quality of the spectra obtained with the full 10 ns pulse, shown in Fig. 1, allows the further conclusion that definite (small) shifts of all three lines are observed between the pulsed spectra of CO-Hb and deoxy-Hb. In the case of CO-Hb, the process is initiated with the haem in the *R* configuration, while the deoxy-Hb it is in *T*. The *R*–*T* transition occurs on a much longer time scale¹. Hence, the small differences observed may be associated with the changes in haem geometry during the *R*–*T* transition. However, we should note the possible existence of a long-lived electronically excited state⁶ in either case (or both) which might itself cause perturbations of the Raman frequencies. Further, the correlation observed between core size and Raman frequency⁹ shows a scatter of 4–5 cm^{-1} . Therefore, the shifts we observe, although apparently indicative of a change of 0.02 Å in the core size, may instead be the result of the protein reorganisation. Therefore, we cannot state conclusively on the basis of our spectra that a change in haem geometry is associated with the *R*–*T* transition.

As has been noted by others¹², the observation that the core size changes after photolysis does not necessarily imply a movement of the Fe ion out of the plane. Possible distortions of the haem from a planar geometry may also be involved, thus complicating this portion of the structural analysis. The use of different probe frequencies to achieve resonance with various electronic transitions, may eventually be of utility in resolving this point.

To summarise, we have shown that within 5 ns of photolysis, the core size in CO-Hb assumes a value closely approximating that in deoxy-Hb in the steady state. The observed Raman peaks for the transient species are slightly shifted from those of *T* deoxy-Hb. It seems possible that this corresponds to a transient core size about 0.02 Å larger than that of *T* deoxy-Hb. However, it is not possible to relate these differences more definitely to structural modifications. Moreover, we cannot yet rule out the possibility that additional changes, perhaps non-monotonic ones, in the spectrum may occur over a longer time scale, yet before the *R*–*T* transition. To investigate the possibility of the occurrence of such movement, we plan to use a double-pulse technique to extend this investigation to a wider range of times. Further, a transient Raman investigation of the entire *R*–*T* transition is clearly called for, making use of the variety of resonances available to probe other vibrational excitations.

We acknowledge the technical assistance of C. L. Castillo in the preparation of the CO-Hb and thank R. G. Shulman for a critical reading of the manuscript, and the authors of ref. 6 for communicating their results before publication.

THE DRUGS HANDBOOK

Paul Turner and Glyn Volans

A dictionary of drugs, arranged in alphabetical order of their medically approved names, with a trade names index. Each entry gives a brief description of the actions, uses and adverse effects of each drug — the sort of information that has been almost unavailable in the non-specialist area of pharmacology until now. Moreover, the book is presented in a concise handbook format to fit easily into a briefcase or capacious pocket. It should prove invaluable to anyone involved in the medical use of drugs.

'Concise, accurate and up-to-date' — Miss W. E. Hector, Senior Lecturer, Queen Elizabeth College, London.

UK Price hardcover £4.95, 0 333 21612 1,
paperback £1.95, 0 333 23655 6.

matters arising

On melting icebergs

HUPPERT AND TURNER'S laboratory studies¹ of ice melt in warm, salt-stratified water, which demonstrate a system of tilted convection layers of melt mixture interleaved with ambient fluid, are useful in focusing research upon the complex phenomenon of iceberg melt but can not be extrapolated so directly to *in situ* Antarctic iceberg melting as the authors have done, for several reasons: (1) density profile data corresponding to the *T, S* profiles of the Weddell Sea station² shown in Huppert and Turner's article are the depth ranges (and the corresponding density gradients)³: 30–50 m ($1.6 \times 10^{-7} \text{ g cm}^{-3} \text{ cm}^{-1}$); 50–100 m ($1.5 \times 10^{-8} \text{ g cm}^{-3} \text{ cm}^{-1}$); 100–300 m ($2 \times 10^{-9} \text{ g cm}^{-3} \text{ cm}^{-1}$); laboratory study¹ ($1.6 \times 10^{-3} \text{ g cm}^{-3} \text{ cm}^{-1}$); as the mean density gradient has a major influence on the vertical scales of free convection it is difficult to see how laboratory results can describe the oceanic iceberg case where this parameter is from 10,000 to 1,000,000 times smaller. In fact, the density difference over the typical 1 cm vertical scale of a single layer in the laboratory study is six times larger than the total difference in density from 30–150 m of the Central Weddell Sea station. (2) At the 23 °C temperature of Huppert and Turner's salt-stratified laboratory experiment, the thermal expansion coefficient is $0.17 \times 10^{-3} \text{ g cm}^{-3} \text{ }^{\circ}\text{C}^{-1}$; in typical Antarctic waters it is 0.05×10^{-3} , less than one-third as effective in controlling density changes relative to the saline contraction factor which is much the same in both cases (0.81×10^{-3} as opposed to $0.76 \times 10^{-3} \text{ g cm}^{-3} \text{ p.p.t.}^{-1}$, respectively). Furthermore, ambient water temperature in Antarctic water is only about 2 °C above freezing point, an order of magnitude different from their laboratory case. The overall thermal effect on density is then between one and two orders magnitude less in the Antarctic situation.

(3) Antarctic icebergs contain some 7% by volume of compressed air^{4,5}. Effects of air bubble release with melt water at depth are unknown but must be important in modifying vertical convection and horizontal heat diffusion across the boundary layer. A characteristic hissing sound has been reported near icebergs (Seelye Martin, personal communication).

(4) The tilted convection layers observed by Huppert and Turner occur at vertical increments of 1 cm and $2.5 \times 10^{-3} \text{ g cm}^{-3}$ density difference. It required the available heat in 3.5 g ambient fluid to melt 1 g of ice; complete mixing would

result in a mixture of density about $5.6 \times 10^{-3} \text{ g cm}^{-3}$ less than that of the ambient fluid supplying the heat. The characteristic vertical scale of layers ought to have been >2 cm; it was not, which indicates that some melt heat was supplied by means other than turbulent diffusion, such as, double-diffusion. In the Antarctic iceberg case, for reasons (1–3), turbulent diffusion should dominate over other transfer mechanisms. While field measurements are lacking, data reported by Matthews and Quinlan⁶ for Muir Inlet, Alaska, showed that late winter modification of the bay water by glacier melt followed a 21:1 ratio. The ambient fluid at 3 °C and 31‰ salinity supplied about 96 cal g^{-1} of icemelt and part of this must have been needed to raise the ice temperature to melt point. Thus from the only available field data it seems that ice melt entrains ambient fluid with a ratio governed at a minimum by the heat available through complete mixing with ambient fluid, and not less as in the laboratory results¹.

(5) Step structure observed in Central Weddell Sea profiles cannot be described as a plausible extension of the laboratory results. The thickest layer in the given profile extends from 100 to 200 m with a total density difference of $2 \times 10^{-5} \text{ g cm}^{-3}$; a 1,250:1 mixing ratio is required to alter 1 g of melt water to ambient fluid density during its rise through this vertical distance, and the 2,250 cal of available heat in the entrained fluid far exceeds that needed for melting.

A plausible extrapolation of the laboratory results of Huppert and Turner to the melting iceberg would state that the berg generates one such convective layer. A single cell convection was the basis of my earlier study³ on upwelling by icebergs. Even so, the existence of low horizontal temperature and vertical density gradients, compressed air bubbles in glacier ice and reduced thermal expansion effects, and velocity shear associated with berg motion severely limit the role of double-diffusion in iceberg melting (an exception might be the melting process of the bottom surface of the berg).

Kerogen maturation and petroleum generation

UJJIÉ¹ concluded that a one-point reversal in the C–H–O maturation pathway of kerogens of the Cretaceous of the Douala Basin indicated that a large amount of hydrocarbons was released from the kerogen. Other interpretations are possible. The basic problem is whether the anomaly reflects hydrocarbon release from similar kerogens, or indicates a change in the dominant kerogen type. The latter interpretation is appealing for three reasons.

(1) The anomalous point is not (*h*) which lies directly on the projections of the maturation pathways defined by the shallower points (*a–f*) and the deeper points (*i–n*). The anomalous point is (*g*) which has higher C and H and lower O contents than adjacent points. The kerogen at (*g*) is near peak oil generation². If the original kerogen types at (*f*) and (*g*) were essentially identical, the H content of the kerogen should be decreasing with depth, not increasing³. The increase in H content with depth from (*f*) to (*g*) indicates an increasing hydrocarbon generating capacity with depth, and suggests a corresponding change in original kerogen type.

(2) By themselves, the C–H–O relationships between points (*f, g, h*) could be interpreted as primarily CO₂ generation from (*f*) to (*g*) and hydrocarbon generation from (*g*) to (*h*). This explanation is unlikely. Pyrolysis experiments indicate that CO₂ generation is greatly diminished by the time significant hydrocarbon generation begins⁴, as it has at (*f*). In addition, thermogravimetric analyses of the (*f*) and (*g*) kerogens indicate that (*g*) had a 50% greater weight loss at 500 °C than did (*f*). If (*f*) lost CO₂ and reached the composition of (*g*), the weight loss differential would be in the opposite direction.

(3) Kerogen is extracted organic matter. Its C–H–O contents should be identical at the same stage of thermal alteration whether the generated products remained in the kerogen in the subsurface or whether they were released in the subsurface. By itself, kerogen analysis yields no information on hydrocarbon release.

UJIIÉ REPLIES—The Cretaceous kerogen of the Douala Basin is the best material available to provide a corroborative evidence of my hypothesis on the reversal in the C-H-O maturation pathway of kerogen, because the Cretaceous is composed of the thick argillaceous sedimentary series in which the original organic matter is identical throughout the whole cores taken between 700 and 4,000 m in depth^{1,2}.

Jones concluded that the anomalous point (g) had a different type kerogen. A series of geochemical studies on the organic matter of the Douala Basin indicates the same kind of organic matter provided in the sample (g) as in the other ones¹⁻³. Tissot *et al.*⁴ pointed out that the whole evolution path of these kerogens is the typical example of their 'type III'.

In order to examine the original kerogen type the maceral components of kerogen should be discussed, instead of the minor difference of hydrogen content and weight loss by pyrolysis as was stated by Jones. The maceral component of each kerogen of the Douala Basin almost consist of more than 80% of amorphous organic cement optically close to vitrinite¹, indicating the homogeneous components throughout the whole cores. Therefore, the C-H-O component path from (g) to (h) should be explained by a large amount of hydrocarbon release, not by the difference of original kerogen type in (g).

Kerogen is extracted organic matter. Its C-H-O content should be related to what kinds of the generated products are released from it, if the original kerogen is identical throughout the strata. The same reversal in the C-H-O maturation pathway as shown from (g) to (h) in the Douala Basin is observed in the Miocene argillaceous sediments of the MITI Borehole in Northern Hokkaido. Examination of hydrocarbon-generating capacity by pyrolysis supports that the relative decrease of carbon content is due to the hydrocarbon release in the MITI Borehole samples (data to be published elsewhere). Therefore, kerogen analysis could give us much information on petroleum generation. To determine whether my hypothesis is applicable to the Douala Basin, the most important work to be done is to decide whether the weight loss by pyrolysis at (g) is due to the generation mainly of hydrocarbon or mainly of CO₂ and/or H₂O.

Stability problem of Kirkwood Gaps

KIANG noticed¹ the importance of the Kirkwood Gaps (particularly the Hecuba Gap) in contrast to Hilda Group in the asteroidal distribution problem, and presented a solution to this problem using a stability criterion inherited in Hill's equation which, he assumed, clarifies the difference between gaps and groups (less populated against populated regions). His discussion, however, discloses the curious fact that he has omitted the first two terms in RHS of his (linearised) variational equation (6), without any convincing ground. This omission causes a critical deviation from the original problem.

Kiang's discussion starts essentially from the canonical equations of motion with one degree of freedom,

$$\frac{dx}{dt} = F_y \quad \text{and} \quad \frac{dy}{dt} = -F_x \quad (1)$$

where the subscripts refer to the partial derivatives with respect to the variables x and y , respectively. Let $x(t)$ and $y(t)$ be periodic. Then he deduces the variational equations,

$$\left. \begin{aligned} \frac{d\xi}{dt} &= F_{yx}\xi + F_{yy}\eta \\ \frac{d\eta}{dt} &= -F_{xx}\xi - F_{xy}\eta \end{aligned} \right\} \quad (2)$$

where ξ and η are the virtual variations to x and y coordinates, respectively.

He insists that from these variational equations he obtained a second order differential equation of Hill's type. Curiously enough, however, the system of equations (2) can be solved by quadrature as will be seen by equations (9), as it has a (variational) energy integral (see also ref. 2)

$$\mu \equiv F_x\xi + F_y\eta = c_1 = \text{constant} \quad (3)$$

This μ is a variation across the orbit. We also have a variation along the orbit by a form,

$$\nu \equiv F_y\xi - F_x\eta \quad (4)$$

which is perpendicular to μ direction. The differential equation for ν can be obtained by a straightforward manipulation as follows:

$$\frac{d\nu}{dt} = (A\mu + B\nu)/D \quad (5)$$

where

$$\left. \begin{aligned} A &= (F_{xx} - F_{yy})(F_x^2 - F_y^2) + 4F_{xy}F_xF_y \\ B &= -2F_{xy}(F_x^2 - F_y^2) + 2(F_{xx} - F_{yy})F_xF_y \\ D &= F_x^2 + F_y^2 \neq 0 \end{aligned} \right\} \quad (6)$$

On the other hand, we see

$$\frac{dD}{dt} = B \quad (7)$$

Therefore, we can obtain the solution for ν by quadrature, considering that μ is given

by equation (3),

$$\nu = D[c_2 + c_1 \int_0^t D^{-2} A dt] \quad (8)$$

c_2 being another constant. The solutions for ξ and η are readily given by

$$\left. \begin{aligned} \xi &= c_1 F_x D^{-1} + F_y [c_2 + c_1 \int_0^t D^{-2} A dt] \\ \eta &= c_1 F_y D^{-1} - F_x [c_2 + c_1 \int_0^t D^{-2} A dt] \end{aligned} \right\} \quad (9)$$

Note that the solutions by quadrature do not include a new period as in the case of Hill's equation, although the solutions include the mixed secular term, $t \times$ (periodic term) in general. This situation comes from the change of period according as different energy constants (the energy difference being c_1).

Kiang's argument is totally wrong in the point: he only took into account some of the necessary terms without any convincing ground, so that the equation becomes the Hill's type. In reality, the variational equations (2) can be solved by quadrature, because the system has an energy integral. There is no need to introduce a transcendental method, or a new period. In other words, the stability criterion, with which he wanted to clarify the difference between Hecuba and Hilda cases, is not inherent in the variational equations (2) *ab initio*. Thus the problem is still open.

2. Diliberto, S. P. in *Contribution to the Theory of Non-linear Oscillations* Vol. 1 (ed. Lefschetz, S.) 1-38 (Princeton University Press, 1930).

KIANG REPLIES—Aoki's attitude is the conventional one and is responsible for the lack of success in solving the Kirkwood Gaps problem so far. He apparently believes that because he could write down the solution of the basic equations by the classical method, there is no need to introduce other methods. But the classical method is, in principle, incapable of solving the problem at hand, because it always leads to results (see, for example, Aoki's equations 9) that apply to all resonances equally—it can never explain the Hecuba-Hilda difference. Hence I regard it highly desirable to introduce some new method, equivalent to more or less radical departures from the classical method. Some modification to explain the Hecuba-Hilda difference within the frame of the simplest gravitational model is necessary but as to the form of modification I adopted in my paper, I made it clear that there may well be grounds for improvement. I do not expect any improvement that I could give here to substantially alter the result obtained.

Stress Free Anaesthesia

Analgesia and the Suppression of Stress Responses

Edited by C. Wood

September 1978, vii + 89pp., £5.00/\$10.25 0.12.763350.2 (Academic Press) 0.8089.1135.x (Grune & Stratton)

Proceedings of an International Symposium held by the Janssen Research Foundation at Beerse, Belgium on 10 February 1978.

Contents

Recent experience with fentanyl. Chairman's remarks. The pharmacology and pharmacokinetics of fentanyl. Reduction of obliteration of reflex responses to surgery. Analgesia and the metabolic response to surgery. Attenuation of stress and haemodynamic stability. Fentanyl-oxygen anaesthesia for patients with mitral valve disease. Haemodynamic influence in deep coma in man of equianalgesic doses of morphine, fentanyl and sufentanyl. Effects of neuroleptic anaesthesia on haemodynamics and post-operative respiratory function in patients undergoing minor and major vascular surgery. Stress in neuroleptic anaesthesia and electrostimulation. Analgesia and muscle relaxation. Moderate doses of fentanyl by infusion for intraoperative analgesia. Effects of high doses of fentanyl in comparison to electrostimulation. Analgesic effects and side effects of fentanyl in man. The use of certain morphinomimetics in acute clinical situations. The effects of anaesthesia and surgery on B- and T-lymphocytes. Immunological aspects of anaesthetic practice.

General discussion

Chairman's summing up.

Perimeters of Social Repair

Proceedings of the Fourteenth Annual Symposium of the Eugenics Society, London 1977

edited by W. H. G. Armytage and John Peel

October/November 1978, x + 158pp., £8.80/\$18.25 0.12.062750.7

This volume records the Proceedings of the Fourteenth Annual Symposium of the Eugenics Society, which was held to assess the impact of current programmes of social repair, or, in other words, those acts of professional intervention designed to remedy or alleviate the failure of natural social processes book, which presents the views of a wide variety of acknowledged experts, and avoids, by this diversity, any insistent personal view. It attempts to unravel the myths and dilemmas of social repair as a first step towards establishing better systems of education, health service and social organisation generally.

Proceedings of the Sero Symposium, Volume 17

Obesity in childhood

edited by E. Cacciari, Z. Laron and S. Raiti

September 1978, viii + 248pp., £10.40/\$21.50 0.12.154150.9

Obesity is one of the major health problems today in wealthy developed countries, not only because of the difficulties involved in therapy but also because of the associated problems of changes in endocrine-metabolic functions and cardiovascular disorders. Some of the physiological factors responsible for self maintenance of obesity, for example alteration of the adipose tissue, are thought to originate in early childhood. The purpose of this symposium was to re-examine some recurrent topics such as long-term therapy and the psychological problems of the obese child. Contributions include the experiences and research results of experts from all over the world.

Methods in Microbiology Volume 10

edited by T. Bergan and J. R. Norris

October/November 1978, xvi + 386pp., £17.80/\$36.75 0.12.521510.x

Interests in the factors controlling the spread of pathogenic bacteria in both human and animal population has led, in recent years, to the development of various techniques for the characterisation of isolates from epidemics. These take many forms. Biochemical tests, serological analysis, phage and bacteriocin typing are particularly important. Volumes 10-13 of *Methods in Microbiology* collect together, for the first time, the methods used in identifying all major human and animal pathogenic bacteria of epidemiological importance. The attention to practical detail will enable the methods to be followed in the laboratory, and it is hoped that this will lead to increased uniformity of method around the world.

Photosynthetic Oxygen Evolution

edited by H. Metzner

October 1978, xvi + 532pp., £18.00/\$37.25 0.12.491750.x

The book is a collection of the papers presented during the Symposium "Photosynthetic Oxygen Evolution" held at Tubingen in September, 1977. Photosynthesis specialists, photochemists and electrochemists have contributed towards this multi-disciplinary discussion of the problems of light-induced oxygen evolution. Dealing mainly with the energetics and mechanisms of light-induced charge transfer reactions in green plant cells, the papers include discussions on how plant cells can create a strongly oxidising power; how the oxidised donor regains its missing electrons; and the role of organically bound manganese in the charge transfer. There are also sections on the structure and ontogenetic development of the oxygen producing system of the chloroplasts.

reviews

Wright's late works

Alan Robertson

Evolution and the Genetics of Populations. Vol. 4: Variability within and among Natural Populations. By Sewall Wright. (University of Chicago: Chicago and London, 1978.) \$46.90; £26.25.

VERDI wrote *Otello* when he was 73 and completed *Falstaff* at the age of 80, though twenty years earlier he had produced some minor works like *Trovatore* and *Rigoletto*. Sewall Wright, though he had contributed extensively to the scientific literature since 1915, published his first book, the first volume in this series of four, in 1968 at the age of 78 and the final two have now appeared in quick succession. The first laid the biometrical and genetic foundations and the second, almost entirely theoretical, extended these to the population level in terms of gene frequencies and concluded with a section on quantitative genetics. The third volume was to discuss the evidence but while the first two were being written so much new evidence became available that it has now become two—the first dealing primarily with evidence from laboratory experimentation and the present one with that from natural populations. The new information came mostly from two new techniques. The first of these, starch gel electrophoresis, has not only produced a great deal of information for the study of population structures (as can be seen from the present contents of journals like *Evolution*) but also answered a previously unanswerable question: What proportion of loci are segregating in wild populations? (the answer is, however, restricted to those loci specifying peptide chains). The second kind of information, from amino acid sequences, can provide a direct genetic measure of the rate of evolutionary substitution at such loci.

Wright's general approach in these final volumes is to analyse specific papers in some detail (sometimes with a re-analysis of his own). For instance, he deals with some work from the early days of genetics like that of Castle on hooded rats (Wright was a junior author of the paper in 1916) and Sumner's work on *Peromyscus*, but also discusses repetitive sequences in DNA and treats extensively the evidence from biochemical polymorphisms in American *Drosophila* populations from Ayala and his colleagues. The volumes

form a valuable reference work and provide a source of critical discussion.

Wright is the last of the three exponents of mathematical studies of evolution made up of himself, Fisher and Haldane, and the final chapters give his summing up of the present situation. The three, working almost independently over about forty years, were very different in temperament and in training. Fisher and Haldane had degrees in mathematics from Cambridge and Oxford, respectively; Wright had a degree in Zoology from a small mid-Western college and continued his experimental work with guinea pigs until he retired from Chicago. Nevertheless, he has always shown extraordinary mathematical insight in solving the problems that he encountered. In fact, a paper of his in 1915 may be considered as foreshadowing the invention of analysis of variance.

He has, I think, always felt that his ideas suffered from a simplistic representation by Fisher and his colleagues. I remember him saying once that "The position got complicated by the appearance of another person in the argument, with the same name as myself but holding completely different views". He felt himself saddled with a naive outlook about the importance of sudden reductions in population size leading to "genetic drift". He was a little surprised to have some British authors scorn "classical random drift" while espousing the "founder principle" which he thought of as a special case of the former. "While it is useful to make such distinctions, it is evident that most of those who have done so have failed to grasp the general principle of effective size in relation to random drift". When Mayr made his criticism of "bean bag genetics" at Cold Spring Harbor in 1959, Haldane felt it necessary to write in reply; Wright did not, he had always taken a more sophisticated view. He returns to the differences in approach on page 464 of the final volume. "It is sometimes supposed, following Mayr (1959), that the early mathematical studies of evolution under Mendelian heredity by Haldane, Fisher and myself were all essentially equivalent, being based on the same simplified biological premises: populations almost homogeneous with respect to an array of

'wildtype' genes except for rare favourable mutations, fixed one at a time, by mass selection, the model referred to by Mayr as 'bean bag' evolution. Actually the processes on which we put major emphasis [Haldane on the basis of major mutations; Fisher on the basis of multiple, largely minor mutations; Wright on the basis of local peak-shifts among interaction systems] were about as different as possible, under the common assumption of Mendelian heredity. Each, however, might be valid for particular characters under particular conditions in species with particular population structures".

His view of the importance of periods of small local population size was not so much that this could of itself lead to fixation in a species but rather that, in an interacting system, such chance changes in gene frequency could allow the population to move, as a consequence of the subsequent selection, from one adaptive peak to another. As with all models involving interactions between many loci, it is not amenable to direct algebraic treatment and Wright's approach has been mainly verbal, dealing numerically with specific examples.

In the past decade the old arguments took on new life in the 'neutralist-selectionist' controversy about the mechanisms of the maintenance of genetic variation within populations (the evidence coming mostly from electrophoresis), and about the rate of gene substitution in protein evolution. Ironically, the neutralist view corresponded somewhat with the more simplistic versions of his views which he had rejected so indignantly in the 1930s. From his discussion on both these points, it is clear that he is in essence a 'selectionist', though he is writing before the recent findings that modifications of electrophoretic technique could increase greatly, at least for some loci in *Drosophila*, the number of alleles known to be segregating in populations.

The fascination of these final volumes comes from the breadth of historical perspective: for the greater part of the development of modern genetics, Wright was really there. □

Alan Robertson is a Professor in the Department of Genetics at the University of Edinburgh, UK.

Metal sulphides

Mineral Chemistry of Metal Sulfides. By D. J. Vaughan and J. R. Craig. Pp. 493. (Cambridge University Press: Cambridge and London, 1978.) £19.50.

METAL SULPHIDES are not only of concern to geologists in economic, petrological and sedimentological fields but also to metallurgists in many specialisms from the extractive industries to electronics. This book aims to lead all such workers through a variety of experimental and theoretical approaches into a clearer understanding of the range of natural and synthetic sulphides. The authors have made individual contributions to sulphide research and now they have assimilated a vast literature to produce a concise and balanced book.

The text and appendices contain an immense amount of well indexed data with generous references to original work; this will therefore be a satisfying handbook to investigators, but not a manual of experimental techniques. Vaughan and Craig, however, seem to have had the additional objective of teaching the willing reader who might be ignorant of one or other of the particular subjects covered, from crystal chemistry to determinative

methods. In the introduction and elsewhere the underlying theory is introduced straightforwardly and without condescension.

Only four years after P. H. Ribbe's *Short Course Notes* on sulphide mineralogy (Mineralogical Society of America, 1974) it may be asked "why another publication on the same ground?". Although the aims and constraints are here somewhat different, one answer might be that Ribbe showed it could be done. Until that date the variety and complexity of the sulphides defied condensation; their classification was never as straightforward as that of the silicates, and only with the recent deployment of crystal chemistry to the explanation of sulphide structures has a more satisfying rationalisation been glimpsed. Sulphosalts will perhaps be the last to emerge from the jungle but anyone concerned with these not necessarily rarer variants will still have to rely on the reviews of Ribbe's contributors, as Vaughan and Craig dismiss them entirely in order to limit the size of their text.

Naturally this volume is altogether more polished. On the whole, it parallels the 1974 book on sulphide crystal chemistry and classification, with some later work to 1977 included,

and also on chemical bonding, principal phase equilibria of sulphides and associated experimental methods, and current trends and prospects in the investigation of natural sulphides in geology.

Part of the distinctive trend of the book is found in the balancing chapters on electrical and magnetic properties and their applications, spectroscopic studies, classical (that is, including microscopic) determinative methods and sulphide thermochemistry. The chapter on sulphide equilibria in aqueous solutions leads to consideration of conditions in natural hydrothermal fluids and to the thermodynamics of sulphide solubility and deposition.

The final chapter discusses natural sulphides and recognises their differences from the pure and synthetic in their major, minor and trace element contents, solid solution phenomena and S-isotopic variation, the study and significance of all of which are introduced. Appendices contain mineralogical data on 319 sulphides, univariant sulphidation data and invariant points in sulphide mineral systems.

Heterogeneous catalysis

Dynamic Heterogeneous Catalysis. By K. Tamaru. Pp. 140. (Academic: London and New York, 1978) £8.50.

IT is difficult to know for whom this volume is intended. Its objective is to emphasise that an understanding of heterogeneous catalysis cannot be achieved by studies of the equilibrium states of solid/gas systems, but must be based on a study not only of the kinetics of catalysed reactions but also of the changes in adsorption on, and chemical properties of, the catalytic sites under working conditions. This thesis is widely accepted and has indeed been the objective of much research, particularly by the author and his coworkers. The complementary view, that one must first understand the nature of clean surfaces and their interaction with simple gases, is, however, implied by a great deal of recent work using modern techniques of surface physics, so that an attempt to strike a balance between the two would be timely.

One therefore expects this to be a research monograph. Instead, one finds a very uneven text including a great deal of elementary physical chemistry (for example, kinetic derivation of the

Langmuir isotherm, Langmuir-Hinshelwood kinetics, and a discussion of homogeneous gas reactions) with which the average research worker in the field will be very familiar. Yet the presentation is not sufficiently balanced to serve as a supplementary undergraduate text. The descriptions of various surface physics techniques—FEM, FIM, LEED, ELS, AES and PES—are very sketchy and hardly seem justified as only scant reference is made to them later in the book: again the research worker in this field will already be very familiar with these techniques.

The book consists of four chapters on: general reaction kinetics; adsorption; the kinetics of heterogeneous reactions; and the applications of spectroscopic techniques to the dynamic treatment of adsorbed species in reaction conditions. Only in the last chapter, in which the examples are drawn largely from the author's own work, does the main theme of the book begin to dominate.

Libraries carrying a comprehensive collection on catalysis will no doubt wish to have this book, but it is unlikely to attract a wide readership.

NEW

***CELLULAR
DEGRADATIVE PROCESSES**

R. T. DEAN

Outline Studies in Biology

Components of cells in all living organisms undergo continual breakdown and resynthesis. The specialized mechanisms involved in these degradative processes are discussed, together with their integration and control. Emphasis is placed on the universality of these mechanisms and their importance in the dynamics of cellular activity. Limited degradation is given full coverage.

July 80 pages Illustrated

Paperback 0412151901 £1.75

***HUMAN GENETICS**

J. H. EDWARDS

Outline Studies in Biology

This book aims to provide a basic introduction to the mechanisms of heredity and to the ways in which these mechanisms may fail and thereby lead to disease.

In general, the approach is mechanistic and deductive, emphasis being placed on the necessary consequences of the self-reproducing and self-copying genetic elements which we may regard as being known to exist. The book touches on many controversial topics including genetics and intelligence and the problems associated with pre-natal diagnosis.

***HUMAN EVOLUTION**

B. A. WOOD

Outline Studies in Biology

This up-to-date account of human evolution critically interprets the wealth of newly discovered fossil material; in particular that evidence which provides a greater understanding of the adaptation and behaviour of the early hominoids. Current theories on human evolution are discussed, as are controversies concerning the nature of the first hominids, the emergence of *Homo*, and the probable place of australopithecines in the evolutionary process.

**ANCIENT SEDIMENTARY
ENVIRONMENTS**

and their Subsurface Diagnosis *Second Edition*
R. C. SELLEY

The accurate diagnosis of ancient sedimentary environments, by comparison with modern deposits, is of increasing importance in the search for oil, gas and other economic materials. This text shows how to identify the depositional environment of ancient sedimentary rocks, summarizing the conclusions of a large and rapidly expanding field, and using case histories to illustrate these conclusions.

METHUEN 

**PERCEPTIONS
AND REPRESENTATIONS**

The theoretical basis of brain research and psychology
KEITH OATLEY

The theme of this book is the explanation of behaviour in terms of the workings of the brain, an instrument far more complicated than any computer. The author believes that we need theories that help us to understand how the brain allows us to interpret and attribute meanings to events. In pursuance of this belief he gives an account of such problems as to how the brain copes so well with incomplete sensory data and with damage to its own components.

Statistics for Experimenters: An Introduction to Design, Data Analysis, Data Analysis, and Model Building

by G.E.P. Box and W.G. Hunter,
both of the University of Wisconsin,
and J.S. Hunter, *Princeton University*.

Provides scientists, social scientists and engineers who have little or no statistical background with the knowledge necessary to design experimental programs of high statistical, scientific, and engineering efficiency. It introduces the philosophy of experimentation and the role that statistics plays in experimentation. Examples drawn from actual case studies are used. Pesticides: Preparation and Mode of Action

by R.J. Cramlyn, *Principal Lecturer in Organic Chemistry,*
The Hatfield Polytechnic, Hertfordshire.

Discusses the general principles of underlying chemical pesticides, with a brief history of their development. It lists the main types of insecticides, herbicides, and fungicides, with a discussion of their chemical preparation, uses, and biochemical mode of action. Acaricides, nematocides, fumigants, molluscicides, and rodenticides are also covered, and some novel methods of pest control are discussed, such as use of juvenile hormone mimics, sex attractants, chemoesterilants, and microbial insecticides. The book ends with a discussion of pesticides in the environment and of future development in pest control chemicals.

Ecology of Plant-Parasitic Nematodes

by D.C. Norton, *Iowa State University*.

A broad treatment of the ecology of the nematodes that parasitise plants. The book is not concerned with disease *per se*. It attempts to examine one small facet of a group of organisms that, under some conditions, cause disease or damage. The author collates what is known of plant nematode ecology, using extensive documentation as building blocks for knowledge of the ecosystems. Nematodes are treated as animals in their natural habitat, and not only as plant pathogens or parasites.

Practical Fungal Physiology

by P.M. Robinson, *Department of Botany,*
The Queen's University of Belfast.

Essentially a practical book which describes the use of fungi as tools for physiological experiments. The pattern of development of mycelial fungi is traced from germinating spores to mature hyphae and finally to the formation of the typical fungus colony. Instructions are given for a range of experiments which relate to each stage in this developmental sequence. Other topics of general mycological interest are dealt with and include reproduction, nutrition, morphogenetic substances, staling, mycostasis and continuous culture. Most of the practical details are given as flowsheets but additional information and hints are interspersed with a series of short essays on the selected topics.

Understanding living systems

Ordre et Dynamique du Vivant: Chemins de la Biologie Moléculaire. By A. Danchin. Pp. 381. (Editions du Seuil: Paris, 1978.)

THE object of this book, as specified by the author himself, is to emphasise the contribution of our knowledge of molecular phenomena to the understanding of a living system as a whole, including the human brain processes. The book opposes those theories which purport that our understanding of the way a whole organism is working is a specific property of the system and cannot result from the analytical study of each of its components, and concludes that the fundamental properties of a living system are the direct consequences of the properties of its constitutive molecules.

The author chooses several "reduction levels". He first examines the general characteristics of a cell and the modalities of its development. He then considers a second reduction level, the chromosomal one, and includes the rudiments of genetics and indispensable notions on cellular division. In the third and most extensive part, he comes to the fundamental reduction level, the molecular one. After recounting the nature of the interactions between atoms and between molecules, he gives a clear account of the processes of molecular biology—that is, an account of the mechanism of protein synthesis and its regulation—and has succeeded very well in describing the basis of these processes clearly and concisely.

The last part is the most original. It begins with an examination of the nature of viruses and an analysis of the possibility of their synthesis, continues with a study of genetical manipulation experiments already accomplished or to be considered in the future, and ends with an examination of the feasibility of hypotheses concerning the origin of life and the evolution of species. He explains the relationship between phylogenesis and variations in the amino acid sequences of proteins and why he conceives the evolution of species as the development of controls: some fluctuations in the hereditary programme favour the adjustment of the system to external conditions and are therefore integrated in the descendants. There must be a limit, however, to what can be recorded in a genetical programme, and non-hereditary modifications will occur. These individual processes, which the author calls epigenesis, allow adjustment to the external medium. The epigenesis of the nervous network is given as a good example.

This book is aimed to non-specialists. My main regret is that the author's care in explaining clearly the physicochemical mechanisms of the biological processes to non-initiates did not allow him to develop his own ideas more extensively. Nevertheless, this interesting book succeeds well in its stated purpose of showing that the working

of living systems can be explained by the behaviour of their constitutive molecules and their appearance by physicochemical phenomena.

J. Tonnelat

J. Tonnelat is Professor of Physicochemical Biology at the Université de Paris-Sud, Orsay, France.

Regulators of plant growth

Natural Plant Growth Inhibitors and Phytohormones. By V. I. Kefeli. Pp. 278. (Junk: The Hague and Boston, 1978.) Dfl.90; \$44.

THE known and accepted hormonal regulators of plant growth and development comprise the auxins, the gibberellins, the cytokinins, abscisic acid and (perhaps) ethylene. Each of these substances has a clearly defined range of physiological activities, and it is the interplay of these activities which results in the coordination and regulation of the various processes and development. Some plant physiologists, however, believe that this is not enough, asserting that the precise regulation of a process may only be achieved through a balance between stimulatory and inhibitory actions. Given this premise, it is inescapable logic that the auxins, gibberellins and cytokinins, whose actions on cell growth and differentiation are predominantly stimulatory, should be balanced by endogenous, growth-inhibitory substances. As almost any substance, at sufficiently high concentration, will inhibit plant growth, it is obviously very easy to find such inhibitors; it is, on the other hand, and equally obviously, extremely difficult to prove that such growth-inhibitory substances actually act, endogenously, to inhibit growth. Dr Kefeli is a protagonist of the inhibitor camp, and he uses this book in a forceful and single-minded attempt to convince the reader that his view is correct.

The book is based on the author's work carried out at the Timiryazev Institute of Plant Physiology of the USSR Academy of Sciences between 1961 and 1967, and its most valuable contribution lies in providing, for Western scientists, in English, a readable and well documented summary of work which is not easily available from published literature. It is also useful in bringing together diverse information on the synthesis and hypothetical functions of growth-inhibitory substances.

There are, however, many shortcom-

ings. The background literature is only referred to when the conclusions favour the case being made. Also, doctrines which are currently under question in the West (for example, the Cholodny-Went theory of tropisms, the gene expression theory of phytochrome action, and the presumed control of transcription by auxins and gibberellins) are presented as established fact. Critical analysis of data is practically non-existent. This book seeks to make a case, not to present a reasoned and unbiased account. Thus, only the reader himself can judge whether it is successful. Personally I remain unconvinced.

H. Smith

H. Smith is Professor of Plant Physiology at the University of Nottingham, UK.

newly on the market

Laser microprobe. Zeiss-Jena. The Laser Microprobe from Zeiss-Jena can carry out qualitative micro tests on almost any electrically nonconductive and conductive specimen, and requires only a very short time for sample preparation. Microanalysis can immediately follow the usual microscopic examination of the sample under the laser microscope. Semiquantitative microanalysis is also possible. The use of TV type spectrochemical detectors enables the immediate teledisplay of the spectrochemical composition of the sample spot vapourised by the laser microscope.

Circle No. 52 on Reader Enquiry Card.

Laboratory power supply. Buchler. A laboratory power supply featuring an L.E.D. digital display, has been introduced by Buchler Instruments. The display shows watts, milliamperes or volts, and can be easily read. Maximum outputs are 1,000 V, 200 mA and 200 W. The unit can operate in either a constant-voltage, constant-current, or constant-power mode, instantly selected by pushbutton. Overvoltage and overcurrent protection are built in. The unit is particularly designed for the needs of workers in research and clinical electrophoresis. Voltage and current regulation are 0.1% and 0.2%, respectively.

Circle No. 53 on Reader Enquiry Card.

Solid state digital store. Wayne Kerr. Wayne Kerr have introduced the ADS1 solid-state digital store to complement their RA200 AF response analyser. The RA200/ADS1 provides a continuous response curve, continuously updated with no chance of missing a sharp spike at some point, and no internal filters or integrators to distort the response pattern. Whether the signal source is the built-in sweep oscillator, or a gliding-tone test tape or disk, the dBs can be read from the vertical scale and frequency from the logarithmic horizontal scale. The solid-state digital store will record up to four complete curves and retain the information (with the RA200 switched off) for 2 weeks.

Circle No. 54 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Form.

Refractometer. Reichert-Jung. The Reichert-Jung Abbe Brix refractometer produces consistently accurate results even when used by an unskilled operator. All readings are presented on a L.E.D. digital readout, eliminating scale interpretation errors and enabling group observation. Three modes of measurement are provided by a mode selector switch. Temperature measurement is performed at the prism/sample interface and displayed digitally to 0.1 °C.

Circle No. 55 on Reader Enquiry Card.

The Reichert-Jung Abbe Refractometer

Spectrophotometer. Erba. The new Carlo Erba UV-vis spectrophotometer, the Spectracomp 601, allows all information to be keyed in through a simple keyboard. The spectrophotometer incorporates a programmable computer, offers custom-made programs of analysis, and gives a clear print-out of all instruments' parameters. It allows statistical analysis of spectral data, incorporates a real time clock and a print-out of time, date and temperature, and graphically displays values of absorbance and transmittance versus wavelength on an incremental plotter.

Circle No. 56 on Reader Enquiry Card.

Two-stage microchannel-plate multiplier. Philips. By incorporating two different microchannel plates in series in one electron multiplier construction, L.E.P. in cooperation with Philips have achieved high gain combined with low gain fluctuation ($\Delta G/G \approx 20\%$). Moreover, the gain can be varied between a value of 10^5 and 5×10^7 while the high resolution is maintained. The two-stage construction can be used as an open amplifier for spectrometry (X rays, UV, charged particles) or incorporated in a photomultiplier tube.

Circle No. 57 on Reader Enquiry Card.

Atomic absorption spectrophotometer. Perkin-Elmer. Perkin-Elmer announces the Model 560, double-beam atomic absorption spectrophotometer. The Model 560's microprocessor includes a new computing ability that makes it possible to do complex calculations and implement sophisticated logic programmes quickly and accurately. Averaging, standard deviation, coefficient of variation and reslope are built-in. A dual-blazed grating permits optimum photometric response throughout the wavelength range with a single grating. The Model 560 features automatic calibration with up to three standards and provides integrated readings in absorbance, concentration or emission intensity, either updated continuously or held on the instrument display. Integration times are 0.2–60 s.

Circle No. 58 on Reader Enquiry Card.

Interferometer. Edinburgh Instruments. The model 200 confocal scanning Fabry-Perot interferometer has a standard free spectral range of 0.025 cm^{-1} and an experimentally obtainable finess of better than 20. The resolution of the instrument is of the order of 0.001 cm^{-1} (30 MHz). Other free spectral ranges are available and an integral (pyroelectric) detector permits a chart record of the spectrum to be obtained.

Circle No. 59 on Reader Enquiry Card.

Low temperature cooler. Oxford Instruments. The K-Tip is designed for areas where there is a requirement to cool a sample or detector down to a temperature of 70 K, without the inconvenience of employing liquid gases. Some of the application areas envisaged include:— remote or hazardous areas where liquid gas supplies are either not available or undesirable; in process control where detectors are required over conveyors or other inaccessible locations; in airborne or mobile systems where low weight, low power consumption and small size are an important consideration; and the sampling of atmospheric pollutants by cryopumping and subsequent GC analysis. The instrument comprises a single stage light-weight cooling head, coupled to a compact compressor package by flexible gas lines.

An Introduction to the History of Virology

A. P. WATERSON and LISE WILKINSON

'This handsomely produced volume covers the progressive unveiling of the nature of the virion and the evolution of the modern concept of a virus. The first page catches the reader's eye by a magnificent colour plate of a bunch of variegated tulips, which has distinctive patterns attributable to an infection by a virus, the tulip mosaic virus. From here onwards the reader will be hooked by the dazzling story of virology (many of the founder fathers are with us still), ably unfolded.'

The Evolution of Sex

J. MAYNARD SMITH

The question of why organisms reproduce sexually is still a matter of controversy. In this account, Professor Maynard Smith considers the selective forces responsible for the origin and evolution of sexual reproduction and genetic recombination, using quantitative population genetics arguments to support his ideas. The author does not claim to solve all the problems he raises, but this clear and well argued account will provide stimulating reading for advanced undergraduate students and research workers in evolutionary theory.

CAMBRIDGE UNIVERSITY PRESS

now you can measure testosterone and dihydrotestosterone separately or together

Our new RIA kit is the simplest and fastest available for the assay of testosterone and dihydrotestosterone, separately or together in research applications in a wide range of biological samples.

To assay both androgens together a high specific activity tritium label gives the assay a very sensitive detection limit of 3 pg dihydrotestosterone per incubation tube. Also, a wide range of concentration levels can be assayed, up to 400 pg testosterone and 800 pg dihydrotestosterone per incubation tube.

Separation of the two androgens is achieved without the need for column chromatography by the use of a novel oxidation step which destroys the testosterone present. The assay of the unaffected dihydrotestosterone is achieved with a simple protocol incorporating a short incubation time of 2½ hours. Standards for both androgens are provided. Accurate results are obtained easily and quickly.

obituary

Michel Magat

MICHEL MAGAT, professor at the Paris-Sud University of Orsay, died on 6 June 1978. He had been for more than forty years one of the notable physical chemists in Europe.

Born in Kharkov in October 1908, he did his first research in Germany with Ernst Bergman (who was to become one of the organisers of chemical research in Israel) before joining the group of Edmond Bauer at the Sorbonne. There some of his publications made him widely known before he had reached the age of thirty. During the war he was with the Free French Forces until 1945. He then spent a long time at Princeton, adding to his already wide range of interests that of polymeric materials and their behaviour under intense irradiation.

After the war he was among those whom Frédéric Joliot—at the time head of the Centre national de la Recherche scientifique—entrusted with the development of French physico-chemical research. Much of what has been achieved since has been due to him and to his many brilliant pupils. Director of research at the C.N.R.S., he later became assistant professor at the Sorbonne, then full professor. When a Faculty of Science was established at Orsay, he was among the first to go there, and contributed greatly to make it one of the liveliest research centres in France.

He always showed a great interest in his teaching, and in coordinating his lectures with those given on neighbouring subjects. In this too he was a precursor of what has since become commonplace. He was one of those who were not afraid to state that doing good research did not always qualify one to be a teacher.

Radiation effects, polymers, molecular collisions, relaxation phenomena, reaction transients, nearly all aspects of molecular spectroscopy, the structure and behaviour of water, liquids and glasses were among the subjects this encyclopaedic man took up with constant success. His principal concern was fundamental research but he kept a keen sense of realities, and a number of his studies have had useful applications. Graduates came to his laboratory from many countries to benefit from his direction. Throughout the world, his many former students kept with their former 'maitre' the ties of friendship, and often looked for the advice and judgment of his experience and

fertile imagination—the more so as he was a true internationalist, always concerned with improving scientific and cultural exchanges, promoting collaborations and cooperations across frontiers, and also across intellectual and political barriers.

Magat had been president of the Société de Chimie physique, which had recently made him its honorary life president. He was also a vice-president of the Faraday Division of the Chemical Society, and a scientific advisor of the Hahn-Meitner Institute in Berlin. His many travels, his remarkable fluency in many languages, his interest in man and his sense of humour also made him a living repository of the world's folklore and jokes.

Many colleagues and friends mourn his death. Michel Magat achieved much in his research and teaching. He was also fully committed to every cause and principle in which he believed. Age, experience, fame and responsibilities had not dulled in him the sense of justice and duty. He had the friendship and respect of all those who knew him.

C. Troyanowsky

W. D. Chesterman

PROFESSOR W. D. CHESTERMAN, distinguished for work on high speed photography and side-scan sonar, died on 6 July 1978 at the age of 65, after a short illness.

After graduating at Bristol University in 1934 he worked in the research department of the British Thomson-Houston Company. In 1939 his industrial experience proved of value to the Admiralty at the Signal School in Bristol and in 1943 at H.M.S. Vernon. In 1945 he was in charge of the Admiralty Photographic and Instrument Research Laboratory and then moved to the Admiralty Research Laboratory, Teddington.

He was much concerned with the development of techniques involving photography and, in a joint study with industry, made a major contribution to the design of a high speed camera. An underwater study, combining theory and experiment (with short period flash and high speed photography), gave an elegant demonstration of the changing forms of transient, but troublesome, cavitation bubbles.

He became a Fellow of the Institute

of Physics in 1943 and of the Physical Society in 1945. Among his early publications was an authoritative book, on the photographic study of rapid events (1951), which proved of wide interest. His leadership was also recognised by his chairmanship of the International Committee on High Speed Photography (1956–58), and by his Fellowship of the Royal Photographic Society in 1958.

Meanwhile, in 1949 he joined the Admiralty Underwater Weapons Establishment, where his restless enthusiasm and drive stimulated the application of side-scan sonar. He made the first extensive true-plan presentation of sea floor patterns, from an overlapping mosaic of records. The scientific value of the method for showing relief and texture in plan view was illustrated in a joint paper in 1958. In 1959 he was awarded a D.Sc. by Bristol University for his pioneering work in several fields.

In 1960 he made a courageous change by taking the Chair of Physics at Hong Kong. Under his stimulating guidance the department grew in size, became interested in the surrounding seas and attracted visits from other workers. His own research included sonar surveys of nearby sea floors as well as banks of the South China Sea. All was new, but of particular interest was his study of patterned coral floors. He also demonstrated the method in Canadian waters.

In 1966 he became head of the Geophysics Group of Bath University and the Chair of Geophysics was created for him in 1969. He built up the group, attracted funds from outside and encouraged interest in acoustics and the sea. He found a ready demand for side-scan sonar surveys of potential under-sea cable routes and sought to improve search and presentation techniques. Although these aims were commercial the data obtained were scientifically valuable. In 1975 he became head of the Physics School and then became Professor Emeritus just before retirement in 1978. He had been an effective member of University Senate and Council.

His humanity, charm and vivid personality won him many friends and made him easy to work with. These qualities, and his use of hyperbole helped to coax opponents into willing helpers and were valuable aids when handling pomposity. He calmed the nervous students at vivas and had the vital gifts of making young researchers

feel significant and of welding them into an effective team. He had a healthy disrespect for unjustified bureaucracy.

He paid many visits to the mountains and was particularly keen on high level walks. His considerable knowledge and love of music was a pleasure to his friends, an asset to the University Music Society and led to a deep involvement in the management of the Bath Festival. He was largely responsible for the creation of the elegant Crafts Study Centre in Bath.

He leaves his wife Jean and two children Merlyn and Patrick.

A. H. Stride

Vivi Laurent-Täckholm

BIOLOGICAL science in general, and Egyptian botany in particular, has suffered a great loss with the passing of Vivi Laurent-Täckholm, who died in Stockholm on 3 May 1978, at the age of 80.

This grand old lady had been closely associated with the University of Cairo in Giza for over 50 years, some 32 years as a professor of botany in the Herbarium. Vivi Täckholm was recognized and respected not only as the 'dean of Egyptian botany' but appreciated by all who knew her as one of those rare scientist-scholars who is completely selfless. She helped countless students and investigators both in Egypt and abroad by giving freely of her vast experience and deep erudition on all matters Egyptian, motivated only by a sincere hope that a more carefully planned research project could be launched, or if a project was near completion, that a more mature complete interpretation could be achieved.

A brief overview of her life reveals Vivi Täckholm as a very unconventional woman. She was born in Djurs-holm on 7 January 1898. After obtaining her fil. kand. degree in botany (embryology) in 1921 at the Stock-holms Högskolas, she travelled to the U.S.A. where she worked from east coast to west coast at various jobs, including being a servant. She also began at that time her career as a writer, with a two volume work illustrated with her own photographs entitled *Vivi's resa . . .* (Vivi's Journey). This was first published in Stockholm (1923-24) and soon after in German translation (Gotha, 1925-26).

After her return to Sweden, she held a position in the editorial department of the *Nordisk Familjebok* (Nordic Family Book) from 1923-26 (and again in 1931-33). From 1923-25 she also worked as a journalist for various

Stockholm newspapers. She wrote the children's classic *Sagan om Snipp, Snapp, Sorum* (The Saga of Snipp, Snapp, Sorum) during that period (published 1926, last reprinted in 1976.)

In 1926 she married Gunnar Vilhelm Täckholm, a promising botanical investigator who had earned his doctorate at Stockholm in 1922 and had already gained a reputation for his cytological work. Gunnar Täckholm was called as Professor of Botany to the Egyptian University in Cairo (founded in 1908) in September 1925 to found a department of botany in the newly established Faculty of Science. For the next three years, Vivi aided her husband with all those duties associated with running the department (housed in the former harem building of the Za'afaran Palace) and taught the practical botany instruction for students of medicine, pharmacy and dentistry.

During those early years the need for an Egyptian flora was greatly felt, and the plans were laid for the monumental, but still unfinished *Flora of Egypt*. Also a number of major field trips were made and extensive botanical material collected. The Täckholms stayed in Egypt until 1929.

Vivi then spent a year and a half at the Herbarium Boissier in Geneva studying and comparing their specimens with the type specimens of *Flora Orientalis*. She would later acknowledge the importance of this period not only for her understanding of floristics and taxonomy but for the stimulation and encouragement gained from Robert Chodat, the eminent botanist-taxonomist. Vivi Täckholm continued work on identification of Egyptian plants in Berlin, Kew, London, Weimar and Stockholm under scholarships from the Royal Swedish Academy of Sciences. She and her husband continued their collaboration until his death from tuberculosis in 1933.

Vivi Täckholm was persuaded to continue the work her husband and she had started. The Botany Department at Cairo, especially the Herbarium, grew and profited by her association. Under difficult conditions she gradually accomplished wonders. Indeed she called herself 'the world's biggest beggar.' Largely through her labour and efforts, the herbarium grew to be one of the largest and finest in Africa; the same is true of its botanical library.

In 1941, 16 years after its inception, volume I of the *Flora of Egypt* authored by Vivi and Gunnar Täckholm, in collaboration with Mohamed Drar was published as a Cairo University (then Fouad I University) bulletin; volumes II, III and IV appeared in 1950, 1954 and 1966 respectively. These later volumes were co-authored by herself and her Egypt-

tian collaborator and friend Drar. When Drar died in December 1964 at the age of 70, Vivi Täckholm expressed her great concern for the future of the Flora project which she continued to work on until her death.

The *Flora*, not unexpectedly, is an unusual work. It is a labour of love, clearly carried out unhurriedly in the tradition of those great botanical scholars she would emulate. It has been hailed as a model of scholarship and completeness. One special feature is the detailed treatment of the extensive ancient Egyptian tomb flora; another is the attention paid throughout the volumes to agriculturally important plants and economic botany. Also the enormous bibliographies, which provide access to the ancient and modern Arabic literature, are gems. Since the completion of the *Flora* would take many additional years, a version especially aimed at students, was published in 1956 (2nd edition 1973).

In 1952 Stockholms Högskolas conferred upon her an honorary doctorate. In April 1978 she was honored by the Royal Swedish Academy of Sciences with the gold Linné medal for her pioneering research. The Egyptian government bestowed her with high order decorations on her 60th and 70th birthdays. A special Festschrift entitled *50 Years Cairo University Herbarium—80 Years Birthday of Vivi Täckholm* was published in 1977.

In addition to several shorter, research publications, Vivi Täckholm authored numerous popular and semi-popular books. In these works her supreme knowledge of Egypt as well as her deep love for plants, Egypt, and the Egyptian people is apparent. Indeed she is attributed with saying she 'could live without food, but not without flowers.'

Cairo University has recently decided to name the Herbarium in her honor. But the greatest legacy of Vivi Täckholm is the tradition of love for work and scholarship that she set for her many students and associates. She was also gifted with an exceptional and gentle personality. All who knew her, well or slightly, agree that they are better off, even enriched, by having associated with her. Her smile, bright eyes, fluffy snow white hair, generosity and readiness to help will be remembered warmly by many. Those who had the pleasure of visiting her at her apartment in Orman will also recall her gracious hospitality.

Her closest survivors, a brother, Professor Emeritus Torbern Laurent, her sisters Maj Laurent, textile designer and Gavonne Laurent, several nieces and nephews, and their families, are extended our deepest sympathies.

In accordance with the provisions of the foundation, papers are herewith invited for 1979 in conjunction with the

HEINRICH-WIELAND-PRIZE

which is endowed by the Margarine Institute for Health Nutrition, Hamburg, for the promotion of research.

The prize, named after Professor Dr. Heinrich Wieland, the Nobel Prize winner who died in 1957, is awarded annually and is offered for work on the chemistry, biochemistry and physiology of fats and lipids, as well as on their clinical importance and their significance in the physiology of nutrition.

The Heinrich Wieland Prize consists of a "Heinrich Wieland plaque" and the sum of 15,000 West German Marks.

The prize-winner will be selected by a Board of Trustees which consists at present of the following:

Prof. Dr. Wolfgang Gerok, Freiburg
Prof. Dr. Rolf Grüttner, Hamburg
Prof. Dr. Werner Heimann, Karlsruhe
Prof. Dr. Dr. Wilhelm Stoffel, Cologne
Prof. Dr. K.-H. Baessler, Mainz
Prof. Dr. Dr. h. c. Gotthard Schettler, Heidelberg
Prof. Dr. Viktor Wolf, Hamburg
Prof. Dr. Nepomuk Zoellner, Munich

Persons eligible for the HEINRICH-WIELAND-PRIZE for 1979 are authors of unpublished scientific treatises or treatises published during the period from 1978 to 1979. Papers must be written in German, English or French. All Papers in English or French must be accompanied by a summary of about 3 pages in German. Treatises that have already been awarded some other prize for scientific work are not eligible.

The closing date for sending in Papers for the 1979 award is 1st March, 1979.

A single copy of the Paper must be sent by this date to the following address:
Board of Trustees for the Award of the Heinrich-Wieland-Prize
Prof. Dr. Alfons Fricker, Ringelberghohl 12, 7500 Karlsruhe-Groetzingen 41,
West Germany.

The presentation of this year's prize will take place at 10.30 a. m. on 27th October, 1978 in the Adolf-von-Baeyer-Lecture-Hall of the University of Munich, which is located in Meiserstrasse.

APPOINTMENTS VACANT

STATE OF KUWAIT — Kuwait University Academic Posts for 1979/1980

Applications are invited for the posts of professors, assistant professors and lecturers. Contracts commence from 1st September, 1979, for two years renewable for a further period of four years if convenient to both applicant and the University.

Applicant should be—

- Holder of Ph.D. degree or its equivalent in the respective specialisation.
- Holder of an academic post at present in an accredited university or research centre.

It should be noted that—

- Teaching in English is a must.
- Method of teaching at Kuwait University is based on the credit system.

Field of specialisation—

- Department of Physics: Solid State Physics, Nuclear Physics, Electronics
- Department of Chemistry: Organic Chemistry, Physical Chemistry, Inorganic and Analytical Chemistry
- Department of Biochemistry: Immuno Biochemistry, General Biochemistry
- Department of Zoology: Comparative Chordate Anatomy, Animal Physiology (Endocrinology), General Zoology
- Department of Geology: Structural Geology, Geochemistry, Recent Sedimentology

Rank and Salary will be determined according to present position, qualification and years of experience

Monthly total salaries are in the range of:

Lecturer (U.S. Assistant Professor)	K.D. 460—550
Assistant Professor (U.S. Associate Professor)	575—665
Professor	665—755

(One K.D. is equivalent to U.S. dollars 3.5. There is no income tax in Kuwait, currency is freely transferable without any restriction.)

Candidates are also entitled to the following privileges:

- Annual return air tickets to the country of citizenship would be provided to the applicant, his wife and three of his children not exceeding the age of twenty.
- Free furnished accommodation with water and electric supplies.
- Excess baggage allowance in the vicinity of 30 (thirty only) kilograms for the staff member and 20 (twenty only) kilograms for each member of his family shall be incurred by the University, provided these members accompany him upon his joining the service.
- The staff member shall be entitled to free sea freight allowance of 400 (four hundred only) kilograms, provided costs of the said freight for the said cargo do not exceed Kuwaiti Dinars 100 only. This is applied at the beginning and end of the contract.
- Gratuity at the end of service shall be one month's basic salary for each year spent in the service of the University.

Application and Curriculum Vitae forms are obtainable from the nearest Kuwait Embassy. Completed application accompanied by three letters of recommendation, together with a non-returned copy of the candidate's publications should be submitted directly to Kuwait University, Department of Administration Affairs, P.O. Box 5969, Kuwait, not later than 31st December, 1978. Short term contract (e.g. sabbatical, visiting, etc.) will also be considered. 7901(A)

COURSES

THE ADVANCED SCHOOL in PROCESS MICROBIOLOGY AND BIOTECHNOLOGY at the UNIVERSITY OF KENT September 16 to 22, 1979

This residential course is intended for graduates in microbiology, biochemistry or engineering working in the multidisciplinary areas embraced by biological processes. Essential features of the course are the "tutorial" system and lectures by eminent visiting speakers.

Course tutors: Dr D. E. F. Harrison, Dr R. C. Righelato, Dr D. Brown, Dr. G. Pace, Dr S. G. Oliver. Visiting Lecturers include: Dr C. Ball, Professor P. H. Clarke, Professor S. J. Pitt, Professor D. W. Tempest, Professor B. Atkinson, Dr D. S. Flynn. Tuition Fee: £150.00 Accommodation (approx.) £90.00.

For further details apply to: Dr S. G. Oliver, University of Kent at Canterbury, Biology Laboratory, Canterbury, Kent, CT2 7NJ.

7947(D)

Agricultural Research Council Institute for Research on Animal Diseases

MOLECULAR BIOLOGIST

A MOLECULAR BIOLOGIST is required to lead a small research team studying the virulence determinants of pathogenic organisms. The binding of the K group of *E. coli* antigen to intestinal receptors has been an especial interest of the team but it is intended to expand work to encompass other related situations.

In addition the person will be expected to advise and assist other project groups.

Qualifications: 1st or Upper 2nd Class Honours Degree in Biochemistry, Molecular Biology or a similar subject and at least four years' relevant postgraduate research experience.

Salary: Senior Scientific Officer scale £5,134 p.a. to £6,898 p.a. or Principal Scientific Officer scale £6,609 p.a. to £8,461 p.a. depending on experience.

Permanent post, with non-contributory pension scheme.

Application forms Secretary, Institute for Research on Animal Diseases, Compton, Nr. Newbury, quoting ref. 274. Closing date for applications October 26, October 1978.

7948(A)

UNIVERSITY OF WOLLONGONG LECTURER IN BIOLOGY (LIMITED TERM) PLANT PHYSIOLOGIST

The Biology Department offers a broadly based first year course followed in second and third years by a coherent series of subjects dealing with functional biology at cellular, physiological and community levels. The appointee will be primarily responsible for a course in plant physiology with emphasis on regulatory mechanisms and environmental interactions, and will also be expected to contribute to other subjects offered by the department. High academic qualifications and significant postdoctoral experience are desired.

Further information may be obtained from Professor A. D. Brown, in the University.

Closing date November 6, 1978

Salary range \$A15,179 to \$A19,940 per annum.

The term of an appointment for a limited term lectureship would be for a period not exceeding four years.

Condition of appointment and application procedure from Association of Commonwealth Universities (Acpa), 36 Gordon Square, London WC1H 0PF. 7921(A)

THE ROYAL VETERINARY COLLEGE University of London

Division of Paraclinical Studies DEPARTMENT OF PATHOLOGY LECTURER IN

VETERINARY PATHOLOGY

Applications are invited from veterinary graduates for the post of Lecturer in Veterinary Pathology. Duties will include participation in teaching the undergraduate and postgraduate courses in pathology at some diagnostic work. The successful applicant will be encouraged to take advantage of the good research opportunities which are available.

Preference will be given to applicants having some relevant experience in postmortem diagnosis, histopathology or similar fields, but consideration will be given to applications from recent graduates or others.

SALARY SCALE (UNDER REVIEW) £4,333 to £8,204 inclusive. London Allowance. Initial salary will be determined according to qualifications and experience. Superannuation under the Universities' scheme.

Removal expenses up to £800 may be reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. Telephone 01-387 2898.

CLOSING DATE FOR APPLICATIONS November 6, 1978. 7964(A)

UNIVERSITY OF HONG KONG DEPARTMENT OF ANATOMY LECTURESHIPS/ASSISTANT LECTURESHIPS IN ANATOMY

Following the establishment of Dental School applications are invited for immediate appointments to the two posts of Lecturer/Assistant Lecturer in Anatomy. Applicants should be either medical, dental or science graduates with teaching experience in the subject. Preference will be given to those with experience in teaching dental students. The appointments also carry responsibility for teaching pre-clinical medical students. The appointees will be expected to engage in research work.

Annual salaries (superannuable) are: — Lecturer HK\$63,540 to HK\$4,260 by HK\$4,320 BA HK\$76,320 by HK\$4,320 Assistant Lecturer HK\$106,140 by HK\$4,320 to HK\$59,22 (£1 equals HK\$9.30 approx.) Start salary will depend on qualifications and experience. A medically-qualified appointee who has completed his pre-registration year will be appointed a Lecturer at the minimum point of the scale.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Acpa), 36 Gordon Square, London WC1H 0PF, or the Assistant Secretary (Recruitment), University of Hong Kong, Hong Kong.

Closing date for applications November 7, 1978. 7899(A)

STERLING-WINTHROP **STERLING**  **WINTHROP** STERLING-WINTHROP

Chemistry Laboratory Manager

We are currently seeking a manager for the Chemistry Department of our Research and Development Division, and are looking for an enthusiastic individual to co-ordinate and develop current activities.

The Chemistry Department plays an important role in the activities of a Group with wide international commitments. Its functions include the synthesis of novel organic compounds with potential pharmaceutical application, the synthesis of compounds for analytical, reference, patent or metabolic purposes, including radio chemicals, a complete analytical service for the analysis and characterisation of compounds produced within the Department, or supplied by Associated Companies throughout the world, and the assembly of data for the registration of new pharmaceuticals.

The successful candidate will probably be aged 27-32, and have some specific experience of the work carried out in this Department together with several years experience of practical Organic Chemistry. An interest in some of the analytical aspects of Organic Chemistry is also essential.

If you would like to find out more about the position, please contact
Colin Davison,
Sterling Winthrop Research & Development,
Edgefield Avenue, Fawdon,
Newcastle upon Tyne, NE3 3TT
Tel: Newcastle 863931 Extn 19

MEDICAL RESEARCH COUNCIL

RADIOBIOLOGY UNIT

RESEARCH APPOINTMENTS

Applications are invited for a

SPECIAL APPOINTMENT

and also appointments in other

SCIENTIFIC GRADES

to study effects of ionising radiations on tissues, especially carcinogenesis from radioactive materials in animals.

Applicants should be well qualified in biological sciences, medicine or veterinary medicine and for the more senior posts have several years postgraduate experience. For at least one appointment experience in histopathology will be an advantage. Qualities of leadership and high academic standing are required for the Special Appointment which is the equivalent of University Professor.

Work at the Unit covers a wide range of scientific interests in relation to protection against ionising radiations and radiotherapy.

Salary in accordance with age and experience on M.R.C. Scales (as at October 1, 1978, with negotiations in progress).

Grade II	Grade I	Senior	Special Appointment
£3,883	£6,317	£7,506	£9,443
£6,080	£7,754	£9,263	£12,247

Enquiries or applications with curriculum vitae and names of two referees to Dr J. Vennart, Director, M.R.C. Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD by November 3, 1978.

7896(A)

**CAPRICORNIA INSTITUTE OF ADVANCED EDUCATION
ROCKHAMPTON QUEENSLAND AUSTRALIA**

Department of Biology

Applications are invited for the position of:

**Senior lecturer/
lecturer in Biology**

Applicants should have at least a good Honours degree preferably in one of the following fields—microbiology, plant physiology, mycology. Suitably qualified applicants in other biological disciplines will be considered.

Industrial and/or teaching experience and a higher degree would be an advantage for appointment as Lecturer and a requirement for appointment as Senior Lecturer.

The successful applicant would be expected to contribute to undergraduate teaching at the degree and associate diploma levels. A significant component of the duties would involve external students and applicants should have a definite interest in this field.

Further details are available from Dr B. Rothwell, Head, Department of Biology (Telex AA48178).

Appointment may be made by means of two or three year contracts or on permanent terms.

Current salary range:

Lecturer \$13,083 to \$18,840 per annum

Senior Lecturer \$20,365 to \$23,737 per annum

Applicants in U.K. or Europe may obtain further information from and make application through the Agent General for Queensland, Queensland House, 392 Strand, London WC2R 0LZ by Friday, 15th November, 1978.

Applications other than from the U.K. or Europe should be addressed to the Registrar, C.I.A.E., M.S. 76, Rockhampton, Qld. 4700, Australia by Friday, 15th November, 1978.

SCIENTIST
NUCLEAR MEDICINE
DEPARTMENT
£3,840 to £5,253**

Applications are invited from suitably qualified graduates, experienced in radio-isotope techniques, to take charge of in-vitro tests in a broad based Regional Nuclear Medicine Department. Applicants must have an interest in developing new techniques and in being involved in research work.

Salary starting point within range according to experience.

Application forms and job description from Personnel Department, Royal Marsden Hospital, Fulham Road, London SW3 (Tel: 01-352 8171, Ext. 446). Closing date October 23, 1978.

7902(A)

THE UNIVERSITY of Manchester, Department of Psychiatry. A Technician (Grade 4) is required for full-time duties in the Department of Psychiatry, Stopford Building (New Medical School). The successful applicant will work with a small research team studying the effects of drugs on the central nervous system. Duties will include assistance with electro-physiological experiments, photography and general laboratory maintenance. Some knowledge of electronics is an advantage.

The applicant should possess H.N.D. or H.N.C. (or equivalent qualifications) in appropriate subjects and have had at least six years' relevant laboratory experience.

Salary range £2,935 to £3,402 per annum.

Applications, together with a curriculum vitae and the names and addresses of two referees, should be sent to Mrs G. Scott, Department of Psychiatry, University Hospital of South Manchester, West Didsbury, Manchester M20 8LR. Closing date for applications: Friday, October 20, 1978.

7931(A)

**TECHNICIAN
GRADE 2B**

required for the Anatomy Department. The work will involve experimental investigation of the nervous system and/or experimental embryology. Applicants should preferably have experience of histological techniques and laboratory procedures in relation to such studies, but those with more general experience will be considered. Applicants should possess an O.N.C. or equivalent qualification. Salary on scale £2,994 per annum rising on scale to £3,345 per annum inclusive. Four weeks annual holiday. Contributory pension scheme. Apply in writing with full details to: The Head Clerk, Ref 204012/N, King's College London, Strand WC2R 2LS.

7922(A)

**MCGILL UNIVERSITY
DEPARTMENT OF
BIOLOGY
POSTDOCTORAL FELLOW**

required to work in a project on the interaction of the killer toxin protein with cell surface receptors in yeast. Experience in protein chemistry and/or yeast genetics an advantage. The appointment is for one year initially and may be renewed for a further two years. Initial salary \$12,100 per annum.

Applications and two letters of recommendation should be sent to Dr H. Bussey, Department of Biology, McGill University, 1205 McGill Avenue, Montreal, Quebec, Canada H3A 1B1.

7908(A)

**INVERESK RESEARCH
INTERNATIONAL**

CYTOGENETICS

The Division of Reproductive Toxicology at Inveresk Research International is undertaking a phase of major expansion, with emphasis on dominant lethal, sperm abnormality and mutagenic assessment. Significant career opportunities exist for the following staff with qualifications and/or experience in relevant areas:

Senior Cytogeneticist: To head up the activity and provide scientific and management input (ref. 2612).

Assistant Cytogeneticists (3): To assist mammalian cells treated *in vivo* and *in vitro* for chromosomal damage (ref. 2613).

Mammalian Mutation Studies Assistants (2): To perform dominant lethal and sperm abnormality studies in rodents (ref. 2614).

IRI is located on the outskirts of Edinburgh within easy reach of the city and the surrounding countryside. The above posts carry a wide range of staff benefit schemes and relocation assistance is provided if required. Application forms, quoting the appropriate reference, are available from Miss J. M. Dunbar, Inveresk Research International, Inveresk Gate, Musselburgh EH21 7UB.

7943(A)

**UNIVERSITY OF
THE WITWATERSRAND,
JOHANNESBURG
DEPARTMENT OF GEOLOGY
LECTURESHP/SENIOR
LECTURESHP IN GEOLOGY**

Applicants should have substantial field and research experience, with emphasis on modern petrogenetic techniques particularly as applied to mineralised terrains. Although it is not a prerequisite for appointment, if the successful applicant has suitable technical and analytical experience in the field of electron probe microanalysis, he will have the opportunity to supervise the operation of the new computerised ARL-SEMQ electron microprobe.

The starting salary will be determined according to qualifications and experience and will be within the range Lecturer, R7,275 to R10,600 per annum, Senior Lecturer, R9,770 to R12,990 per annum. (£1=R170 approx.)

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour.

Further particulars relating to this practice and to the above post are included in an information sheet obtainable from the London Representative, University of Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications (together with the names of three referees) should be lodged by October 23, 1978.

7962(A)

**UNIVERSITY OF
TASMANIA
LECTURESHP/SENIOR
LECTURESHP IN
PATHOLOGY**

Applications are invited for 14 positions within the following scale: Senior Lecturer \$A20,365 2 by \$A675 to 3 by \$A674 \$A23,737; Lecturer \$A15,179 to 1 \$A681 to 6 by \$A680 to \$A19,940. An appointment will be offered from the beginning of 1979 within one of these grades, according to qualifications and experience. An additional loading is paid to medical staff with clinical responsibility. For this appointment, it is expected that the load would be \$A5,000 per annum.

Applicants must hold a medical qualification registrable in Tasmania and should have had experience of the practice of pathology. The successful appointee will be expected to contribute to the Pathology service of the Royal Hobart Hospital, where he will be given an appropriate appointment.

Intending applicants are invited to write to Professor R. A. Rodd, Department of Pathology, in the University, for any further information they may require.

The University reserves the right to offer a short-term contract appointment, or a probationary appointment rather than an appointment with immediate tenure.

Conditions of Appointment & application forms can be obtained from the Association of Commonwealth Universities (Apptd), Gordon Square, London WC1H 0PF.

Applications close on November 1978.

7898(A)

Clinical Trials Scientist

Astra Chemicals Limited is the U.K. subsidiary of Scandinavia's largest pharmaceutical group which specialises in the research, manufacture and marketing of cardiovascular agents, bronchodilators, psychotropics and local anaesthetics.

As part of our plans to extend our clinical trials operation in the U.K. we are now looking for a Clinical Trials Scientist to join our team at Astra's new offices in St Albans.

The objective of this function is to effectively design, monitor and report on clinical trials in support of Astra's pulmonary products. Full product training will be given both locally and in Sweden and the position involves travel mainly within the U.K. and occasionally overseas.

Candidates, aged 28 to 35, should be graduates in biological sciences or in pharmacy (preferably to doctorate level) with previous experience in the pharmaceutical industry.

An attractive salary will be negotiated plus choice of company car and other company benefits.

For further details telephone: (031) 225 2251. Letters of application together with C.V. should be addressed to:

Astra Clinical Research Unit, 65 Queen Street, Edinburgh EH2 4NA. 7934(A)

ASTRA

CLINICAL RESEARCH UNIT

MERSEY REGIONAL CENTRE FOR RADIOTHERAPY AND ONCOLOGY
Clatterbridge Hospital, Wirral, Merseyside, L63 4JY

RESEARCH FELLOW

(MEDICAL STATISTICIAN)

required to undertake the statistical work in a multi-disciplinary evaluation of previous, current and future methods of treatment for the malignant diseases of man. The Clinical Research Unit has been built recently to accommodate the Research Fellow and associate staff.

The person appointed will be responsible for organising the work of this new Unit, which will include analysis of the 260,000 records accumulated in the Regional Cancer Registry serviced by a computer-based system; the design and monitoring of clinical trials concerned with malignant disease, and the production of authoritative reports on the results of the management of malignant disease within the Region. He/she will be encouraged to conduct his/her own research and develop the existing computer-based data processing system.

Candidates should hold a first or higher degree in statistics, or hold a degree in medicine or science and have considerable statistical experience. Some knowledge of medical statistics and epidemiology is desirable. There will be facilities for postgraduate work for a higher degree. If suitably qualified, it is hoped that the successful candidate will develop the liaison with the Biostatistics Unit, Faculty of Medicine, University of Liverpool.

The salary will be in the range of £4,421 to £5,326 and the appointment is for 12 months in the first instance.

Further information can be obtained from: The Clinical Research Unit at the address above. Application forms must be returned within two weeks of the publication of this notice. 7946(A)

EEC PHARMACEUTICAL COMPANY

seeks

DIRECTOR OF RESEARCH

The successful candidate will report directly to the Managing Director and should have particular capabilities in:

- Creativity and initiative substantial experience in pharmaceutical research.
- Strong background in pharmacology.
- The company is medium sized, located in Paris and is already actively engaged in international development and licensing.
- Its research facilities employ approximately 100 people.
- Nationality indifferent, fluent English and French essential.

Please write to: SODECI, 140 Rue de la Croix Nivert, 75015 Paris (France). 7909(A)

Centro Internacional de Agricultura Tropical

CIAT Senior Staff Positions

The Centro Internacional de Agricultura Tropical is a nonprofit organisation devoted to agricultural development in the lowland tropics and is one of ten international centres supported by the Consultative Group for International Agricultural Research. The positions are:

Forages Explorer (Location: Cali, Colombia headquarters). This position is responsible for collecting grass and legume forage ecotypes from acid soil regions of the humid tropics as the main source of germplasm for CIAT's Beef Program; organising and conducting expeditions in cooperation with national institutions; processing, multiplying and maintaining a computerised inventory of forage germplasm. Qualifications: PhD or equivalent in forages or allied disciplines, competence in plant taxonomy, genetics, soils and climate; willingness to do extensive travel in remote areas and interest in collecting for developing improved tropical pastures; and ability to work with other scientists in an interdisciplinary, multi-national team.

Animal Scientist (Location: Carimagua Station, Eastern Plains of Colombia). This position is responsible for research at the herd level to develop and transfer improved beef production technologies based on improved forages in the savannahs of tropical America; for supervising regional studies on actual beef production systems, and for managing a 2500-head experimental herd. Qualifications: International-level animal scientist with PhD or equivalent with competence in both theoretical and practical knowledge of beef production systems in the tropics. Ability and willingness to work as a member of an interdisciplinary, multi-national team aimed at increasing beef production in acid soil regions of tropical America primarily through improved forage production. Must be willing to live in a rural experimental station.

Coordinator, Special Studies (Location: Cali, Colombia headquarters). This position requires an agricultural scientist with agronomic orientation. Responsibilities would include:

1. Supervision of research activities conducted by temporary staff (postdoctorals, visiting scientists) in the areas falling outside or across CIAT's commodity programmes, such as:
 - characterisation of land systems and climatological data for selected regions,
 - evaluation of improved cultivars of food crops and soil-conserving species which may play a role in improving productivity and resource conservation in small scale farming systems,
 - cross-commodity research in specialised disciplines (such as nematology, biochemical physiology, weed science, microbiology and others).

2. Conduct research in one or more of areas described above. Qualifications: PhD or equivalent in crop ecology, plant physiology, climatology, general agronomy or soil science and managerial experience and/or interest.

Coordinator, Data Services (Location: Cali, Colombia headquarters). Responsibilities include management of the Center's computer facilities and statistical services for research programmes, and supervision of six professionals plus clerical assistants. Computational equipment includes an in-house IBM 34 (64K) and telephonic access to an IBM 370/145 (VS1, 1024K). Activities will involve consultation on statistical design, development and interpretation, and development/adaptation of software in support of research activities. Communication at CIAT is in both Spanish and English. Qualifications: PhD or equivalent in biometrics or statistics with experience in agricultural science (or vice-versa) plus experience in operating and managing computers. He should be adept in the commonly used experimental designs, multi-variate analysis and mathematical programming including maximisation and simulation modelling.

Interested applicants should write to Dr K. O. Rachle, Associate Director General for Research; CIAT; Apartado Aereo 67-13; Cali, Colombia. 7967(A)

THE UNIVERSITY OF MANITOBA

invites applications and nominations for the position of

DEAN OF THE FACULTY OF AGRICULTURE

The Faculty of Agriculture at the University of Manitoba has a complement of 99 faculty and 150 support staff. It consists of six units, the Departments of Agricultural Engineering, Agricultural Economics, Animal Science, Food Science, Plant Science and Soil Science and the School of Agriculture responsible for approximately 774 undergraduate degree and diploma students and 206 graduate students in M.Sc. and Ph.D. programmes. The Faculty carries a full range of teaching and research responsibilities and extensive liaison activities with organisations and individuals in the agricultural community.

Candidates should have qualifications appropriate for appointment to a senior academic position and strong leadership ability. Demonstrated knowledge of and preferably experience in Canadian Agriculture will be an important consideration. Relevant administrative experience would be an asset.

The appointment is expected to commence September 1, 1979 and is for a renewable term of normally five to seven years.

Please address enquiries and recommendations to:

Provost R. A. Johnson, Chairman,
Selection Committee for Dean of Agriculture,
Room 202, Administrative Building,
University of Manitoba,
Winnipeg, Manitoba,
Canada R3T 2N2.

Applications will be received until December 18, 1978.

7916(A)

THE ANIMAL VIRUS RESEARCH INSTITUTE

PIRBRIGHT, WOKING, SURREY
Vaccine Research Department

Applications are invited for a senior appointment in the Vaccine Research Department from Biochemists to lead a section on problems relating to the development of methods for the characterisation of antigens such that the essential immunising component of different virus strains can be measured with precision, which could lead to reliable in-vitro estimates of potency. This topic is of fundamental importance and one of the growth points in Foot-and-Mouth Disease virus research. Good facilities are available, including provision for the production and purification of virus at the semi-industrial scale. Candidates should have a good Honours Degree plus several years' experience in this field and proven ability in the biochemical and analytical aspects of animal virus research.

Appointment will be in the P.S.O. grade (£6,609 to £8,461), housing available for married applicant. Further particulars and application forms from Secretary. 7936(A)

RESEARCH ASSOCIATES Ph.D. position INSTITUTE OF BIOLOGICAL SCIENCES, SYNTEX RESEARCH

available immediately to study the role of prostaglandins in kidney function, the relationship of prostaglandin structure to renal function and anti-hypertensive effects and to develop model systems to screen diuretic agents. Strong background in renal physiology essential; some knowledge of pharmacology of prostaglandins and anti-hypertensive drugs desirable. Appointment is for one or two years. Good benefits program. Syntex, a pioneer in the field of steroid chemistry and medicine, is an international pharmaceutical company whose continued growth requires a staff increase. For the highly motivated person this is an ideal opportunity for personal growth and advancement. Send résumé and names of three references to Dr John J. Bruno, Institute of Biological Sciences, Syntex Research, 3401 Hillview Avenue, Palo Alto, Ca 94304. Syntex is an equal opportunity employer m/f/h. 7937(A)

UNIVERSITY OF CAMBRIDGE SHELD PROFESSORSHIP OF PHARMACOLOGY

Applications invited for the above Chair and Headship of Department which is now vacant. Candidature limited to persons whose work is connected with any branch of Pharmacology except Clinical Pharmacology.

Proposed pensionable stipend £10,939 plus £578 for Headship of Department.

Applications (10 copies) marked 'Confidential' should be sent to the Secretary General of the Faculties, from whom further information may be obtained, at the General Board Office, The Old Schools, Cambridge CB2 1TT. Names of two referees may be submitted if desired. Closing date: November 15, 1978. 7945(A)

DERBYSHIRE AREA HEALTH AUTHORITY CENTRAL DERBYSHIRE DISTRICT

DERBY CITY HOSPITAL UTTOXETER ROAD, DERBY SCIENTIFIC OFFICER

Applications are invited for the post of Scientific Officer at Derby City Hospital. The appointee will be expected to partake in a research programme related to the immunological assessment of patients with malignant disease. Techniques involved would include lymphocyte culture, sub-typing and cell freezing.

Candidates should possess a degree or equivalent in a biological science.

Salary scale £2,991 to £4,275 per annum (entry point dependant on qualifications).

For further information about the post those interested should contact Mrs J. Clark, Scientific Officer, Oncology Laboratory (Derby) (0332) 40131, extension 329.

Application forms available from Sector Administrator, extension 428, to be returned by October 22, 1978.

Ref. No. 2156 7383(A)

Freshwater Biological Association RESEARCH ASSISTANT

Vacancy for Assistant Scientific Officer (ASO)—Scientific Officer (SO) to assist in work on the physiological ecology of planktonic algae and environmental factors of lakes, involving experimental and field studies. Two places at 'A' level (or equivalent) specialising in science, or a degree in biology, ecology, or environmental sciences.

Salary ASO £2,188 (age 18), £2,665 (age 21) to £3,303 (max.), SO £2,839 to £4,415 (max.).

Further details and application form from Secretary, Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0LP. Telephone Windermere (096 62) 2468. Closing date: November 10, 1978. 7968(A)

UNIVERSITY OF NEWCASTLE UPON TYNE LECTURER IN AGRICULTURAL AND ENVIRONMENTAL SCIENCE

Applications are invited for appointment to a newly established Lectureship in the Faculty of Agriculture from well qualified persons with research experience of either pollution control or landscape and biological conservation in the countryside. The main teaching duties will involve courses in the above subjects for the interdepartmental Honours Degree in Agricultural and Environmental Science.

Salary will be at an appropriate point on the Lecturers' scale: £3,883 to £7,754 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Registrar, The University, Newcastle upon Tyne, NE1 7RU, with whom applications (3 copies), together with the names and addresses of three referees, should be lodged not later than December 1, 1978. Please quote reference N. 7957(A)

Applications are invited for the following full-time teaching positions. Conditions of Appointment and Method of Application are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications, in accordance with 'Method of Application' will be accepted at any time up to the closing dates stated.

At present all salaries are supplemented by a General Wage Order of NZ\$365 per annum. For Lectureships, commencing salaries will be determined in accordance with qualifications and experience within the scale NZ\$11,529 per annum rising to NZ\$14,123 per annum by six annual increments. In normal circumstances a Lecturer whose services have proved satisfactory to the Council may expect in due course to be given the status of a Senior Lecturer.

GEOGRAPHY

Chair in Human Geography
(Re-advertisement)

Closing date extended to:
October 31, 1978

The position is one of two established Chairs in the Department of Geography. The vacancy arises because of the retirement of Professor K. B. Cumberland on May 31, 1978. The other Chair is held by Professor Paul Williams, who is at present Head of Department. Besides being experienced in University teaching, applicants should be active in research and have a substantial record of research publications. Candidates suitably qualified in any branch of Human Geography will be considered. At present professorial salaries are established within the range NZ\$22,647 to NZ\$28,823 per annum, having regard to the qualifications of the candidates concerned.

GEOGRAPHY

Lectureship

Closing date: November 14, 1978

Applicants should have qualifications within the field of Economic Geography. The Department is especially interested in candidates with expertise in behavioural analysis and/or regional development. Willingness to offer an area studies course would also be an advantage. An opportunity will be given to teach at both the undergraduate and graduate levels.

7920(A)

THE BRITISH COUNCIL

invites applications for the following post:

SENIOR LECTURER IN PLANT GENETICS (Sri Lanka)

University of Sri Lanka, Jaffna Campus
Candidates should hold a Ph.D., preferably in Plant Genetics and have at least 5 years teaching experience. Preferred age range: 30 plus.

Salary: £5,681 to £7,707 p.a. Benefits: Personal allowance, free furnished accommodation and other benefits. Two-year Formula contract.

Return fares are paid. Local contracts are guaranteed by the British Council.

Please, write briefly stating qualifications and length of appropriate experience, quoting reference number 78 PU 102 and title of post, for further details and application form to The British Council, 65 Davies Street, London W1Y 2AA. 7969(A)

Junior Laboratory Scientific Officer required in Department of Microbiology. Some experience of cell culture and virology preferable. Salary according to age and qualifications. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 1RT, quoting Ref. M.C.4. 7890(A)

unilever research

Chemistry Graduates

Applications are invited from recent chemistry graduates for the following two vacancies in our Confectionery Fats Section.

Research Assistant (Ref: CH-480A)

Tasks:

To assist a Scientist in a number of projects in the confectionery fats field involving chemical techniques, blend formulation, computer modelling and general computations. The job also covers the field of product formulation and assessment.

Applicants for this post should preferably be experienced in the use of computers.

Research Assistant (Ref: 481A)

Tasks:

To determine the basic physical chemistry of confectionery fats using techniques such as X-ray Diffraction and Thermal Analysis. The complex interaction of different fats with one another will be studied and evaluated to determine their suitability for use in the confectionery industry.

Colworth Laboratory

Colworth Laboratory is a large, modern, very comprehensively equipped Food R & D Centre servicing Unilever Companies in the UK (Batchelors, Birds-Eye, Walls) and abroad. It is situated in a pleasant country estate ten miles north of Bedford. Salaries and fringe benefits are at a level expected of a large international company and includes assistance with moving expenses where appropriate.

Please write quoting reference number and giving details of career history to:

Miss J. Kenny,
Personnel Officer,
Unilever Research,
Colworth Laboratory,
Colworth House,
SHARNBROOK,
Bedford MK44 1LQ.

7894(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF VETERINARY ANATOMY RESEARCH ASSOCIATE (Re-advertisement)

Applications are invited for the post of Research Associate in the Department of Veterinary Anatomy to work on an A.R.C. funded project on prenatal muscle development in the pig.

The project is for three years starting on December 1, 1978, or shortly thereafter. Applicants should be graduates in Veterinary Medicine, Zoology, Agriculture or a related subject.

The successful applicant will have the opportunity to register for a higher degree.

Applications, before November 3, 1978, together with a curriculum vitae and the names of two referees, should be sent to Dr N. C. Stickland, Department of Veterinary Anatomy, Royal (Dick) School of Veterinary Studies, Edinburgh EH9 1QH, from whom further particulars may be obtained. Please quote Reference 5049. 7941(A)

STRATHCLYDE REGIONAL COUNCIL

DEPARTMENT OF EDUCATION FURTHER EDUCATION

Applications are invited for the undernoted post at Glasgow College of Technology, Cowcaddens Road, Glasgow G4 0BA.

LECTURERS 'A' in BIOCHEMISTRY AND PHYSIOLOGY

Honours Degree in relevant subject(s), preferably with postgraduate qualification, to contribute to the general teaching commitment of the Department including B.Sc. Applied Biology (with Honours) and B.A. Nursing Studies.

Salary scale: Lecturer 'A' £4,029 to £7,116 Bar £7,638. Placing on the salary scale will be given for relevant experience.

Forms of application and further particulars can be obtained from the College to whom completed application forms should be returned not later than October 27, 1978.

EDWARD MILLER, Director of Education.

7961(A)

Research Pharmacologist

Pharmacology Department

Roche Products Limited is part of a major international pharmaceutical company based in Switzerland and is itself one of the leaders in the industry in the United Kingdom.

Applications are invited for a post of Research Pharmacologist in our anti-thrombosis group. The Pharmacology Department is responsible for carrying out research and screening work aimed at the development of new drugs as part of the programme of inter-disciplinary groups.

The work involves routine experimentation and screening and would suit someone who has recently obtained a first degree in Pharmacology or who has a year or so of relevant industrial experience.

Our Pharmacology Department is located in modern laboratories in Welwyn Garden City where the working conditions and facilities are excellent. Conditions of Service include a Christmas Award, 4 weeks' annual holiday, pension fund membership, free BUPA membership and subsidised restaurant. In appropriate cases assistance will be given towards relocation.

If you would like to apply for this post, please write briefly or telephone for an application form (Welwyn Garden 28128) to Mrs Clewley, Research Personnel Department, quoting reference RD33, Roche Products Limited, P.O. Box 8, Welwyn Garden City, Herts. AL7 3AY.

7935(A)

ROCHE

UNIVERSITY OF EDINBURGH

Applications are invited for the post of

RESEARCH FELLOW

in a study of human breast tissue, supported by a three year grant from the Medical Research Council. The project involves electron microscopy, immunohistochemistry and cell kinetics. Applicants should have a Ph.D. or equivalent. Salary Scale is Range 1A, and the appointment will commence as soon as possible. Closing date November 2, 1978.

Applications, including names and addresses of three referees should be sent to Dr T. J. Anderson, Department of Pathology, University of Edinburgh Medical School, Teviot Place, Edinburgh EH8 9AG. Please quote Reference 5057 7915(A)

ROYAL FREE HOSPITAL MEDICAL LABORATORY SCIENTIFIC OFFICER

required to undertake Biochemical investigations for home dialysis patients being treated by our Renal Unit. Applicants should be experienced in Biochemistry and Immunology.

Salary on scale £3,615 per annum to £5,034 per annum inc. Application forms from Personnel Department, Royal Free Hospital, Pond Street, Hampstead NW3. Tel. 794 0500, ext. 4286.

Closing date October 20, 1978 7899(A)

ST. BARTHOLOMEW'S HOSPITAL

London EC1A 7BE

SCIENTIFIC OFFICER

is required to join the D.H.S.S. Toxicology Unit. This Unit carries out investigations into the possible hazards to health by chemicals in food, cosmetics and other consumer products in the environment.

Applicants should hold a degree in one of the biological sciences and preferably have some relevant experience.

Salary according to experience £3,345 to £5,253 inclusive.

Application forms and job description from Personnel Department, telephone 01-600 9000, ext. 3186, quoting Ref. PTA/182.

7950(A)

oxford polytechnic

Lecturer—

Senior Lecturer in Physical Anthropology

(Salary £4,101—(bar)—£7,572)

Applications are invited from those with suitable qualifications to teach Human Ethology, Primatology and Primate Ethology at Honours degree level. Teaching experience and publications in Anthropology and Primate Ethology are preferable.

Lecturer—

Senior Lecturer in Experimental Psychology

(Salary £4,101—(bar)—£7,572)

Candidates for this appointment should be competent to teach Experimental Psychology to Honours degree level, specialising in the areas of Learning and Physiological Psychology. Candidates should have teaching interests in other areas and be ready to teach on introductory courses and to supervise final year projects. Experience in on-line control of experiments and data processing is desirable.

Applications, including a curriculum vitae, and the names and addresses of three referees, should be sent to the Head of Department of Social Studies, Oxford Polytechnic, Oxford. OX3 0BP, from whom further details and application forms may be obtained.

7955(A)

POSTDOCTORAL FELLOW UNIVERSITY OF ALBERTA

Applications are invited from recent Ph.D.'s for the position of Postdoctoral Fellow effective April 1, 1979. Applicants should have a strong background in biochemistry, biophysics or a related area and an interest in conducting research on the organisation and dynamics of lipids in biological membranes and/or on the lipid modulation of the activity of membranous enzymes. Salary is \$11,600 for the first year and \$12,720 for the second year. Send a curriculum vitae and three letters of reference to Dr R. N. McElhaney, Department of Biochemistry, University of Alberta, Edmonton, Alberta, Canada T6G 2H7 7944(A)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF GENETICS AND BIOMETRY RESEARCH ASSISTANT

Applications are invited for this post for work on human gene mapping. It involves linkage studies on enzyme polymorphisms, blood groups and chromosome markers, and a general knowledge of biochemistry and interest in genetical statistics would be desirable.

The post is available for three years, financed by the M.R.C., and the salary will be £3,664 with annual increments. Candidates should have a good Honours Degree and it will be possible to register for a higher degree. Applications, together with the names of two referees, should be sent as soon as possible to Professor E. B. Robson, Department of Genetics and Biometry, The Galton Laboratory, Wolfson House, 4, Stephenson Way, London NW1 2HE. 7894(A)

UNIVERSITY OF LIVERPOOL

Applications are invited for

THREE POSTS OF POSTDOCTORAL SENIOR RESEARCH ASSISTANT

tenable for a period up to three years:

(a) To join a group working on plant sterol biosynthesis. The applicant will study the mechanisms of U sterol side chain methylation reactions using plant tissue culture or cell-free preparations.

Appointments (2) and (3) are to join a group working on the steroidal insect moulting hormone (ecdysteroids) in insects and nematodes.

(b) An ORGANIC CHEMIST/BIOCHEMIST is required to investigate the biosynthesis and metabolism of the ecdysteroids in insects. Experience of steroid or terpene chemistry will be an advantage.

(c) A BIOCHEMIST/PHYSIOLOGIST is required to investigate the structure and metabolism of ecdysteroids in nematodes.

The appointments are tenable for a date to be arranged at an initial salary within the range £3,883-£4,382 per annum plus U Benefits.

Applications, together with names of two referees, should be received as soon as possible.

The Registrar,
The University,
P.O. Box 147,
Liverpool,
L69 3BX

from whom further particulars may be obtained. Quote Ref: RV/957 A, or C/N 7953(A)

SCIENTIFIC SERVICES - TIDAL WATERS

The Tidal Waters Section of the Directorate of Scientific Services of the Welsh Water Authority is involved in the assessment of coastal pollution resulting from the discharge of domestic and industrial waste around the Welsh Coastline and in the evaluation of remedial measures where necessary.

Applications are invited for two posts within this section:

SCIENTIFIC OFFICER

(MARINE OUTFALLS)

Grade 6 (£5133-£5493) or Grade 7 (£5682-£6004) including supplement
(REFERENCE 192)

Within the Tidal Waters section is a survey team responsible for carrying out detailed hydrographic, chemical, and biological surveys to assist in the formulation of these remedial measures. The team requires an Officer to be responsible for the organisation and implementation of the scientific aspects of the Authority's hydrographic surveys, for the evaluation of data so obtained, and for the production of scientific reports clearly outlining the results of the surveys and the options available for sewage disposal.

The successful applicant will have a higher degree or equivalent in physical oceanography (or other relevant discipline) with considerable experience of coastal hydrographic survey techniques and computer orientated evaluation of survey data. Experience of mathematical modelling of coastal circulation and dispersion would be advantageous.

Both posts are based at the Authority's Headquarters in Brecon. The Scientific Officer's post will involve a considerable amount of travelling in Wales and a Regular User Car Allowance will be paid in this post.

Both appointments are temporary for six months in the first instance, but will be subject to consideration for permanency on the forthcoming re-organisation of the Authority.

Further particulars of the post together with application forms, may be obtained from:

WELSH WATER AUTHORITY
AWDURDOD DWR CYMRU

ASSISTANT PERSONNEL OFFICER
WELSH WATER AUTHORITY
CAMBRIAN WAY
BRECON POWYS
LD3 7HP.

Tel: Brecon (0874) 3181.

7929(A)

Closing date for applications: 16th November 1978

IMPERIAL COLLEGE TECHNICIAN (GRADE 3)

Required in a research group working in the field of genetic engineering. The successful applicant would be expected to purify restriction endonucleases and assist with a variety of DNA sequencing problems. Experience of a good theoretical knowledge of techniques of protein purification is desirable. Salary in the range of £3,153 to £3,525 inclusive (under review). Superannuation scheme. Appointment for one year initially but extension likely.

Applications to Departmental Superintendent, Department of Biochemistry, Imperial College, London W7 or telephone 01-889 3111, Ext. 119 for an application form.

7919(A)

EAST BIRMINGHAM HEALTH DISTRICT EAST BIRMINGHAM HOSPITAL BIOCHEMIST, BASIC GRADE (HAEMATOLOGY)

Supervise routine biochemical investigations including abnormal hemoglobins, red cell enzymes, and oxygen dissociation curves. In addition assistance with the current research projects involving erythropoietin and ferritin will be encouraged. Salary range £2,991 to £4,275 depending on qualifications.

For further information apply to Dr C. H. B. Gyde, Department of Haematology, East Birmingham Hospital, Birmingham B9 5ST. Tel. 21-772 4311 Ext. 4282.

Applications, stating details of age, experience and naming two referees. Mrs G. Potts, Assistant Hospital Administrator, East Birmingham Hospital, Bordesley Green East, Birmingham B9 5ST.

7928(A)

UNIVERSITY OF GLASGOW DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT

A Postdoctoral Research Assistant is required for a period of up to 14 months for an S.R.C. supported project on structure-function relationships in transfer RNA. Research experience in Biochemistry or a related subject (and preferably in enzymology or nucleic acid structure) is required. Salary will be within Range 1A of the salary scales for Research and Analogous Staff, £3,883 to £4,382 per annum, according to qualifications, age and experience. Appropriate Superannuation Scheme will apply.

Applications enclosing a curriculum vitae and the names of two referees should be submitted by October 31, 1978, to Dr J. P. Goddard, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No 4251M.

7942(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF BACTERIOLOGY Postdoctoral Fellow/ Research Associate

required to work on a Cancer Research Campaign sponsored project in tumour immunology. Experience in working with tumours or in the field of cellular immunology would be desirable. Salary on National Range 1A.

Schd. c.v. to Dr W. H. McBride, Department of Bacteriology, Edinburgh University Medical School, Teviot Place, Edinburgh EH8 9AG, Scotland. Please quote Reference 5058.

7940(A)

HERIOT-WATT UNIVERSITY DEPARTMENT OF BREWING AND BIOLOGICAL SCIENCES RESEARCH ASSOCIATE

Applications are invited for the post of Research Associate tenable for up to three years for research on yeast cell walls, and yeast cell growth and division under the direction of Professor D. J. Manners and Dr J. H. Duffus.

The salary will be on the Range 1A scale £3,384 to £6,555 per annum (under review).

Informal inquiries may be made to Professor D. J. Manners.

Application forms and further particulars are available from the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX, to whom completed forms should be returned by Saturday, November 11, 1978.

7911(A)

UNIVERSITY OF OXFORD DEPARTMENT OF HUMAN ANATOMY TECHNICIAN GRADE III Salary £2,688 to £3,060 p.a.

A Technician is required to assist with histology and immunocytochemistry, preparation of solutions and animals, and maintenance of a laboratory. Work is in connection with brain research. Knowledge of the cryostat and stereotaxic techniques would be an advantage. The appointment is for a fixed term ending July 31, 1981.

Applications should be made in writing without delay together with the names and addresses of two referees to The Administrator, Department of Human Anatomy, South Parks Road, Oxford, OX1 3QX.

7914(A)

UNIVERSITY COLLEGE OF NORTH WALES BANGOR DEPARTMENT OF TECHNICIAN GRADE 4

£2,955 to £3,402 per annum

Applications are invited for the post of Histology Technician in the Department of Zoology.

The main duties will be the preparation and sectioning of material for examination in the light microscope together with some assistance in the laboratory.

Qualifications required are O.N.C. or an equivalent qualification.

Applications (two copies), giving details of age, education and experience, together with the names and addresses of two referees should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, by not later than October 16, 1978.

7926(A)

UNIVERSITY OF EDINBURGH LECTURESHIP IN PHYSIOLOGY

Applicants must have a good Honours degree in Physiology and at least 3 years research experience. Salary £3,883 to £7,754 per annum. The post is available from January 1, 1979.

Further particulars may be obtained from the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications (6 copies) including a full curriculum vitae and the names and addresses of three referees should be lodged not later than October 31, 1978. Please quote Reference 1074.

7939(A)

Metabolism Chemist

The Plant Protection Division of ICI wishes to recruit someone with post graduate research experience in chemistry, to lead a team studying the metabolism of pesticides.

Applicants must have experience of the use of separative techniques such as glc and hplc, together with a sound mass spectrometry background. Ideally, we need someone who has worked successfully on problems involved with the isolation and identification of small quantities of sample and who has an understanding of the use of labelled isotopes.

The successful candidate will be innovative and will have the ability to motivate and direct a research team. It is also necessary to work constructively in a multi-disciplinary project team.

We offer competitive salaries and there is a Company Profit Sharing Scheme. Assistance with removal expenses and house purchase may also be available. The Research Station is situated on a pleasant farm estate between Bracknell and Maidenhead in Berkshire.

If you are interested in this vacancy please write or telephone for an application form to

Mr D Spence
Personnel Officer
ICI Plant Protection Division

7923(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF OCEANOGRAPHY Applications are invited for the post of LECTURER

in the Department of Oceanography from January 1, 1979, or as soon as possible thereafter. The person appointed will be expected to teach and carry out research in Marine Chemistry.

The initial salary will be within the range £3,883 to £5,367 per annum on a scale rising to £7,754 per annum.

Applications, together with the names of three referees, should be received not later than November 14, 1978, by The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/958/N 7951(A)

BIOCHEMIST—MOLECULAR BIOLOGIST

The Department of Biological Sciences, Carnegie-Mellon University invites applications from molecular biologists whose research interests lie in the area of nucleic acid structure and/or function. Candidates should have postdoctoral experience. The position is at the assistant professor level, although higher appointments will be considered. Duties include teaching at the undergraduate and graduate level as well as maintaining an active research programme. Applicants should forward their curriculum vitae, three or more letters of reference and a brief résumé of research plans to Search Committee (2), Department of Biological Sciences, Carnegie-Mellon University, 4400 Fifth Ave., Pittsburgh, PA 15213. Carnegie-Mellon University is an Equal Opportunity/Affirmative Action Employer 7349(A)

THE UNIVERSITY OF MANCHESTER RESEARCH ASSISTANT IN BIOCHEMICAL MORPHOLOGY

Applications are invited for this post, tenable up to two years, from candidates with a good degree in chemistry or biochemistry, and a strong interest in research, to join a team working on the structure and function of connective tissue. Salary range per annum £3,384 to £4,382. Applications should be sent as soon as possible to Professor J. E. Scott, Department of Medical Biochemistry, Stopford Building, Manchester M13 9PT 7893(A)

TECHNICIAN/RESEARCH OFFICER

required by our Human Tumour Immunology Group at University College Hospital Medical School, London, W.C.1 to assist in the studying of host defence mechanisms against infection in patients being treated with cytotoxic chemotherapy for malignant disease.

H.N.C. or degree with experience in immunology and tissue culture. Salary range £3,615 to £5,256.

For application form telephone or write to Miss S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 on 242 0200, ext 305, quoting reference 303/78 7895(A)

Scientific Publishers, NW London, require P/A for admin/editorial work, part or full time. Please reply to Box No 7906, 3 Dyers Buildings, Holborn EC1N 2NR 7900(A)

THE ZOOLOGICAL SOCIETY OF LONDON

seeks a

CURATOR OF MAMMALS

To manage the Society's Collection of Mammals at Regent's Park, to advise the Society in regard to mammals exhibited both there and at Whipsnade Park and to collaborate in research carried out in the Society's Institute of Zoology.

Applicants should be professional zoologists or veterinary surgeons with a wide knowledge of mammals, and should be competent to carry out research in the field of biology in which they have specialised. They should have had management and administrative experience.

Salary is related to the Senior Lecturer/Reader scale of London University and will be in the scale £6,792 to £9,264 plus London Allowance of £435, with entry point according to qualifications and experience. Pension arrangements are under the Universities Superannuation Scheme and the Universities Supplementary Dependents Pension Scheme. Residential accommodation may be available.

Applications should be made in writing, with details of qualifications and experience and the names of two referees, to:

The Secretary
The Zoological Society of London
Regent's Park
London NW1 4RY

as soon as possible, and not later than November 30, 1978.

7923(A)

ANIMAL DISEASES RESEARCH ASSOCIATION H.S.O./S.O.

A vacancy will shortly occur in the Institute's Physiology Department for a person to be responsible for the running of a Foetal Studies Unit and participation in the experimental programme involving surgical, radioactive isotope procedures and chemical analyses. Previous experience desirable but not essential. Applicants should have an ordinary degree, H.N.C. or equivalent with experience or Hons degree in an appropriate subject. Five years relevant post qualifying experience is required for an appointment at H.S.O. level. Salary Scales—S.O. £2,839 to £4,415, H.S.O. £4,101 to £5,448 with entry according to the qualifications and experience of the successful applicant. Non-contributory superannuation scheme.

Applications giving the names of two referees should be sent to The Secretary, Animal Diseases Research Association, Moredun Institute, 408 Gilmerton Road, Edinburgh EH7 7JH from whom further particulars may also be obtained 7386(A)

UNIVERSITY OF NEWCASTLE UPON TYNE THE DENTAL SCHOOL LECTURER IN ORAL ANATOMY

Applications are invited from dental or science graduates for the whole-time post of Lecturer in Oral Anatomy tenable from January 1, 1979. The successful candidate will be required to take part in the teaching and research programme of the Department of Oral Anatomy which is located in the recently opened new Dental School providing excellent modern teaching and research facilities. Commencing salary will be according to age, qualifications and experience on one of the following scales for dental graduates either Pre-Clinical General Grade £5,129 to £7,754 per annum or Pre-Clinical Higher Grade £7,268 to £8,257 per annum; for science graduates Lecturers' Non-Medical Grade £3,883 to £7,754 per annum. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Registrar, The University, Newcastle upon Tyne, NE1 7RU, with whom applications (three copies), together with the names and addresses of three persons to whom reference may be made, should be lodged not later than November 6, 1978. Please quote reference W 7960(A)

THE UNIVERSITY of Manchester, Technician Grade 3. Applicants should be competent in general histological techniques. The post will also provide experience in electron microscopy, histochemistry and autoradiography. Applicants should have an O.N.C. or equivalent qualification and a minimum of three years' relevant laboratory experience.

Salary scale £2,688 to £3,060 p.a. (scale under review)

Applications in writing, giving details of age, education and qualifications, together with technical experience and the names of two referees, should be made to Professor P. F. Harris, Director of the Anatomical Laboratories, Stopford Building, Oxford Road, Manchester M13 9PT. Closing date October 27, 1978 7932(A)

LIVERPOOL POLYTECHNIC DEPARTMENT OF CHEMISTRY/BIOCHEMISTRY A RESEARCH ASSISTANT/TECHNICIAN

is required for a one-year project funded by the North West Cancer Research Fund entitled: "Studies on the possible carcinogenicity of novel steroids obtained from bile acids by bacterial transformation".

The work involves testing possible carcinogenic compounds using the Ames test, and a test for transformation of mammalian cells in culture.

Applicants should have a degree or technical experience in a Biological Science including experience of Microbiology.

Salary £2,511 plus £312 p.a. For further information apply to Dr R. Bilton or Dr E. A. Haslem, tel 051-207 3581 ext 26.

Application forms and further particulars from the Personnel Office, Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool L3 9RH. Tel 051-227 5581 ext. 43. Please quote reference LP/231 7971(A)

CENTRO DE INVESTIGACIONES Y DE ESTUDIOS AVANZADOS Mexico City, Mexico

Two positions exist in the Department of Genetics and Molecular Biology for Assistant/Associate Professors working with pro- or eukaryotic microorganisms. Laboratory facilities are excellent, teaching responsibilities minimal, knowledge of Spanish is not necessary. Applicants should possess a Ph.D. Send curriculum vitae, names of three referees, synopsis of research and reprints to Dr Jose Rui Herrera, Depto de Genética y Biología Molecular, C.I.E.A. del I.P.N. FELLOWSHIP

French Government Scholarships for further study and postgraduate research in France in Pure and Applied Science, Technology, Medicine, Social Sciences, Economics, Geography and Agriculture are offered for the academic year 1979-1980. Candidates, who must be United Kingdom citizens, should be university graduates or have equivalent qualifications. Closing date December 20, 1978. Details and application forms from Scientific Department, French Embassy, 41 Parkside, Knightsbridge, LONDON SW1X 7JP. Citizens of the Commonwealth and of other countries should apply direct to French Embassies in their respective countries 7904(H).

AWARDS

Awards for RESEARCH INTO TROPICAL RESPIRATORY DISEASES

The Wellcome Trust wishes to encourage research into diseases of the respiratory system, including asthma, occurring in the tropics. A competitive award of up to £100,000 is offered for a period of not more than five years. Preference will be given to proposals which demonstrate an interdisciplinary approach and especially those which include sustained collaboration with research centres in the tropics.

Applications for smaller awards will also be considered and grants may also be made to the runners up. *These awards are additional to the Trustees' normal arrangements for supporting tropical medical research.*

Those wishing to apply should send a two-page summary of their objectives and proposals for research, including a brief estimate of the anticipated costs, for preliminary consideration. The principal scientist should also send a curriculum vitae.

Applications should be addressed to Mr. M. A. F. Barren, The Wellcome Trust, 1 Park Square West, London NW1 4LJ, and reach the Trust by 8th December 1978.

FOR SALE AND WANTED

SCANNING ELECTRON MICROSCOPE for sale. 1969 Cambridge IIA Stereoscan. Fully maintained by manufacturers from new. In daily use. Several attachments. Offers to Dr R. H. Cousins, Gillette Research and Development Laboratory, 454, Basingstoke Road, Reading RG2 0QE. Tel 0734 85222 7910(L).

For Sale. Bank acts and single issues of periodicals in the field of chemistry. List upon request to Box 7385, Nature Advertisement Department, c/o Macmillan Journals Ltd, 3 Dyers Buildings, Holborn EC1N 2NR 7385(L).

MISCELLANEOUS

IF YOU HAVE developed audio-visual program(s) in science on the college level or higher, Science-Thru-Media Co. is interested in possibly manufacturing and marketing your program both nationally and internationally. You will get a royalty on the gross sales. Write or call Terry Hillman, Science-Thru-Media Co., 295 Fifth Avenue, Rm 819, New York, NY 10016, (212) 684-5366 7924(J).

ASSISTANTSHIP

UNIVERSITY OF HULL
DEPARTMENT OF APPLIED PHYSICS

RESEARCH ASSISTANTSHIP
Non Destructive Testing

Applications are invited for a research assistantship tenable for a period of up to two years in the first instance with the possibility of renewal. The research assistant will be involved in the study of magnetic particle inspection testing and ultrasonic testing of a wide variety of industrial components, in collaboration with the Health and Safety Executive, Nuclear Inspectorate.

Salary will be on the scale £3,384 to £4,882 (under review) together with U.S.S. benefits.

Applications, which should include the names of two referees, should be sent by November 1, 1978 to: Dr S. B. Palmer, Department of Applied Physics, University of Hull, Hull HU6 7RX, from whom further particulars may be obtained 7927(P).

The University of British Columbia

Department of Chemistry

GRADUATE TEACHING ASSISTANTSHIPS

Graduate Teaching Assistantships are available for candidates with high academic records who wish to pursue further studies towards the M.Sc. and Ph.D. Degrees in Chemistry. Excellent research facilities are available in all areas of modern Chemical Science, ranging from Bio-Inorganic Chemistry to Chemical Physics. For first year students the minimum stipend, including the summer research assistantship, is anticipated to be \$7,000. Students entering the programme with a Master's degree will receive a higher stipend. In addition, many special merit awards are made to those graduate teaching assistants who show excellence in the performance of their duties. Numerous graduate scholarships are also available for students with outstanding academic records.

Application forms and further particulars may be obtained from the undersigned:

Professor C. A. McDowell
Department of Chemistry
The University of British Columbia
2075 Westbrook Mall
Vancouver, B.C.
Canada V6T 1W5

FELLOWSHIPS

UNIVERSITY COLLEGE CORK POSTDOCTORAL RESEARCH FELLOWSHIP (VIROLOGY/CELL BIOLOGY)

A vacancy exists for a

Virologist/Cell Biologist

to study tumour virus (SV40) host cell interaction through the use of temperature sensitive host cell mutants. The project is funded by the Irish Cancer Society and the appointment will be initially for one year with a possible extension to three years.

Commencing salary will be in the region of £3,600 per annum.
Starting date: by arrangement.

Applications with curriculum vitae and the names and addresses of two referees should be sent **as soon as possible** to Dr J. K. Collins, Virology Unit, Department of Microbiology/Dairy & Food Microbiology, University College, Cork, Ireland.

7954(E)

POSTDOCTORAL FELLOWSHIP

(three years)

available to recent Ph.D. interested in developing **RAPID-RESPONSE CARCINOGENESIS ASSAYS**. Needs good degree in Biology or Biochemistry, ability to work independently. Send application with brief research proposal, curriculum vitae and three references to: Dr Murray Goodall, Cancer Research Unit, University of Otago, Box 913, DUNEDIN, NEW ZEALAND.

7900(E)

NEWNHAM COLLEGE CAMBRIDGE RESEARCH FELLOWSHIPS

The College, acting as part of a Group, invites applications from women educated in Great Britain or the Commonwealth for one or more Research Fellowships which will normally be tenable from October 1, 1979.

Further details, together with application forms (which must be completed and returned not later than November 1, 1978) may be obtained from the Secretary, C.I.A.O., Kellet Lodge, Tennis Court Road, Cambridge CB2 1QJ.

7930(F)

THE QUEEN'S UNIVERSITY of Belfast

RESEARCH FELLOWSHIP

DEPARTMENT OF BIOCHEMISTRY

This post, available until September, 1980, involves research on biochemical aspects of measles and canine distemper viruses. The work is supported by a grant from the Medical Research Council and is concerned with how defective interfering particles may be involved in establishing persistent infections in tissue cultured cells. Candidates should have some years experience in the field of nucleic acids (particularly RNA) and proteins. Experience in handling bacterial or animal viruses would be an advantage.

Salary scale (under review) is £3,384 to £5,130 with superannuation, initial placing depending on age and experience.

Applications giving names and addresses of two referees should be sent to the Personnel Officer, The Queen's University of Belfast BT7 1NN, Northern Ireland. Closing date: October 27, 1978.

7952(E)

UNIVERSITY OF KEELE RESEARCH FELLOWSHIPS IN BIOCHEMISTRY

Two fellowships are available with Professor J. B. Lloyd in the Biochemistry Research Laboratory, Department of Biological Sciences.

1. For work on the nutrition of the early mammalian embryo (M.R.C. supported). Experience with tissue culture techniques and radioisotopes an advantage.

2. For work on the pinocytic uptake and lysosomal digestion of potentially biodegradable synthetic polymers (Cancer Research Campaign). Experience of cell fractionation and enzyme assays an advantage.

Both posts could be filled at either postdoctoral (salary scale 1A, from £3,883 p.a.) or predoctoral (salary scale 1B, from £3,384 p.a.) level.

Further details from Professor J. B. Lloyd, The University, Keele, Staffs., ST5 5BG (tel: 0782 621111, ext. 65), to whom applications, accompanied by a curriculum vitae and the names of two referees, should be sent as soon as possible.

7956(E)

UNIVERSITY OF SOUTHAMPTON HUMAN MORPHOLOGY FELLOWSHIP

Applications are invited from medical or science graduates for a fellowship which will involve a maximum of six hours teaching a week. Previous teaching/research experience, although not essential, would be an advantage. The successful applicant will take part in teaching/demonstrating anatomy and/or histology to medical undergraduates, join a research group studying some immunological aspects of pregnancy, and will be encouraged to register (if appropriate) for a higher degree.

Salary within range £3,883 to £6,555. Minimum at age 26, £4,382 per annum. U.S.S. benefits.

For further details contact Dr S. Peel, Human Morphology, Medical and Biological Sciences Building, Bassett Crescent East, Southampton. Applications giving date of birth, curriculum vitae and the names of three referees should be sent to Mrs. P. Vaughan-Smith, The University, Southampton SO9 5NH by October 27, 1978. Please quote reference 1030/R/Na.

7892(E)

VISITING FELLOWSHIPS FOR RESEARCH IN SOLID EARTH AND ATMOSPHERIC SCIENCE

One year awards offered by C.I.R.E.S., a Research Institute sponsored by N.O.A.A. and the University of Colorado. Stipend is scaled to experience, and the program is open to scientists of all countries. Applications for the 1979-80 academic year awards should be sent to The Director C.I.R.E.S. Visiting Fellows Program, University of Colorado, Boulder Colorado 80309 U.S.A., before February 1, and should include names of three referees, a vitae and publications list, and a brief outline of the proposed research.

An affirmative action equal opportunity, Section 504, Employer.

7387(E)

GIRTON COLLEGE CAMBRIDGE

Applications are invited for a scientific research fellowship open to graduates of any university and tenable for three years from October 1, 1979. The applications should be in the field of Mathematics, Natural Sciences, Geography and allied subjects.

The fellowship is to the value of £2,475 per annum to a candidate with a Ph.D. and £2,255 per annum to a candidate who has not completed a Ph.D. The fellowship is pensionable under U.S.S.

Particulars are available from the Secretary to the Council, Girton College, Cambridge CB3 0JG to whom applications should be sent by November 15, 1978.

7913(E)

STUDENTSHIPS

UNIVERSITY OF WARWICK C.A.S.E. STUDENTSHIP—

KINETICS OF DIAZONIUM SALT REACTIONS BY FAST REACTION METHODS

Applications are invited for a three year S.R.C. (C.A.S.E.) Research Studentship in the Department of Chemistry and Molecular Sciences, starting October 1, 1978, and supervised by Dr T. G. Kemp in collaboration with Dr J. Atherton (I.C.I. Organics). The programme will involve a kinetic study of the decomposition and coupling reactions of ArN_2^+ ions using stopped-flow spectrophotometry combined with a rapid-scanning spectrometer. Applicants should hold or expect to hold at least an Upper Second Class honours degree in chemistry. Further details may be obtained from Dr Kemp, Department of Chemistry and Molecular Sciences. Applications, with the names of two referees, as soon as possible, to the Academic Registrar, University of Warwick, Coventry CV4 7AL. Please quote Ref. No: PG/40/78.

7891(F)

SCHOLARSHIPS/GRANTS

UNIVERSITY OF SYDNEY THE THOMAS LAWRENCE PAWLETT SCHOLARSHIP

Applications are invited from graduates of universities outside Australia who propose to undertake postgraduate study in the Faculty of Agriculture. The scholarship, which is valued at \$A4200 p.a. is tenable for one year, but may be renewed.

Further information and application forms may be obtained from the Registrar, University of Sydney, NSW 2006, Australia, with whom applications close on November 17, 1978.

7973(H)

Help

Our technical services group gets calls all the time from researchers who have found that iodinating proteins can be tricky. We usually have the answers, because at NEN we iodinate proteins ourselves—with our own iodine-125.

Of course, having trouble-free iodine-125 at the outset eliminates some of the trickiness. Ours is the world's most carefully prepared and tested iodine-125.

Each biweekly batch must pass strict tests for radiochemical purity and exact base strength, as well as labeling efficiency in a sensitive lactoperoxidase iodination.

And now the news: We've added a medium concentration, low pH iodine-125. Now you can order any combination of concentration and pH from NEN:

NEZ-033 Standard package
in 0.1-0.5ml
of ~0.1M NaOH solution

NEZ-033H High concentration
>350mCi/ml
in ~0.1M NaOH solution

NEZ-033L Low pH 8-10
High concentration
>350mCi/ml
in aqueous solution

NEZ-033A Low pH 8-10
Medium concentration
100mCi/ml
in aqueous solution

Send for our iodine-125 products brochure.
It tells the whole story.

A new approach in tissue culture

PETRIPERM

a novel culture dish
with gas permeable
membrane as cellular
support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO₂ of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO₂, pCO₂ and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 µm thick membrane.

Heraeus— CO₂-Incubator B 5060 EK/CO₂

We build the
incubator with

Nautiloid growth and lunar dynamics

"Perhaps the most ingenious and effective electrophoretic method for separating proteins is electrofocusing." Lehninger, Biochemistry, 2nd. Ed., Worth, 1975.

Electrofocusing gives you fast, one step separation of multi-protein mixtures.

Superior resolution.

More information. A few of the reasons why

electrofocusing is the fastest-growing technique

in protein separation.

And why you should find out more about electrofocusing and what it can do for your separations.

The one to ask is the company that started it all. The company with the complete system for electrofocusing. LKB. For our special electrofocusing literature, please contact your nearest LKB office. LKB Produkter AB, S-161 25 Bromma, Sweden.

The resolving power of electrofocusing gives you more information because you can separate — in a single run — components which differ in pI by as little as 0.0025 pH units. It is thus suitable for differentiating closely related molecules and is a rigid test of homogeneity for preparation and analysis. This has spurred the rapid growth of electrofocusing as a major technique in biochemistry. To obtain all that electrofocusing promises LKB offers its complete system: Multiphor, for analytical and preparative electrofocusing; LKB Power Supply, with the constant-power output essential for electrofocusing; Ampholine® carrier ampholytes and Ampholine® PAGplates — your standards for electrofocusing. All supported by Application Notes and *Acta Ampholinae* Literature Reference List.

LKB: the only complete source of experience, knowledge, and equipment for electrofocusing.

CARCINOGENESIS: A COMPREHENSIVE SURVEY

Volume 4: Nitrofurans

G. Bryan, editor

This volume surveys the chemistry, metabolism, mutagenicity, activation, and carcinogenicity of nitrofurans, a group of drugs that are carcinogenic for a variety of mammals.

248 pages, \$25.35 (1978)

Volume 3: Polynuclear Aromatic Hydrocarbons:
Second International Symposium on
Analysis, Chemistry, and Biology

P. W. Jones and R. I. Freudenthal, editors

This volume reviews our understanding of the factors that influence polynuclear aromatic hydrocarbon formation, high-sensitivity techniques for the measurement of these widespread environmental contaminants, and their metabolic conversion to biologically active metabolites.

512 pages, \$51.35 (1978)

Volume 2: Mechanisms of Tumor Promotion and
Cocarcinogenesis

Thomas J. Slaga, R. K. Boutwell,
and Andrew Sivak, editors

This volume presents the results supporting the generality of the sequential nature of biological events in carcinogenesis, and is directed to all scientists interested in better understanding the induction of cancer.

646 pages, \$58.50 (1978)

RANDOMIZED TRIALS IN CANCER: A CRITICAL
REVIEW BY SITES [European Organization for Research
on Treatment of Cancer (EORTC) Monograph Series, Vol. 4]

M. Staquet, editor

This is the first volume ever published to review the entire subject of randomized clinical trials in cancer therapy. More than 20 different kinds of human cancer are discussed.

448 pages, \$46.80 (1978)

CHORIOCARCINOMA AND RELATED GESTATIONAL
TROPHOBLASTIC TUMORS IN WOMEN

Roy Hertz

In this monograph the author presents the concept of trophoblastic neoplasia as a biologically continuous spectrum consisting of the clinical entities of hydatidiform mole, invasive mole, and choriocarcinoma. This comprehensive presentation covers salient features of trophoblastic disease with respect to epidemiology, pathogenesis, and treatment.

150 pages, \$19.50 (1978)

Mail your order to:

PROGRESS IN CANCER RESEARCH AND THERAPY

Volume 9: Endocrine Control in Neoplasia

R. K. Sharma and W. E. Criss, editors

The 38 chapters in this volume, by leading authorities in the field, focus on the mode of action of hormones in carcinogenesis and tumor development, and include the most recent studies concerning hormonal responsiveness in a dozen forms of cancer.

381 pages, \$41.60 (1978)

Volume 8: Polyamines as Biochemical Markers of Normal
and Malignant Growth

D. H. Russell and B. G. M. Durie

This monograph provides clinicians with a treatise that details the role of polyamines as biochemical markers of success and failure in cancer chemotherapy.

198 pages, \$22.75 (1978)

Volume 5: Cancer Invasion and Metastasis:
Biologic Mechanisms and Therapy

S. B. Day, W. P. L. Myers, P. Stansly,
S. Garattini, and M. G. Lewis, editors

In this important new volume, leading researchers in the field of metastasis control present an up-to-date account of the current status of this crucial research area.

540 pages, \$45.50 (1977)

Volume 3: Genetics of Human Cancer

J. J. Mulvihill, R. W. Miller, and J. F. Fraumeni, Jr., editors

This volume examines cancer in special populations, and includes a discussion of population genetics. Approximately 200 single gene traits that involve neoplasia are described and the applications of the concepts of population and clinical genetics to a more basic understanding of carcinogenesis are discussed.

541 pages, \$29.25 (1977)

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

This is Mettler DeltaRange:

A ten times more accurate fine range, available anywhere within the overall weighing range, when maximum precision and large capacity are needed at the same time.

Available only with the new electronic PC top-loading balances from Mettler.

METTLER
Precision you can depend on

6302.72

PC440 and PC4400. Precision – Capacity – Versatility.

Always one step ahead. Mettler DeltaRange breaks down the barriers that used to restrict the capacity/accuracy ratio of conventional balances. Besides, Mettler PC balances can do a lot more than weigh unknowns. They can also calculate percentages, count small parts, determine running net totals, etc.

19 October 1978

Popular science

THE above three graphs show changing patterns in popularity of various subjects amongst applicants to British universities over a period of fifteen years. The figures have been compiled from annual reports of the Universities Central Council on Admissions (UCCA), culminating in the Statistical Supplement to the Fifteenth Report, published recently. These reports have over the years consistently listed the number of candidates applying through the UCCA scheme for entry to any British university (excluding the Open University, University College, Buckingham and to a lesser extent three Scottish universities) by their first choice for study.

There were some changes in subject headings between 1963 and 1967 which mean that comparisons must be made a little cautiously (although there seems no evidence that the subject headings are seriously incompatible). Since 1967 the headings have remained the same, however, so there is no reason to doubt that year-by-year comparisons can be made. The figures are percentages of all applicants naming particular subjects as first choice. The total number of applicants in 1963 was 51,596 and in 1978 is about 180,000. Between 1963 and 1967 the number rose to 90,952; it has risen more slowly since then. Only one subject, chemistry, actually has less applicants in 1978 than in 1963.

As with all statistics, some cautions have to be given. These are not figures for admissions to university, so they do not reflect actual changes in size of intake. Very many students naming a preferred subject are happy, or at least willing, to be accepted for another subject. Furthermore, the figures say nothing about the quality of candidates. Many of those who apply simply do not have the necessary qualifications, and cannot be regarded in the final analysis as serious candidates for a university. Also amongst those who are serious candidates, there is probably substantial variation from subject to subject in the quality of applicants. Finally, the figures for 1978 are only estimates, though accurate ones.

What can be claimed is that the graphs represent fairly well the ambitions of 17-year-olds over a period in which a much greater number of students have been able to contemplate university education, and in which society's attitudes to various professions have changed substantially. Perhaps there are two points worth underlining. The first is that the vast expansion in educational opportunities in the 1960s did not stimulate in any way a proportional increase in the number of those doing the 'central' sciences. Secondly, contrary to popular belief, enthusiasm for engineering courses has actually grown fairly steadily for many years. □

Power-failure knocks out Seasat

A POWER-FAILURE thought to have been caused by a short circuit has cut off all communication with the experimental ocean-monitoring satellite Seasat-A, launched less than four months ago by the National Aeronautics and Space Administration.

Attempts by NASA's Jet Propulsion Laboratory in California to re-establish contact with the satellite have so far been unsuccessful. And it is feared that the satellite, which cost \$75 million to put into orbit, and was expected to continue to provide data for up to three years, may now have to be written off.

Seasat is primarily a "proof of concept" satellite designed to test the performance of a set of microwave sensors, including in particular a synthetic aperture radar which is able to gather data on the behaviour of the ocean's surface even through dense cloud.

In the four months since the satellite was launched considerable quantities of data have been successfully gathered and stored for future processing. NASA officials claim that the results processed so far indicate that the behaviour of the equipment has been "amazingly good".

However the apparently short life of the satellite has been a major disappointment to scientists who had expected to make use of a full range of data in a series of oceanographic and meteorological studies not only in the US, but also in Canada and Europe.

Canada's Department of Energy and Mines, for example, which is collecting Seasat data at a receiving station in Newfoundland, was in the process of a major survey of arctic

ice flows using simultaneous data from aircraft and the satellite. The survey will now have to be completed using aircraft data alone; and although the impact on the project is not likely to be substantial, one scientist described the loss of further Seasat data as a "considerable blow".

The trouble occurred last Monday when Seasat was in its 1503rd orbit. According to NASA officials the satellite seemed to be behaving normally when it passed over the receiving station at Orrora in Australia; however when it came within sight of the next station at Santiago in Chile, it was discovered that the batteries were discharging at full rate.

As the voltage dropped rapidly, various sensors began to shut down, and within a few minutes the satellite ceased to respond to commands sent up from ground control stations. A little later communication from the satellite to Earth also cut out.

Laser beams bounced off special reflectors on the bottom of the satellite as it passed over Bermuda showed that it was still on course. However continued attempts to get the satellite to switch off all non-essential equipment, in the hope that solar cells might recharge the batteries, have apparently so far met with little success.

Various bursts of data thought to be from Seasat were reported last week by several receiving stations, including one at Oakhanger near London, but it turned out that these had been transmitted from the earth-monitoring satellite Landsat-3.

The cause of the power failure is not yet known (although NASA officials were denying rumours that it might

have been knocked out by a Soviet anti-satellite weapon). However late last week it was discovered that a recorder left on for practice purposes at Oakhanger had been receiving signals at the time of the failure, and its data is now being studied to see if any clues to the short-circuit could be found.

Because of tight budget restrictions, Seasat-A is a one-off satellite with no back-up available. Although officially planned to remain in orbit for only one year, it had been supplied with sufficient resources to last for three. The soonest that a follow-up satellite could be launched, even with Congressional approval, would be 1983. □

Carter outlines future strategy for space science

PRESIDENT Carter has officially confirmed that there are unlikely to be any further US "space spectacles" such as the Apollo project during the next decade, and that while the administration remains committed to a strong space science programme, this must remain sufficiently flexible to absorb financial constraints "when conditions warrant".

However, included among future space science goals will, in addition to planetary studies currently underway, be more detailed exploration of Saturn and its moons and rings, and the reconnaissance of comets and asteroids.

These decisions were announced last week following a policy review of civilian space policy carried out by an

interagency committee set up four months ago under the chairmanship of Dr Frank Press, director of the Office of Science and Technology Policy.

The president's statement contains few surprises, and reflects the more cautious—some would say conservative—path that the National Aeronautics and Space Administration has been pursuing in the past few years. Its general message is that if there is to be a major expansion in space activities, the main stimulus is to come from private industry rather than the federal government.

As for space science, the statement lays down broad principles rather than specific objectives. Thus President Carter says that US space policy will

reflect a balanced strategy of application, science and technology development which will "assure American scientific and technological leadership in space for the security and welfare of the nation".

Such a policy will, he says, "emphasise space science and exploration in a manner that retains the challenge and excitement and permits the nation to retain the vitality of its space technology base, yet provides short-term flexibility to impose fiscal constraints when conditions warrant."

The president's statement says that it is neither feasible nor necessary at this time to commit the United States to a "high-challenge space engineering initiative" comparable to Apollo, and

that the now declining costs of the Space Shuttle development programme gives the administration "the flexibility to give greater attention to new space applications and exploration, continue programs at present levels, or contract them." Funds to cover these will be "adequate."

Turning to space science, the president says that in addition to continuing a vigorous programme of planetary explorations to understand the origin and evolution of the solar system, the US will utilise the space telescope and free-flying satellites to usher in "a new era of astronomy" which will include the exploration of interstellar molecules, quasars, pulsars and black holes.

The most controversial part of the statement comes in the section covering space applications, and in particular the future direction of earth monitoring systems such as LANDSAT. The

administration has been under Congressional pressure for some time to come up with a clear set of policy goals and long-term objectives.

Last month, for example, Senator Adlai Stevenson, chairman of the Senate subcommittee on science and space, introduced a bill which would require the president to present Congress annually with a five year forward-plan clearly laying out the administration's space objectives and how it proposed to meet them.

However, so far the administration has backed away from any firm commitment of this nature. And last week's statement merely says that, in the case of remote sensing systems, NASA will chair an interagency task force "to examine options" for an integrated system, and that a comprehensive plan covering all aspects of remote sensing "will be explored." □

World climate conference thrown open to social scientists

WHEN the World Climate Conference meets in Geneva in February next, it will involve some 400 participants instead of the 100 or so originally envisaged by its organisers at the World Meteorological Organisation (WMO). So now the social as well as the physical sciences can be represented—a move in line with the new trend of thinking on the role of science in the United Nations system. This broader participation also underlines the main objective of the conference "to examine the impact of climate on various aspects of human welfare, and especially of climatic fluctuations on all time scales".

WMO's Secretary General Dr D. A. Davies points out that the effects of cold spells and droughts have in recent years presented grave problems affecting energy supplies and agricultural output even in the most highly developed countries. At the other end of the economic ladder, the effects of the disaster caused originally by the drought in the Sahel in the early 1970s

are still causing grave concern. So this effort to bring about a "meeting of the minds" between the meteorologists and the behavioural scientists, biologists, economists and others in relevant disciplines is certainly not being made a moment too soon.

Nevertheless no great scientific surprises are expected to emerge from next February's meeting. As WMO sees it, hard evidence does little to support many of the disaster hypotheses of the doom-watchers. It is admitted, however, that there is one major exception: the problem of increasing CO₂ in the atmosphere. This is something in which WMO is seriously engaged, and is considered important enough for a major global effort to be made in the immediate future: the proposal is to use a wide network of regional observing stations, together with a smaller number of permanent baseline stations sited so as to cover the whole of the Earth's surface.

Peter Collins

"Erosion of spirit" in British science

THE morale of academic research scientists in British universities is at a low ebb, according to the Trustees of the Nuffield Foundation, a British charitable organisation which supports university research.

Writing in the annual report of the foundation, the trustees claim to observe "what appears to be an erosion of the spirit in scientific and medical research at British universities and polytechnics". The trustees base this

assertion on the fact that the Nuffield Foundation "has received many fewer applications of high quality for research grants in science and medicine than would have been expected if university departments were bursting with ideas and needing only financial resources to carry them through". The morale of the younger members of the community is particularly affected, says the report.

The trustees select lack of growth in

ICSU investigates refused visas

ICSU the International Council of Scientific Unions—is to investigate the complaint of a group of Israeli geneticists who failed to receive visas for the fourteenth International Congress of Genetics, held in Moscow last August.

Originally, 33 members of the Israeli Society of Genetics registered for the congress and received a registration number, indicating that their application was accepted. However, a month before the congress, visas had not yet arrived.

On 10 August, the Israeli Society of Genetics cabled Professor Ralph Riley, secretary of the International Genetics Federation, suggesting that the federation withdraw its sponsorship of the congress. This, it appeared, was impossible, both because the federation was financially committed, and also because it was feared such an action would "throw Russian genetics into turmoil again".

Eventually 18 visas arrived—restricted to the exact dates and place of the congress and with no provision for accompanying spouses nor for participation in the traditional post-congress excursions. At this the Israeli Society of Genetics decided to recommend its members not to attend—a recommendation which was duly followed. Instead, two delegates attended to put the Israeli case formally.

After various unofficial discussions, the case was raised at the representative council of the federation, and a resolution was passed, mild in tone, but demanding that "steps should be taken to ensure that all applicants to further congresses receive their visas in due time".

Last month, when the ICSU general assembly met in Athens, the resolution was brought to the attention of the Committee for the Free Circulation of Scientists. The Committee, which includes among its membership a representative of the Soviet Academy of Sciences, has undertaken to look into the matter.

Vera Rich

the universities as the main culprit: "younger people . . . can no longer set their sights on what until quite recently was the chief objective of young creative scientists—to be so successful in their chosen field as to make a mark not only in the scientific literature but on the pattern of research in their institutions."

The foundation offers to help—if anyone can come up with a practical proposal. □

Brazil's scientists fan doubts over energy priorities

David Dickson describes how problems with Brazil's nuclear programme have highlighted tensions between the government and the scientific community

ONE of the major issues that Brazil's new president will have to face when he takes power after next month's elections is whether the country should make a major shift in its energy strategy.

Officially the central component of this strategy remains a firm commitment to the rapid development of nuclear power, a programme under which the country is scheduled to possess nine power stations by 1990, and to be meeting 40% of its energy needs with nuclear power by the year 2000.

Criticism of the programme by Brazil's scientific community on technical, economic and political grounds appears so far to have been virtually ignored by the country's military leaders. And external criticism, such as the US's attempts to dissuade Germany from selling Brazil a re-processing plant on the basis that it would increase the danger of the proliferation of nuclear weapons, has hardened the nation's resolve to pursue its nuclear goal.

However, three factors are now putting strong pressure on Brazil's leadership to revise its current stance. The first involves problems and delays that have already occurred in the nuclear programme itself; in particular the extra construction work that has been made necessary by the discovery of geologic instabilities at present reactor sites.

The second is the rapidly increasing costs of the programme. Partly a result of the costs of the extra design and construction work, and partly due to the declining value of the cruzeiro against the Deutschmark, nuclear

power is becoming a much less attractive proposition on economic grounds when compared to more conventional sources such as hydropower.

The third factor is the success that has already been achieved in Brazil's crash programme to substitute the use of ethyl alcohol for petroleum. Unlike nuclear power, the alcohol programme is well on the way to meeting its initial target of 4 billion litres a year by 1980; a further source of pride is that it has been based almost entirely on indigenous research and development. In many of Brazil's major cities cars now use a mixture of 20% alcohol, and by 1981 one-sixth of all new cars are planned to run on alcohol alone.

At the very least, some of Brazil's scientists now argue, the \$1.6 billion alcohol programme has removed the worst pressures of the energy crisis which had had such a dampening effect on Brazil's previously explosive economic growth, thus giving the country more time to consider the details of its nuclear future.

"Most scientists and industrialists would probably prefer a more modest programme in which they could play a dominant role and acquire the necessary technology" according to Professor Jose Goldemberg, director of Sao Paulo University's Institute of Physics, who has suggested that a prototype reactor working on the thorium cycle might be the most appropriate way forward.

Others go further to suggest that, given the vast potential of the nation's renewable energy sources—in particular in the fields of hydropower, solar

energy and the use of biomass—the most desirable option from both a technical and a social point of view would be for Brazil to drop its nuclear programme altogether.

The oil crisis of 1973 hit the country particularly hard. Unlike neighbouring Venezuela, it has little petroleum reserves, and intensive prospecting has been relatively unfruitful; 83% of its petroleum is now imported, at an annual cost of \$4 billion.

Even before the crisis, Brazil had committed itself to nuclear energy, signing an agreement with the US firm Westinghouse to build a 625 megawatt reactor on the coast at Angra dos Reis, 115 miles south-west of Rio de Janeiro, in 1969.

Construction work started in 1972, but has been plagued with problems. These range from an embarrassing fire last year, which caused \$10 million of damage to equipment and raised awkward questions about construction procedures and security, to the discovery that the site was on top of a rock platform that was slowly being pushed into the sea—and that a retaining wall was therefore needed to shield it from the pressure of earth moving down a nearby mountainside.

Other problems have been experienced with the subsequent contract for the construction of eight 1,300 megawatt reactors which Brazil signed with

Cars in Sao Paulo now run on a mixture of 20% alcohol

It's all right, sir. It's only suffering from a hangover!

Plagued with problems: Brazil's first nuclear power station under construction

West Germany in 1975. The package included not only equipment, materials and technical assistance, but also covered the construction of an enrichment plant and a reprocessing plant, providing, it had been hoped, the basis for Brazil's nuclear power programme to become self-sufficient.

It has been the inclusion of the enrichment and the reprocessing plants that have so far attracted the most outside attention. In addition to the Carter administration's attempts to block the sale of the latter, the Dutch government almost refused to allow the supply of enriched fuel from the European Urenco consortium because of concern over safety arrangements.

Such arguments, however, have few supporters inside Brazil. The military rulers have accused the US of interfering in another country's sovereignty, the same reason given for refusing to sign the Non-Proliferation Treaty; and even the government's political opponents, while expressing concern on the safety issue, have rallied behind it in rejecting outside pressure as "technological imperialism."

However, criticism of other aspects of the programme has been far from absent. Three issues in particular have attracted the attention of Brazil's scientific community, among whom the physicists have been especially vocal.

The first criticism is that, in buying the technology as a total package with no alteration permitted to the German design—even though the construction of parts will slowly be taken over by Brazilian contractors—no real transfer of technology will have taken place, and the Brazilians will have learned little about reactor design.

"The technological aspect of nuclear energy is vitally important, and we would like to learn how to develop our own technology so that we can develop a truly independent programme," says Professor Jose Moreira of the Institute of Physics, who claims that the short period spent in Germany by most of those sent to learn about nuclear tech-

nology means that little transfer of knowledge is likely to take place.

The second criticism relates to the proposed method for enriching uranium. The Germans have proposed using the as-yet unproven Becker jet-nozzle process. Research results, however, have so far been disappointing, and have led to the crack that Brazil is paying with money it does not have for technology that Germany does not possess.

Both of these relate to the third, broader criticism; that in developing its nuclear programme, the Brazilian government has taken little account of what its own scientists could or might be able to offer, and has thus neglected the opportunity to build a nuclear power industry truly independent of foreign interests.

Professor Moreira points out, for example, that at present Brazil has about 800 PhDs in nuclear physics, more than enough to establish a viable reactor research community, but that universities and technical institutes have been virtually ignored in the government's nuclear plans.

Similarly a group of physicists recently produced a report on "Panorama and Perspectives on physics in Brazil", which criticised the lack of interaction between the government nuclear company Nuclebras and the physics community, claiming that this appeared to be a deliberate policy, and pointing out that the considerable scientific resources of Nuclebras were not available to outside scientists.

The situation has historical roots. Back in the late 1960s when the nuclear plans were being drawn up, universities were a focus of opposition to the military government's authoritarian policies, and many staff members—including scientists such as Dr Leite Lopes, then scientific director of the Brazilian Centre for Research in Physics, and now professor of particle physics theory at the University of Strasbourg—lost their jobs.

A reluctance at the time to provide university research funds for a subject

as sensitive as nuclear energy is therefore little surprising. And the government even disbanded the main research group in the country, the Institute of Radioactive Research at the Federal University of Minas Gerais.

One consequence of the lack of involvement of universities, however, has been the reported difficulty of attracting scientists of sufficient calibre into the nuclear programme. For example it is claimed—although difficult to confirm, since the whole programme is shrouded in secrecy—that this is one reason why government laboratories have had such difficulty in developing the enrichment technique, even on an experimental basis.

"More than the petrol crisis, what is obstructing Brazilian development is the lack of human resources," Professor Jose Ellis Ripe, a physicist from the University of Campinas, held a conference last month on physics education. This, he said, was the result both of a low investment in education, including in particular education in the basic sciences, and a preference for investing government money in areas that promised a quick return.

One area of slightly less sophisticated technology in which Brazilian scientists and technologists have been able to get a firm grip has been in electric power transmission. Brazil and Paraguay are currently building what will be the largest hydroelectric dam in the world on the Parana river, eventually producing 12.6 gigawatts; Brazil has agreed to buy any power that Paraguay does not need, but since the two countries' electricity supplies are at 50 and 60 cycles a second respectively, Brazil is transmitting the power to its urban centres as direct current before reconverting it to alternating current.

Factors such as the need for smaller cables means that high voltage direct current transmission becomes more economical over a distance of about 700 kilometers. And engineers are now putting together ambitious plans to use such techniques to transmit hydro-power 2000 kilometres from the Amazon basin to the country's industrialised areas in the south, whose energy needs had previously stimulated the nuclear power programme.

But the area which has given the greatest boost to Brazil's self-confidence in its research capabilities has been the alcohol programme. From modest beginnings only a few years ago, the research programme has mushroomed under the personal support of President Geisel to a position in which several hundred separate projects are planned or operating, with a total budget of \$65 million over the next two years.

Even US scientists admit that this is an area of energy research and deve-

lopment in which Brazil has established an advantage over all other countries, and there has been much international interest—for example from scientists in West Germany and Scandinavia—in the programme and its results.

Reception of "gasohol" by consumers has been mixed; there are complaints of timing problems—the streets of São Paulo are filled with frequent back-fires—of difficulties in starting on cold mornings (overcome by the addition of a small pre-heater) and of an increase in fuel consumption.

Research scientists at the Aeronautical Technical Center near São Paulo, where much of the enthusiasm initially came from and where there are currently 34 separate programmes looking at engine design, insist that such problems are relatively minor, and that the technical feasibility of using alcohol in petrol on a large scale has now been clearly established.

In other places, much research is being carried out into the supply side. Initially the prime candidate for transformation into alcohol had been manioc, a root vegetable widely used by Brazil's native Indian which grows in poor soil with relatively little water—two characteristics of Brazil's Northeast region in which social conditions are worst, and needs are greatest.

However at present the main emphasis is being placed on methods of producing alcohol from sugar cane. Although unlike manioc, which can be harvested at any time, cane can only be collected for six months of the year, it is considerably easier to extract the sugar required for fermentation, and the outside sheath, known as bagaco, can also be burnt to provide the energy for the fermentation process.

Government officials, their appetite whetted by the apparent success of the alcohol programme, are now busy following up the potential uses of other biological materials. One prime candidate under consideration is the nut of babacu palm tree, at present used almost exclusively for its seeds, which are extracted from the nut's core and crushed to produce their oil.

Plans are now being studied to use each of the various parts of the nut for different purposes; the seeds to make palm nut oil, the core to make charcoal and gas, the shell to make alcohol, and the skin for primary combustion.

In addition to building the self-confidence of the research community, the whole field of alternative energy sources is proving to be a fruitful outlet for university scientists who had been previously frustrated in attempts to link their work to socially useful objectives.

The involvement which started with criticism of the government's nuclear

policy is now being channelled by some into more pragmatic goals. This process has been encouraged by the availability of funds from the federal government, which has recently set up an office in the Ministry of Mines and Energy, under the title of Project Ipiranga, to centralise research efforts on non-conventional sources of energy.

A group of physicists at the Federal University of Rio de Janeiro, for example, under the direction of Dr Luiz Pinguelli, is now looking at the energy options facing state power companies.

Similarly Professor Goldemberg and Professor Moreira in São Paulo are looking at ways of increasing the efficiency of the conversion processes applied to biological materials. In particular, they are investigating both theoretically and experimentally ways of using fluidised bed combustion to increase the efficiency of burning the sugar-cane bagaco which they claim could be used as an important source of electricity for other domestic and industrial purposes.

But the more general sense of frustration and exclusion remains. Many scientists, for example, are now calling on the government to permit the return of those of their colleagues who had previously been expelled, claiming that the country needs to do what it can do build a base that can shore up its ailing economy.

There have also been requests for greater participation in decision making on technological issues, as well as in the assessment of the general direction of bodies such as the National Research Council, Nuclebras, and even the Ministry of Education.

So far, despite the slight loosening of earlier restrictions, there has been little response to such requests. And in energy policy at least, there remains the feeling that political interests continue to play a dominant role.

One reason for the switch from

manioc to sugar cane in the alcohol programme, for example, was that despite the social advantages of the former in bringing work and income to the country's most depressed areas, the dramatic decline in world sugar prices in 1973/74 meant that the large sugar-cane producers needed new outlets for their produce, and pushed for their inclusion in the programme.

Nor are established interests far below the surface in the nuclear energy field. Thus there has recently been a scandal involving the close connections between the Minister of Trade and Industry and the owner of a previously obscure engineering company which was awarded, without any competitive bidding, the contract for the construction work for the first two German reactors, Angra 2 and 3.

Furthermore Brazil can expect heavy pressure from Germany if its attempts to back out—as Iran is now reported to be contemplating—from its previous commitment, even though, according to Mr Arnaldo Barbalho, president of the state-owned electricity company Eletrobras, "the agreement speaks only of the purchase of up to eight nuclear power stations."

Finally with Argentina, Brazil's main economic competitor in the South American continent, already successfully operating one reactor and building more, any suggestion of cutting back on nuclear plans is unlikely to be warmly received in military circles.

Last month the Brazilian congress, largely under pressure from the opposition party MDB, agreed to set up in the Senate a parliamentary commission of inquiry into the country's nuclear policy. Some scientists feel this could be an opportunity to explore the viability of a major shift towards alternative, mainly renewable energy sources. The technical potential has been demonstrated; the political will is now required. □

Argentina plans nuclear reprocessing plant

ARGENTINA is soon to start construction work on an experimental plutonium reprocessing plant, and could be operating a complete nuclear fuel cycle with domestic technology by 1990, according to Admiral Raul Castro Madero, President of the Atomic Energy Commission.

The reprocessing plant will be situated in the grounds of the Ezeiza Atomic Centre outside Buenos Aires. A laboratory scale reprocessing plant was built at Ezeiza in the early 1960s, and is said to have produced a few milligrams of plutonium before it was dismantled.

According to a report in the

Washington Post, Argentina is also planning to start production of a heavy water plant. The country already operates a natural uranium reactor—the only nuclear reactor presently operating in South America—and this would give it the capacity to produce nuclear fuel using domestic technology.

Since Argentina has not signed the nuclear non-proliferation treaty, it would be able to produce weapons-grade plutonium free of international safeguards. However, Admiral Madero said in an interview that the country had "no need for nuclear weapons". □

Israel's place in the sun

Israel's abundance of sun and scientists has led to great interest in the application of solar energy, writes **Vera Rich**

ISRAEL, it may be claimed, has had an interest in solar power dating back some 3,500 years—when Joshua ordered the Sun to stand still! But today there is a boom in the more scientific uses of solar energy in the country.

The modern era of Israeli solar power dates back to 1911, when a mining engineer from Siberia, Moshe Novomeiskii, first visited the Dead Sea. Novomeiskii realised that the combination of arid atmosphere and virtually unlimited sunlight (the annual rainfall is about 5 cm) would make the extraction of mineral salts by evaporation commercial. By 1930, the first plant, at the northern end of the Dead Sea, was in operation, and in 1934, a second plant was opened at S'dom, at the southern end of the sea, where the terrain is suitable for the construction of very large evaporation pans.

Following partition in 1948, the northern plant came into Jordanian hands, and was later destroyed; but the S'dom plant has become the basis of Israel's potash and chemical industry. The evaporation pan system now covers 130 km² and has a capacity sufficient to produce 1,250,000 to 1,400,000 tons of phosphate a year, much of which is exported, as well as bromine compounds and magnesium and sodium chlorides. The solar energy consumed in the evaporation process is estimated to be equivalent to more than Israel's annual output of electricity.

For some years, the Dead Sea works remained Israel's only effort in the use of solar energy. Then, about 20 years ago, the first solar-powered hot-water systems began to go into operation. At

the present time, even the prefabricated homes of the small Negev settlements have roof-top water heaters (two solar panels and a drum), and it is estimated that some 35% of the population enjoys solar hot-water—a total which would doubtless be higher had not certain local authorities banned roof-top storage tanks for aesthetic reasons.

Following the oil crisis of the early 1970s, and in view of the fact that Israel has so far located only minor deposits of oil and gas within the "green line" (the pre-1967 frontier), there is now a boom in all types of solar energy exploitation. At virtually every institute of higher education in Israel, a number of solar energy projects are going forward, in any available corner. Even the spacious Weizmann Institute seems to find it impossible to house all its solar team in an appropriate building, and one can find solar energy work going on, for example, in the basement of the animal breeding centre!

Broadly speaking, solar energy research falls into four main sections:

- passive domestic systems: water heaters, space heating and air conditioning;
- production of electricity from solar energy;
- use of photosynthesis and related processes to "fix" solar energy, and
- miscellaneous applications.

Research into passive domestic systems is now well advanced, and ranges from the development (at the S'de Boquer Desert Research Centre) of lightweight collector panels which the householder can install himself, to detailed investigations of the technical and economic problems of central

heating systems for apartment houses and other large establishments. Such a survey was carried out at the Ben Gurion University, Beer-Sheva, using the students' hostels as a pilot system.

A number of heating/air conditioning systems are being studied. At S'de Boquer, a whole line of one-room 'houses' has been erected, to permit the variation and comparison of the structural parameters involved. The underlying concept of the S'de Boquer research is that the development of the Negev should guarantee a reasonable quality of life for those who settle there; comfortable and appropriate housing is therefore all-important.

The storage element in these systems is simply a rough-fill of local stones and pebbles, which considerably reduces the cost. A somewhat similar principle has been tried at the Government Agricultural Research Station at Vulcani, for the heating of chicken-houses, but with less success; largely because chicken-house heating requires a series of peaks, rather than a steady background heat, and it is difficult to work out an economic regime of operation. Similarly, solar drying of tobacco failed to give the right leaf colour. The Vulcani team are not, however, too disappointed; the research has taught them a good deal, they consider, in the management of solar energy, and the solar drying technique might yet prove commercially viable for herbs such as oregano and mint.

Active solar energy systems, producing electricity from solar power, present a more complex problem. Economically speaking, the main problem is the cost of the silicon cells. In the USA, investments of the order of several hundred million dollars have been made in attempts to reduce the cost of the cells, and have succeeded, over the last two years, in reducing the effective cost of solar-cell electricity from \$40 to some \$12/Watt.

At the Weizmann Institute, however, a different approach is used—high-concentration arrays, using plastic Fresnel lenses to concentrate the sunlight onto small, relatively low-cost cells, and a mechanical tracking system to keep the array directed towards the Sun.

Over the last five years, considerable efforts have been made to incorporate the latest technological developments into the fabrication of high-efficiency solar cells, so that, at present, arrays of the Weizmann type can compete with small diesel generators. In the opinion of Dr Yosef Mandelkorn, by 1985, the cost of high-concentration silicon arrays will be low enough to warrant their use in self-contained urban communities away from the main centres of population.

One very interesting development

Figure (above): a large on-line Sun-tracking system for solar energy experiments at the Weizmann Institute of Science, Rehovot. The system can drive 2 m² of solar concentrators

of this kind of array, he added, is the possibility of using solar cells for the simultaneous supply of electrical and thermal (hot-water) energy, by mounting the cells on a structure of pipes through which a heat-exchange liquid flows.

In Dr Mandelkorn's opinion, use of high-concentration arrays could reduce the cost of silicon cell power generation to \$2 to \$4/Watt in the very near future—a figure which most experts would, he said, consider "realistic".

A far more radical approach to solar power generation is that of Dr Branover of the Ben Gurion University, Beer-Sheva. His project, which is supported by the Israeli Ministry of Energy, uses solar power to heat a low-boiling point liquid to about 70 to 80 °C, so that its vapour mixes with a suitable liquid metal (mercury, gallium, Wurtz metal) and accelerates it to a velocity of some 30 to 40 m/sec.

At this velocity, the liquid enters the field of a permanent magnet (about 0.5 Tesla). Depending on the circuit parameters, with this velocity and field it is possible to generate a field of about 1V with a current strength of up to 1,000 A.

Low temperature magnetohydrodynamic (MHD) generation of this kind, says Dr Branover, offers many advantages; it has no moving parts save the liquid metal, and is hermetically closed once for all. By connecting several generators in series, it is hoped to produce direct current of around 1,000 A at 10 V.

Such a power source, says Dr Branover, could be used in the chemical industry for producing copper, magnesium and aluminium. It could also be used for charging batteries for electric cars, which could change their batteries at garages in the same way that they now fill up with petrol. This would facilitate the change over from petrol-driven to electric automobiles without disrupting either the infrastructure of garages nor the fiscal system (since governments could simply tax the batteries instead of the petrol); however, this, says Dr Branover, would not be practical before about 1990, since the onus is on the automobile

manufacturers to produce a suitable vehicle.

His low-temperature MHD plant should, however, be in operation, at least at the pilot stage, by 1982; all the preliminary calculations are done, and work is now going ahead on building the model.

Another imaginative use of solar energy as a power source is based on *Dunaliella*—the only life-form capable of surviving in the Dead Sea. This alga manages to survive the high osmotic pressure by producing glycerol, which can amount to 85% of its dry weight. Possibilities of the commercial production of *Dunaliella* are being worked out both by the Weizmann Institute and the H. Steinitz Marine Biology Laboratory (Eilat) of the Hebrew University. The main problem would appear to be the harvesting of the alga; possible centrifuge methods are under investigation.

Algae production as a means of fixing solar energy is a popular subject in Israel, which hosted an international conference on the subject at Acco last September. One of the most imaginative schemes, worked out by a team from the Technion, headed by Professor Gedaliahu Shelef, uses photosynthesis, bacterial action and algae growth to purify sewage by a process of aerobic digestion accelerated by aeration and flotation techniques. The algae is recovered and used as high-protein animal feed, and the recovered effluent can be used for irrigation. A pilot plant is already in operation in Haifa; introduction of the process on a commercial scale, says Professor Shelef, could save the Israeli economy the several million dollars a year presently spent on the import of soybeans and fishmeal.

The use of essentially natural processes as energy sources seems to have a particular appeal to Israelis, both from an economic point of view, and also, as was frequently pointed out at the Intecol conference in Jerusalem last September, Israel is geographically too small a country to carry an ecological disaster or major pollution.

One such process, which is now being implemented on a pilot scale in

the Negev, is the solar pond. The original "solar lake" was discovered in 1967 in the Sinai, just south of the former frontier. It is a brackish water lake, with high salinity caused by evaporation, into which, during the winter, a certain quantity of less saline water seeps, forming a top layer. Since the lower layers are so dense, no convective mixing can occur, and accordingly, under the Sun's heat the bottom waters can reach a temperature of up to 60 °C. In an artificial solar pond, a suitable heat exchange system can be installed, and the heat extracted. The Weizmann Institute have even considered the possibility of using the Dead Sea itself as a solar lake. According to their calculations 50 square miles of the Sea would provide enough energy to double Israel's water resources by utilising the heat produced in a desalination process.

Perhaps, however, the most imaginative use of solar power is not as an energy source at all, but as a means of controlling soil-borne pathogens. In a process developed by Professor Ja'acov Katan of the Hebrew University, instead of using pesticides, with all their problems of side-effects on non-target organisms, biodegradation, and the like, the soil to be disinfected is simply covered in the summer by a sheet of plastic.

Field tests, taking samples from three layers of soil, showed that after 13 days the pathogens were killed even in the lowest layers. Block-randomised tests give dramatic evidence of the effectiveness of the method, which has already, incidentally, been adopted by some cotton farmers in the USA to control *fusarium*.

The main cost of the method is the plastic, which deteriorates in the strong sunlight and is therefore not reusable. Moreover, it is easy to apply—all the farmer has to do is to unroll the plastic and anchor it firmly.

It would therefore, says Professor Katan, be an ideal method to introduce in the third world, many countries of which share with Israel the prime requirement of any major solar energy programme—a hot climate and a clear sky. □

Red Sea muds ripe for exploitation

DEEP waters containing hot brine and metalliferous muds have been known to exist in the Red Sea since the mid-1960s. However, exploitation of this mud has been hindered by a mild dispute between Saudi Arabia and Sudan over Sovereignty of the Sea, by a lack of resources and by the absence of a suitable technology for mining it.

In May 1974 Saudi Arabia and Sudan signed an agreement on the joint exploitation of the metalliferous mud.

Under the agreement the Red Sea is divided into three zones: one extending westward from the Saudi coast to a line where the depth of water is continuously one thousand metres; one extending eastward from the Sudanese coast to a line where the depth of water is continuously one thousand metres; and a common zone lying between the two others. Each country has exclusive rights over the area between its coastline and the common zone; in the com-

mon zone both countries have equal and exclusive rights.

The agreement paved the way for exploiting the mineral wealth in the Red Sea. Almost exactly a year after the agreement was signed, the two sides established the Jeddah based Saudi-Sudanese Commission for the Development of Red Sea Resources. Each country is represented on the commission by three members; the head of each delegation being the

ministers of mineral resources. The commission is largely funded by the Saudis who hope to obtain a good return on their investment.

The commission is mainly interested in a 60 sq km area known as the Atlantis II deep. It lies midway between Jeddah and Port Sudan in the central trough of the Red Sea. It is here that the metalliferous muds are found. These muds contain 17 different metals in economic quantities ranging from zinc, silver, copper, cadmium, mercury, gold to a great deal of iron. The commission is undertaking extensive surveys and feasibility studies which are expected to be completed by 1981 at an overall cost of US \$100 million.

Before mining can begin a number of technical problems must be overcome. The Atlantis II deep cannot be mined with existing technology so the commission has had to develop its own technology for mining and processing the muds. The commission has done this with the Bureau de Recherches Géologiques et Minières of France, as technical consultants and with the assistance of the Arabian Geophysical Surveying Company, the Arab League Educational, Cultural and Scientific Organisation, the German mining company Preussag and the Universities of Hamburg and Duke.

Small mountains of the mud, which

consists of a superfine material exist in a highly saline, hot environment. The system developed to mine the mud involves agitating it to dilute it with sea water, and then sucking it up with a hydraulic pump. Special ship-borne flotation cells will collect a 5% concentrate of mud in brine. The concentrate will then be carried off to the shore for further treatment and metal extraction. The method of treatment and separation of the metals is claimed by the commission to be cost-effective with a recovery rate of 95%.

Pilot experiments on mining and the separation of metals have already been carried out and further experiments are planned. The mining system will soon be tested in the North Sea and the Mediterranean before final tests begin in the Red Sea. A Red Sea pilot test is planned for February next year.

Disposing of mining wastes has also presented a serious technical problem. Despite the increase in traffic through the Suez Canal, the Red Sea is one of the cleanest seas in the world. The commission is aware that its activities could be detrimental to the environment and sea life of the Red Sea.

The main environmental hazards will result from the diluted muds pumped up and the chemicals used in the flotation process being dumped back into the sea. It is expected that

the pollution would ultimately drift to those areas of the Red Sea that are rich in marine life. The commission is undertaking an extensive research programme, monitoring the environment and controlling the possible effects of this pollution.

The commission is aware that the mining and processing technology developed for the exploitation of the Red Sea, some aspects of pollution control technology, have been tailor made and may not be applicable elsewhere. Other Third World countries, however, can learn a great deal from the research and development activities of the commission. It has, therefore, established an information and documentation centre on the Red Sea. The centre is intended to be used primarily by Saudi and Sudanese researchers and scholars and as a facility for graduate studies. But it will also be open to researchers working on similar problems in other parts of the Third World.

Production is expected to begin around 1985, the yield being 100 thousand to 150 thousand tons per annum over the next 15 to 20 years. The present day value of located reserves in the Red Sea is US \$2.5-\$3 billion. The Saudis and the Sudanese hope to become almost self-sufficient in the minerals they extract from the Red Sea.

Nuclear power reaches the Swedish stage

A LITTLE girl is playing a recorder by a river. A monstrous, jerking man closes in on her. She looks up, smiles. "Hullo", she says, "my name is Maria. Shall we play?" She picks flowers. They throw them into the river. She holds out her hands to him. He picks her up, and throws her into the river.

At the interval, two men approach me in the foyer. Each wears a T-shirt. On one T-shirt I read "nuclear reactor"; on the other, "nuclear weapons". As they go by, I see that they are joined by a tape which reads "nuclear waste".

The drama and the facts of nuclear power: nuclear reactors as Frankensteinian monsters, and nuclear reactors as objects of discussion and debate. This is the subject of the most controversial autumn theatre Stockholm has to offer: "The Storm" ("Stormen").

Originally billed for a nine-night run, but prolonged to more than twice that by public demand, "The Storm" is no ordinary production. Nearly all of the Royal Dramatic Theatre's 350 staff members have had a hand in designing the performance, and their enthusiasm is reflected in the energy-and-the-future exhibitions in the theatre's corridors, as well as in the blinking radiation signs, whirling wind vanes and solar panels sprouting from its stately roof.

Frankenstein: a nuclear reactor on the Stockholm stage.

The audience gathers in the main theatre at the beginning and the end of the evening, to see two hearings. The first of these is being held after an accident at a nuclear reactor. Who should take the responsibility for the accident? Various people are questioned. Their answers have been woven into a script from their organisation's actual official texts. The reactor's security chief insists that no accidents can happen; the man from Asea Atom (constructor of reactors) points out that his company only made the tur-

bine, which worked perfectly and had nothing to do with the accident; the lady from the Radiation Protection Institute insists that her institute is responsible for radiation protection only when the reactors are working properly; the State Power Board man can only repeat how much the country needs nuclear power for its balance of payments. The man in the control room at the time of the accident had not followed his instructions, and he is prepared to admit that he must take some of the blame. The message is clear:

the responsibility is nobody's; there is to be one sacrificial lamb.

The crux of the play comes with the second debate: can nuclear power and democracy co-exist? The hearing continues. More witnesses are called: politicians join technocrats. Arguments fly. Again, the message is clear: the complexity of nuclear technology puts it out of the public's control. Democracy has yielded to parliamentarism: the experts rule. But this can be changed if the people demand it. Technology, they should insist, must be intelligible to those who will be affected by it. The people should stand up and fight for a non-nuclear society.

Between hearings, the audience is escorted in small groups through mazes of corridors, past theatre staff notice boards, up and down old staircases and under backdrop stores to see some of the small plays being simultaneously performed in subterranean rehearsal rooms. The play I saw transported us to Baghdad, where a delegation from the International Atomic Energy Agency providing "atoms for peace" ended up supplying the Iraqis with their own atomic bomb.

Reactions to the play have only one thing in common: passion. "Possibly the Dramatic Theatre's most important cultural contribution ever" proclaims Hannes Alfvén, Nobel laureate and nuclear power opponent. "Monstrous lies—the threat to democracy is not nuclear power, but a cynical exploitation of the people's fear of it", declares Lars Lundgren of the Central Electricity Production Board (CDL). "Two things about the play annoyed me personally", adds Bo Kumlin (CDL). "One was a very anti-science feeling: the idea that science and technology as such are bad for the people. This is a very negative approach, which really has nothing to do with nuclear power. The other was that it purposely equated nuclear power with nuclear weapons, making it very hard for the audience . . . to know whether they were talking about the one or the other."

"We have been criticised for not trying to be objective", explains Jan Oqvist, employed as ideas man for the production. "But when the theatre staff started going to see nuclear reactors for themselves, they were shocked. They could not ignore the contradiction of the heavy security precautions, while the guides kept telling them that it was all perfectly safe and that nothing could go wrong. Then they were infuriated by the attitude of some of the scientists they talked to: 'Science is our preserve—what business have you amateurs got to play with it?' We had to impart our experience. The theatre can never be neutral."

Wendy Barnaby

Rocky road to funding

THOMAS H. JUKES

THE return of rocks from the moon by the Apollo expeditions, at considerable expense, gave the geological sciences a unique and unprecedented opportunity for extraterrestrial research with all its far-reaching implications. Biologists could admire the new findings, and try not to be envious. However, *Nature* reported on 10 August, page 522, that the continued funding of moon rock research had been completely blocked by a subcommittee headed by Senator William Proxmire.

It has seemed for some years that the Senator's reach for scientific matters exceeds his grasp of their significance. However, he is apparently alert to the vote-getting potential of issues including science. In 1974, he was successful in eliminating regulations that were designed to curb the expansion of the "health food" industry into ever-widening horizons of vitamin sales. (Incidentally, it seems strange that "health foods" need such heavy supplementation with vitamins.)

The FDA had proposed to restrain the excessive promotion of megavitamin usage by requiring the proponents thereof to establish its usefulness. The curb would have hit the health food stores in the pocket by reducing sales of high-potency vitamin products. The proposal did not affect vitamin pills of lower, but adequate content, each containing 1.5 times the recommended daily allowance. Any amount of vitamins can be obtained by swallowing large numbers of such pills.

Senator Proxmire led the fight in Congress against the regulations, and he introduced a bill to stop them. The bill was opposed by all major professional groups concerned with nutrition, who opined that the "Proxmire bill" catered to the health food in-

dustry and was contrary to the public welfare. It passed the Senate by a majority of 78 to 11, greatly aided by a spectacular letter-writing campaign that was mounted by the National Health Federation. This commercially based organisation sponsors laetrile and opposes fluoridation. One of Senator Proxmire's arguments was that the recommended daily allowances for vitamins had been set artificially too low by the Food and Nutrition Board of the National Academy of Sciences so as to benefit the food and pharmaceutical industries. He said that these industries had subverted the Board by paying its way. The argument seemed strange, because if the allowances were increased, the pharmaceutical industry would sell more vitamins, and the food industry would add increased amounts to foods.

The president of the Academy wrote Senator Proxmire a seven-page letter explaining that the Board was financed solely by a US Public Health Service grant. The letter was unanswered, and when I asked the Senator why, he told me that it was the typical response of a bureaucrat who had been caught in a conflict of interest.

The newspapers help Senator Proxmire by publishing what he calls his monthly "Golden Fleece" award for wasting tax dollars. The award frequently holds research proposals up to ridicule. This is an old-time headline getter. Years ago, a Secretary of Defense, Mr Charles Wilson, announced that his department did not intend supporting research on the question of why grass was green. Once a congressman made headlines by poking fun at an investigation of the "lovelife of cockroaches". This was good for a laugh, because it was well before the search started for pheromones to be used as replacements for insecticides.

Last month Mr Proxmire's target was a \$5,000 expenditure to exercise pregnant pigs on a treadmill. His witty comment on this, as reported by Reuters, was "The folks at U.S.D.A. went hog wild on this one. As a result, the taxpayers may get stuck with a pig in a poke."

To a taxpayer, the palatial Russell and Dirksen Buildings seem at first glance to be sufficiently commodious for the U.S. Senate. Better things are planned: a new, marble, \$135 million palace from which vantage point Senator Proxmire, if re-elected, will doubtless dispense more pearls of wisdom. Perhaps he will bestow a Golden Fleece award on the US Senate.

Incipient superfluidity in normal liquid ^3He

from P. V. E. McClintock

EXPERIMENTS by D. N. Paulson and J. C. Wheatley, described in a recent issue of *Physical Review Letters* (41, 561; 1978) provide the strongest evidence yet that liquid ^3He anticipates its superfluid transition. It seems that, when the liquid is cooled towards the transition temperature T_0 , its properties first start to deviate from the behaviour characteristic of the normal (non-superfluid) liquid at a temperature which is significantly above T_0 , almost as though the liquid somehow 'knows' that it is about to become superfluid.

At sufficiently low temperatures liquid ^3He does not support ordinary compressional soundwaves because the collision mean-free-path of the quasi-particles which would carry the wave becomes longer than the wavelength of the sound itself: instead, however, there is a peculiar collisionless form of wave propagation known as zero sound. It is this phenomenon which has been investigated by Paulson and Wheatley. Their experiment amounted, in effect, to a very careful study of zero sound and, in particular, of its attenuation coefficient α_0 close to T_0 . The attenuation coefficient, which is defined by how rapidly the wave decreases in amplitude as it travels through the liquid, is known to depend accurately on the square of the temperature T when T is well above T_0 ; but, at T_0 itself α_0 starts to rise very rapidly, in fact almost discontinuously, as T is further reduced. What Paulson and Wheatley wished to ascertain was whether or not any departures from the T^2 dependence could be detected just above T_0 .

Their experimental cell consisted of a pair of quartz transducers which were used, respectively, to excite and to detect the zero sound, thus enabling measurements to be made of the attenuation which occurred within the 12.7 mm path length of liquid ^3He which separated them. The cell was mounted in a nuclear demagnetisation cryostat capable of achieving and

maintaining the temperatures near 1 mK necessary to induce the superfluid transition (the exact value of T_0 depending on the external pressure applied to the liquid). A particularly important feature of the experimental design, distinguishing it from some earlier zero sound cells, lay in the thermometry arrangements.

A paramagnetic susceptibility thermometer was used but, rather than the conventional compressed cylinder of powdered cerium magnesium nitrate (CMN) crystals, the authors used instead a cylinder of cerium lanthanum magnesium nitrate. By replacing 95% of the magnetic cerium ions by inert lanthanum ions, magnetic interactions

between the cerium ions were greatly decreased. This substantially reduced experimental uncertainties involved in converting from the so-called magnetic temperature T^* (defined on the assumption that the temperature is exactly inversely proportional to the measured susceptibility—which it is not) to the absolute Kelvin temperature T . To a good approximation, $T = T^* + \Delta$ where Δ is the required correction: for pure CMN, Δ is about 0.6 mK; whereas, for the diluted CMN used by Paulson and Wheatley, Δ was found to be 0.1 mK or less.

The importance of an accurate absolute temperature scale arose from the need to look for very small deviations from the T^2 law as T_0 was approached: using pure CMN, a small error in Δ can easily produce the illusion of such deviations by introducing a systematic error in T . For the diluted CMN, on the other hand, Δ was already so small that the possibility of spurious effects of this nature could virtually be ignored.

Some experimental results are shown in Fig. 1. The zero sound attenuation α_0 , divided by T^2 is plotted vertically, and the inverse of the temperature T is plotted horizontally. Both quantities have been normalised in such a way that they take the value unity at T_0 . If there were no deviations from T^2 behaviour above T_0 , the graph would follow the dashed horizontal line until the transition at $T_0/T = 1$ was reached, where it would then start to rise almost vertically. Clearly, the reality is far otherwise: there is a small but quite definite excess attenuation, starting well above T_0 which grows increasingly rapidly as T_0 is approached.

Comparable behaviour has also been seen, although not so clearly, in the static magnetisation (Paulson, Kojima & Wheatley, *Phys. Lett.* 47A, 457; 1974) and in the viscosity (Parpia, *et al. Phys. Rev. Lett.* 40, 565; 1978). In each case, the property seemed to start responding to the transition before T_0 had quite been reached. The 'anomalies' were, however, a good deal smaller than in the case of zero sound, and they were hard to evaluate pre-

Fig. 1 The attenuation α_0 of zero sound in normal liquid ^3He divided by the square of the absolute temperature T , plotted as a function of T^{-1} . (Both ordinate and abscissa have been normalised in such a way that they are equal to unity at the superfluid transition, where $T = T_0$ and $\alpha = \alpha_0$.) Departures of the experimental points from the horizontal dashed line indicate the extent to which the liquid anticipates its superfluid transition at temperatures above T_0 . (After Paulson & Wheatley, *op. cit.*)

P. V. E. McClintock is a member of the Department of Physics at the University of Lancaster.

cisely because of the thermometry problem referred to above.

The reason why liquid ^3He behaves in this way, apparently anticipating its transition, is probably associated with the existence of fluctuations: these may be pictured as the rapid transient formation and disappearance of tiny regions of superfluid, even when the liquid as a whole remains above T_c . In the superfluid just below T_c , α_0 is very much larger than for the normal phase, so that one consequence of such fluctuations might indeed be an 'anomal-

ously' large value of α_0 when T is just above T_c . The magnetisation and viscosity change much less dramatically below T_c , so that the effect of fluctuations on these properties just above T_c would presumably be correspondingly smaller, in agreement with experiment.

There is, as yet, no quantitative theory to describe these phenomena, but it seems probable that strenuous efforts will now be made towards this end—particularly since studies of the corresponding effect in superconducting metals have proved so rewarding.

Conservation in Madagascar

from Alison Jolly

THE first international conference organised by Malagasy scientists on the problems of conserving their unique flora and fauna was held recently in Antananarivo.* The conference was convened to deal specifically with the Malagasy lemurs, a group of primates unique to the island. The government of the Malagasy Democratic Republic has postponed such discussion for the past five years for the good reason that conflict between shifting agriculture and forest conservation is one of the country's most intractable political problems.

Madagascar is one of the world's biogeographic regions. Of its roughly 715 vertebrate species, some 575 are endemic; so are at least 80% of its 10,000 flowering plants. Six families of plants, four of birds, and five of mammals are confined to Madagascar. Intact Malagasy rainforest, deciduous woodland, or spiny desert, where 90% of all the species are unique, show us Hutchinson's "ecological theatre and evolutionary play" with a different cast of characters.

Giving the keynote address, Joseph Andrianampianina, of the Directorate of Water, Forests and Soil Conservation, described lemur hunting, and habitat destruction by axe and fire: slash and burn clearings in the eastern rainforest, forest fires for grazing land in the dry west. When man reached Madagascar little more than a 1,000 years ago, the island-continent was wholly forested. The last full aerial survey, begun in 1949 and published in 1958, showed 20% forest cover. The American states from Maine south through Virginia, with the same area as Madagascar, have almost twice as much forest as Madagascar 20 years ago. The rate of clearance has accelerated to the point where the only

intact forests will soon be those defended by national action. In spite of the scientific importance of Malagasy wildlife, and its possible tourist value, Andrianampianina concluded, "We are perfectly aware that none of our suggestions, none of our practical advice, will achieve anything . . . for the protection of nature, if the people do not have land which they can cultivate in perpetuity in order to live."

Scientific communications at the meeting fell into three groups: morphological and genetic evolution of lemurs, field studies in 'undisturbed' habitat, and papers which took up Andrianampianina's theme of conservation with its social corollaries.

Morphologists seemed to concur, for once, that the Cheirogaleinae, or primitive mouse and dwarf lemurs, form a very distinct group from the Lemurinae or true lemurs like the familiar ringtail. The same picture emerged from multivariate analysis of limb bones (C. Oxnard, J. McArdle, R. German, Chicago; F. K. Jouffroy, Museum Nationale d'Histoire Naturelle, Paris), from the pelvic girdle (C. Berge, MNHN, Paris), the skull (N. Petit-Maire, CNRS, Marseille), and fingerprint analysis (B. Rakotosamamina, Ministry of Higher Education and Scientific Research, Madagascar). This could mean that the Cheirogaleinae will eventually be elevated to family status, which would give Madagascar four primate families of its own, with the Lemuridae, the leaping Indridae, and the Daubentonidae. (Of course, *Daubentonia*, the preposterous aye-aye, may be extinct by then.) Randriamanantenina (University of Antananarivo) presented a new analysis of the subfossil genera of giant lemurs which disappeared about 1,000 years ago with the coming of man. She showed that extinct lemurs were robust in allometric proportion to their size, which suggests that there were no agile brachiators among them. Comparing

limb and vertebral indices confirms Walker's view that *Megaladapis* was a koala-like clinger, but *Paleopropithecus* may have hung upside down like a sloth. H. Hemmer (Mainz) discussed brain size in *Lemur* and W. Padushka (Vienna) the evolution of primate scent marking from ancestors like the Malagasy insectivores.

Chromosome and serum transferrin studies indicate that both *Lemur* and *Lepilemur* are in the course of active speciation (J. Buettner-Janusch, New York University; Y. Rumpel, Strasbourg; J. Andrianivo, Hôpital Gerard et Robic, Madagascar). Each is highly polymorphic in chromosome number, with some genetically isolated species such as *Lemur macaco* or *Lepilemur septentrionalis* which are no more different in morphology than the many races or local variants of interbreeding forms. Buettner-Janusch suggests that much of the molecular and chromosomal variation has arisen in the past thousand years, since the Malagasy central plateau was cleared, leaving a ring of semi-isolated lemur populations round the coast. Coulanges (Institut Pasteur, Madagascar) reviewed the literature on lemur disease. Their physiology differs from other primates: they are apparently immune to polio and to falciparum malaria. It is not known what role lemurs have in the transmission of other malaras, or whether the fact that there is no yellow fever on Madagascar is due to lemurs' immunity, to the ecology of the local *Aedes* mosquito species, or to luck.

Field studies dealt with comparative ecology and behaviour of nocturnal lemurs in a highly seasonal western forest (J.-J. Petter, E. Pages, MNHN, Brunoy), with separation of lemur, bird and insect calls by time or pitch such that each species has its own 'acoustic niche' (L. McGeorge, Duke University, North Carolina), and with foraging strategies in *Indri* (J. Pollock, University of Cambridge). Pollock's indri even draped themselves on a branch and sang their air-raid siren territorial wails in front of forty conference members, which should infuriate all naturalists who have spent days hunting indri in vain. The field work for all those studies, however, was done before the Malagasy Republic suspended research visas for foreigners in 1974. Recently M. Razarihelisoa, R. Albignac, and their students at Antananarivo University have embarked on a study of *Avahi*, the woolly lemur. *Avahi* is nocturnal, lives in pairs in well-defined territories, and eats only leaves. To judge by the conference field trip its movements are as predictable as the

*International Colloquium on Malagasy lemurs, held at Antananarivo, Democratic Republic of Madagascar, on 4-14 September under the sponsorship of the Malagasy Academy.

Alison Jolly is a Research Associate in the School of Biological Sciences, University of Sussex.

teddy-bear it resembles. The study site is an effectively protected forest, a 6-hectare remnant inside the plantation of a paper mill, which has helicopters for fire-fighting. That tiny *Avahi* population may survive, just as white sifaka and ringtailed lemur populations have remained stable since 1963 in the privately protected 100-hectare reserve at Berenty. Lemurs are relatively small and sedentary mammals, so it may be that the minimum critical size of an effective lemur reserve is modest in terms of each species. Larger scale reserves, are needed, instead, to save a representative sample of all the forest types, from rainforest to the thorn-studded, arid, *Euphorbia* forest of the south.

As for direct conservation action, Antananarivo University has just founded a field station with a reserve fenced and guarded on the Berenty model. This is a cooperative project with Yale and Washington (St. Louis) Universities, financed through the World Wildlife Fund and set up by Guy Ramanantsoa (Antananarivo), the conference organiser. After considerable difficulty in finding a local commune which would permit a reserve on its land, he at last chose a stretch of gallery forest in the south, where the local commune welcomed university involvement. This 100-hectare field laboratory is particularly important because it has adequate funds. It is, of course, trivial in scale compared to the 470,000 hectares of designated wilderness reserve which the government has no funds to protect. When Bruno Ratovomboahangy, one of Ramanantsoa's students, described the plight of the rare black sifaka, a race clearly doomed to extinction because its last shred of forest is being cleared, J. Manambolona (Antananarivo), the session's chairman, pointed round the room to four government officials and declared, "This is exactly why we are met, and this is what you must cure!"

Rabe Rafael, Director of Water, Forest and Soil Conservation, presented a detailed proposal for protection of the 580,000 ha of national parks and reserves. He asks for funds amounting to £1.2 million. Less than half that sum would be for the strict forestry needs of personnel and equipment. The other half would go toward formulation of land-use plans and to developing agricultural alternatives for people living around each reserve.

There is now increasing international awareness that the social and economic benefits of conservation are inextricably involved with any park plan. If UNEP, the IUCN, and other international bodies aid ecologically rational development in Madagascar, they could help the Malagasy Republic to save a unique portion of the world's scientific

heritage. If not, the Malagasy will conclude that rich countries only find money to fly their own scientists to conferences. Western knowledge will seem as partial as the expertise of "the man who wears a loincloth that is falling to pieces—he knows exactly how to put it on and how to take it off."

And if nothing is done, the peasants who now roll back the forest will have the same problems in 10 years' time that they do today: eroding watersheds, sterile soil, dwindling firewood supplies. The only answer then will be planted pines or eucalyptus. The option of saving the Malagasy forest communities and hundreds or even thousands of Malagasy species will be gone. □

Halophilic ribosomes

from Richard Brimacombe

COMPARISON of ribosomes from different organisms provides a promising approach to the problem of understanding ribosome structure and function. Several laboratories are engaged on amino acid and nucleic acid sequencing of ribosomal components and are gradually piecing together the information to make such comparisons. One example is recent work on the ribosomal proteins of the extreme halophilic bacterium *Halobacterium cutirubrum* which has come up with some intriguing results. Matheson *et al.* (in *Halophilic Microorganisms* (ed. Caplan) Elsevier/North Holland Biomedical Press (in the press)) have compared the amino acid sequences of the acidic ribosomal proteins—the A proteins—from a variety of halophiles ranging from moderate to extreme. These A proteins are those that seem to correspond with proteins L7/L12 in *Escherichia coli*.

The ribosome of *H. cutirubrum* has been of interest for some years. Whereas the RNA and protein components are similar in size and number to those of *E. coli*, the proteins are very much more acidic (Bayley & Kushner *J. molec. Biol.* 9, 654; 1964). It follows that two-dimensional gel electrophoresis gives little clue to which *H. cutirubrum* proteins correspond to which *E. coli* proteins, and the two organisms are sufficiently unrelated that comparison of N-terminal amino acid sequences is also not very helpful. So Matheson *et al.* have restricted their comparative study to the proteins apparently equivalent to *E. coli* L7/L12 (L20 in *H. cutirubrum*), and to those proteins which bind to

5S RNA. *E. coli* proteins L7 and L12 differ only in the presence of an N-terminal acetyl group on L7, they are distinguished by being the most acidic proteins in the 70S ribosome, and the only proteins present in multiple copies (three to four per 70S). These proteins are functionally important, notably in GTP-dependent processes, and are interchangeable between ribosomes from unrelated organisms such as *E. coli* and yeast (for review see Möller in *'Ribosomes'*, Cold Spring Harbor Press, 711, 1974).

The complete amino acid sequence of *E. coli* L12 (EL12) has been known for some time (Terhorst *et al. Eur. J. Biochem.* 34, 138; 1973), and Matheson *et al.* find that, whereas the amino acid sequences of the equivalent proteins from moderate halophiles are very similar to that of EL12, the sequence of L20 from *H. cutirubrum* (HL20) (which is now complete except for an unordered highly acidic region between residues 78 and 106) has some very interesting similarities and differences. A simple comparison of the amino acid compositions shows that in HL20 the lysine content has dropped drastically from 13 residues to 1, and there is a corresponding increase of 7 to 22 in aspartic acid residues. 60% of the protein is in fact composed of aspartic acid, glutamic acid and alanine. Further, methyl lysine (present in EL12) is absent, and the valine content is reduced, whereas at the same time two tyrosine residues (absent in EL12) make an appearance. Nevertheless, despite these very large differences, there are still distinct regions of homology between the *E. coli* L12 and *H. cutirubrum* L20 sequences.

The first of these is a region of about 18 amino acids near the N-terminus of HL20 (positions 12–30), which shows a high degree of similarity to EL12, not in the N-terminal region of the latter, but in the middle of the sequence (positions 46–62). Another characteristic region, which is very rich in alanine, is observed in the *H. cutirubrum* protein (positions 57–67, with nine alanines). This region is C-terminal with respect to the homologous region just mentioned, whereas the corresponding alanine-rich region in EL12 (positions 34–42, with eight alanines) is on the N-terminal side. Thus the two homologous regions are inverted, and the whole N-terminal region of the *E. coli* protein seems to have completely vanished from the *H. cutirubrum* protein. In addition the basic area of EL12 (positions 57–84) has disappeared in HL20, the latter in turn showing a highly acidic C-terminal region (positions 70–112) which has no equivalent in EL12.

The sequence of *H. cutirubrum* L20

Richard Brimacombe works at the Max-Planck-Institut für Molekulare Genetik, Berlin-Dahlem.

shows less homology with the moderate halophiles than it does with *E. coli*, suggesting that the extreme halophile has not evolved from the moderate halophiles. Indeed a comparison with the N-terminal sequences of the corresponding N-terminal sequences from two eukaryotic organisms *Artemisia salina* and *Saccharomyces cerevisiae* (Amons *et al.* *FEBS Lett.* **81**, 308; 1977) shows a high degree of homology with HL20 in the first 11 residues, including the two tyrosine residues mentioned above. It seems therefore that the extreme halophile has both pro and eukaryotic character, an idea which is supported by the studies on the N-terminal sequences of the 5S RNA-binding proteins reported by Matheson *et al.* as well as by the sequence of the *H. cutirubrum* 5S RNA itself. Matheson *et al.* draw attention to the recent work of Magrum *et al.* (*J. molec. Evol.* **11**, 1; 1978), which places the extreme halophiles in the Archaeobacteria, primitive organisms which are little related to either pro or eukaryotes.

The amino acid sequence data are interesting in themselves, but there is another aspect of the *H. cutirubrum* ribosome which is equally important in

comparative studies, namely the halophilic property itself. *H. cutirubrum* ribosomes require at least 3.4 M KCl and 100 mM magnesium for stability, a condition under which 'normal' (that is *E. coli*) ribosomes would lose a substantial amount of their protein. Conversely, under the low salt conditions used for protein synthesis with *E. coli* ribosomes, the *H. cutirubrum* ribosome loses much of its protein (Bayley *J. molec. Biol.* **15**, 420; 1966). L7/L12-type proteins have a very high α -helix content, and have alanine-rich sequences similar to those in motile proteins (Amons *et al.* *FEBS Lett.* **86**, 282; 1978). In the case of HL20, the instability of the ribosome at low salt concentration can be at least partly related to this factor, since Matheson *et al.* find that HL20, unlike EL12, loses most of its helicity at salt concentrations below 2 M.

Thus, *H. cutirubrum* L20 is a protein which is part eukaryotic, part prokaryotic; the prokaryotic region of the amino acid sequence is back-to-front, and the protein has to function in a ribosome whose salt requirements are upside-down. The system offers fascinating possibilities for comparative studies of structure and function. □

Plant cells without walls?

from Jeremy Burgess

ISOLATED plant protoplasts are emerging slowly from their former state as an interesting curiosity and a subject for speculation to a new level of usefulness as a research tool, with their main application in virology and cell wall studies. Protoplasts are particularly valuable to the plant virologist as synchronous infection of a high percentage of a population can be easily achieved. This allows the study of the sequence of events as an infection develops in a way which is all but impossible using whole plants. For cell wall studies, protoplasts offer a rare chance of access to a naked plant cell plasma membrane which will, in some species at least, produce a functioning wall structure after only hours or days of culture.

One assumption underlies all this work on protoplasts, and it is now being brought into question. This is that a protoplast behaves as a plant cell without a wall. Mechanically this definition is certainly correct, but is it accurate in a biological sense? If it is not, and results obtained with protoplasts cannot be applied to whole plants, then the usefulness of the

protoplast as a model system is undermined.

The problem arises out of the way in which protoplasts are prepared. In brief, a tissue such as a leaf is first immersed in a concentrated solution of a sugar to which the plasma membrane is impermeable. This causes the protoplast to shrink away from the wall which bounds it, as water is withdrawn by osmosis. Once plasmolysis has occurred, the wall is enzymatically digested away.

The protoplasts are released into suspension as individual units stabilised against bursting by the sugar solute. So during its preparation the protoplast has been partially dehydrated; the connections between adjacent cells in the tissue, and between each cell plasma membrane and its surrounding wall have been severed and the cell wall has been removed. Naturally it was the third of these processes which concerned early workers with protoplasts. Now it seems that not enough attention has been paid to the effects of the other two.

Several recent papers have cast doubts on the assumption that freshly isolated protoplasts behave simply as plant cells without walls. Ruesink (*Protoplastes et fusion de Cellules*

Somatiques Vegetales, 41, CNRS, 1973) has shown that leucine uptake by plasmolysed protoplasts is drastically inhibited compared with intact cells. Racusen, Kinnersley and Galston (*Science* **198**, 405; 1977) examined electrical potentials in normal and plasmolysed tobacco leaves as well as protoplasts. They were able to show that plasmolysis results in the normal negative potential within the cell being converted into a small positive one. If the protoplasts were cultured for 10-14 days, those which reformed a cell wall also regained the negative potential. By contrast, protoplasts of maize which failed to produce a functional cell wall in culture also failed to regain the normal negative potential (Kinnersley, Racusen & Galston *Planta* **139**, 155; 1978). Changes in levels of protein synthesis and photosynthetic rates also occur in plasmolysed cells. These effects of plasmolysis on the general vitality of protoplasts are not immediately reversed. Premecz *et al.* (*Plant Sci. Lett.* **9**, 195; 1977) used RNase levels as a measure of response to stress and found that the concentration of plasmolysing solution used affected the time taken for the recovery of normal physiology. It seems clear that the initial plasmolysis and the subsequent culture in a concentrated sugar solution both present the protoplast with a stress which alters much of its biochemical behaviour compared with the normal plant cell. Thus freshly isolated protoplasts should not be regarded as plant cells without walls, but as a stressed system requiring a recovery period. For example, we have shown the need for such recovery period in the case of cell wall growth on tobacco leaf protoplasts (Burgess *et al.* *Planta* **139**, 85; 1978). Although on first isolation an 8-hour lag precedes visible wall formation, subsequent removal of this wall without imposing additional osmotic stress on the protoplasts allows a new wall to begin to form within 12 minutes.

There is no doubt that in the long term (a period measured in days rather than hours), protoplasts from many sources can completely overcome the effects of osmotic stress. Whole plants have been grown from single protoplasts in a handful of species, and many others will regenerate walls and divide, even if the cells subsequently fail to differentiate into organised tissue. However, most of the current interest in protoplasts is centred on the initial minutes or hours following isolation. This is the period when they are amenable to virus infection, when fusion frequencies are at their highest, and when the first cell wall components begin to be secreted across the membrane. That this is a period of high

Jeremy Burgess is at the John Innes Institute, Norwich.

stress for the protoplast should not be overlooked. One area of growing interest is the isolation of the plasma membrane to examine its properties with regard to the synthesis of cell wall components, and also its interaction with virus particles. For results from this kind of study to have meaning in the context of the intact plant cell, allowance must be made for the effects of osmotic stress and dehydration. At present there seem to be two ways of minimising these difficulties. The first is to use a second enzyme treatment on protoplasts which have recovered for a few hours in culture. This approach, however, assumes that the protoplasts will recover. The second way might be to ensure that the cell is not so greatly stressed initially. Colman and Mawson (*Z. Pflanzenphysiol.* 86, 331; 1977) have found that gradual plasmolysis of leaf tissue is necessary for the isolation of photosynthetically active cells. Such a refinement in technique applied to protoplast isolation might well increase the range of species which will respond to culture. Any improvement in the physiology of freshly isolated protoplasts is to be warmly welcomed. □

Nucleon-nucleon interactions

from a Correspondent

THE study of the forces between free nucleons, at energies not much greater than their rest masses, falls between the present interests of nuclear structure and of elementary particle physics. Administratively this is awkward and in Britain nucleon physics is neither popular nor lavishly funded. However, since the 'meson factories' in several other countries began operating a few years ago there has been a resurgence in studies of this fundamental interaction, which is now sufficiently well understood that we are on the verge of an accurate and coherent account of the properties of light nuclei, and of the simplest processes of meson production. These facts, which had been hinted at a year ago at the Vancouver Conference on the Nucleon-Nucleon Interaction, emerged clearly at a recent meeting in Graz*.

At all energies up to about 400 MeV proton-proton elastic scattering is accounted for by the exchange of virtual mesons, together with a set of unambiguous and well-determined phase shifts in the S and P partial waves.

The fine details of this phenomenology are due to measurements at small scattering angles by R. Hess's group from the University of Geneva, who have measured a variety of spin-dependent variables at SIN, Switzerland; and from similar measurements, over a wider angular range, performed at TRIUMF, Vancouver, by the BASQUE group (D. V. Bugg *et al.*; Queen Mary College, London; University of Surrey; Universities of British Columbia and Victoria). So well are these data described by boson exchange potentials (as developed, for example, by R. Vinh Mau's group at IPN, Orsay) that, in the opinion of G. H. Thomas (Argonne National Laboratory) no further measurements of this type are required.

Until very recently the corresponding neutron-proton data have been of poor quality, the experiments being more difficult and the available neutron beams less intense. At Graz, new measurements of triple scattering parameters were reported by the BASQUE group (D. V. Bugg *et al.*; and of the differential cross section for charge exchange, by both E. Rössle's University of Freiburg group, working at SIN, and a LASL/Texas A & M/University of Texas team at LAMPF, Los Alamos (B. E. Bonner *et al.*). The remarkable agreement between the two sets of cross sections disposes of the long-outstanding uncertainty about this quantity. The quality of these data, and of the BASQUE measurements, is now as good as the proton-proton data, and illustrate the capabilities of the accelerators at TRIUMF, SIN and LAMPF.

The BASQUE measurements have been incorporated in a number of partial wave analyses, and as R. A. Bryan (Texas A & M) showed, not only are the isosinglet phases now unique below 400 MeV, but the theoretical interpretation has altered significantly in the past year to give excellent agreement with the new data. This is seen, not only in the work of Vinh Mau's group, presented at Graz, but also in some recently-published work by the University of Florida group (Veda & Green *Phys. Rev. C* 18 337; 1978). Likewise, near 50 MeV, a careful set of measurements by F. P. Brady *et al.* (University of California, Davis) has clearly exposed the incorrectness of earlier data, which had previously been an embarrassment to the theoreticians.

With such excellent understanding of elastic nucleon-nucleon scattering, the way is now open to incorporate these theoretical models into the potentials used in nuclear structure calculations. This was made clear in a lucid review by K. Hollinde (Bonn

University). Incidentally, the perennial fear that off-mass-shell effects may dominate such many-body systems seems groundless; the considerable effort devoted to nucleon-nucleon bremsstrahlung has failed to turn up any evidence for gross departures from elastic amplitudes. Though off-mass-shell effects exist (they are needed, for example, to account for the cross-section for the capture of thermal neutrons on hydrogen), they are clearly weak at the energies considered here.

At higher energies, uncertainties multiply. Are there resonances in one or more partial waves, for example the $^3F_2$ and $^1D_2$, as N. Hoshizaki (Kyoto University) has suggested in a recent preprint? The phase-shift analyses are ambiguous above the inelastic threshold. Using a coupled channel approach, E. Lomon (Massachusetts Institute of Technology) was able to relate the BASQUE data below 500 MeV to possible resonances above this energy. Di-baryon resonances can appear in quark models, and this was discussed in several contributions, such as those of J. J. de Swart (Nijmegen) and C. de Tar (MIT). What is needed are better experimental data on spin-dependent amplitudes near 1 GeV, and so far only the ZGS at Argonne has provided this. The untimely shutdown of the ZGS next year will leave Saturne II, the revamped accelerator at Saclay, alone in this field, and the nucleon-nucleon programme there, under F. Lehar, should be of great interest.

The key to our understanding lies in the inelastic processes. J. A. Niskanen (University of Helsinki) has developed a model of pion production in p-p scattering which goes well beyond the simple Mandelstam model of 25 years' standing, by incorporating explicit isobar components into the nucleon configuration. G. Jones (University of British Columbia) reported on measurements from TRIUMF which were in strikingly poor agreement with Niskanen's model. But Mandelstam's model itself is inherently unsatisfactory; it predicts that pion production in n-p collisions is due only to the isovector part of the amplitude. E. Rössle's group presented data taken at SIN which seem to contradict this, though the experiments, and their interpretation, are difficult. Their results, and those of Jones, also show compelling evidence for d-wave pion production, even very close to threshold.

If the scattering states of two nucleons are so well understood, why is the admixture of D-state in the bound system, the deuteron, so poorly known? The answer is that the D-state arises from a tensor coupling, which is due to the exchange of rather heavy

*The 8th International Conference on Few Body Systems and Nuclear Forces was held on 24-31, August in Graz, Austria.

mesons which evoke short range forces; and the interaction at small distances (≤ 0.8 fm) is not well understood. M. Fiedeldey (Pretoria) showed that several ingenious suggestions for enhancing the experimental sensitivity to the D-state were impracticable, though D. Roger *et al.* (CEN, Saclay) showed that the quasi-free electron scattering experiments now command the accuracy needed for the task. It remains a tantalising problem. Neutron-deuteron backward scatter-

ing was studied by Bonner's and Rössle's groups at Los Alamos and SIN. Their data again agreed well, and the interest here was in a departure of the cross section from a smooth exponential near 180° . This unexpected behaviour occurs between 380 and 650 MeV. No doubt by the next Conference in this series, scheduled for 1980 at Eugene, Oregon, explanations will have been proposed; new puzzles will also have arisen in this exciting, and exacting, field. □

Rats, pigs and men in New Guinea

from Robert M. May

MAN'S impact on the New Guinea highlands dates back five or six thousand years, when widespread development of a shifting slash and burn agriculture led to substantial forest clearance, and, at the same time, the domestic pig was introduced (Bulmer *J. Soc. Océan.* 31, 7; 1975). Over the subsequent millennia, patterns of sedentary settlement gradually emerged. Major disturbance of habitats is, however, probably relatively recent, stemming from the introduction of the sweet potato (*Ipomoea batatas*) as a major food crop some 300 to 400 years ago; this innovation led to increases in population density and to the development of intensive pig-keeping at higher altitudes.

The most conspicuous change wrought by human activities in the New Guinea highlands is the replacement of forest by grassland, maintained by intermittent burning. These increasing areas of man-made grassland exist in a flux of various successional stages, as old gardens or village areas are abandoned and new ones created. The associated long-term changes in the distribution of animal species are shown by recent archaeological studies. One revealing study is from a site at Aibura, in the Eastern Highland Division, where it can be seen that over the past 1,000 years the forest-dwelling phalangerines (for example, *Phalanger* or cuscus species) have declined while the grassland pademelon (*Thylogale*, a relative of the rock-wallaby) has concomitantly increased (White, *Ol Tumbuna: Terra Australis* No. 2, Australian National University, 1972).

A particularly detailed account of the present-day distribution patterns of seven species of terrestrial rats in relation to the changing habitat in the New Guinea highlands has recently been given by Dwyer (*Aust. J. Ecol.* 3,

213; 1978). The seven species all belong to the Old World family of murid rodents, four from the genus *Rattus* and three from *Melomys*, as tabulated below. The 'productivity index' is a measure of the intrinsic capacity for population growth of the species, which Dwyer computes by multiplying the mean litter size by the average proportion of females (above minimum adult weight) that are in breeding condition. By thus using the proportion of adults that are breeding, Dwyer takes some account both of the number of litters per year and of the age structure; the quantity is, moreover, weighted to allow for differences between wet and dry seasons.

Species	Productivity index
<i>R. exulans</i>	2.10
<i>R. ruber</i>	1.74
<i>M. rufescens</i>	1.18
<i>R. verecundus</i>	0.94
<i>M. levipes</i>	0.60
<i>R. niobe</i>	0.42
<i>M. rubex</i>	0.35

As a very crude generalisation, we might expect the successful species in the relatively more disturbed and unpredictable grassland habitat to tend towards the 'r-strategy' of "high reproductive rates, short life spans, large population size, . . . and broad, often cosmopolitan distribution" (Grassle & Saunders *Deep Sea Res.* 20, 643; 1973), while the successful species in the relatively undisturbed and predictable forest habitat may tend towards the opposite 'K-strategy' (for more full exposition of these notions, see *Nature* 257, 737; 1975; 267, 394; 1977). Indeed Felming (*Ecology* 55, 555; 1974) has interpreted the life history strategies of two species of heteromyid rodents in Costa Rican rainforests in this light: *Liomys salvini* in the seasonal highland

forest as an r-strategist and *Heteromys desmarestianus* in the season-free lowland forest as a K-strategist. Similarly Freeland (thesis, Queensland University, 1972) has suggested that two murids in a subtropical Eastern Australian rainforest coexist by virtue of *Rattus fuscipes* exploiting an r-strategy keyed to environmental features that are unpredictable while *Melomys cervinipes* is adapted to relatively predictable features. If these simple ideas are to apply to Dwyer's more complicated seven-species system, we expect the habitats to manifest a decreasing degree of disturbance as we run down the species list in the table above; that is, we expect the 'productivity index' to be significantly larger in more disturbed habitats.

Dwyer shows this is indeed so. His extensive trapping studies in the Mt Erimbari-Mt Homo region at the western boundary of the Eastern Highland Division of Papua New Guinea show that the short grass communities (which are created and sustained by man) support only *R. exulans*. Notably, this is the only species on the list that also lives in houses. *Miscanthus* communities represent a later successional stage that is still short grass, and they are also largely under human control; here are found *R. ruber* and *M. rufescens*. *R. verecundus* and *M. levipes* are found in the extensively disturbed oak-dominated forests of Mt Homo, and *R. verecundus* and *M. rubex* occur together in the lower and more disturbed forests of Mt Erimbari; *R. verecundus* is more tolerant of areas regularly disturbed by pigs. High on Mt Erimbari, *M. rubex* and *R. niobe* are found together where disturbance by humans and pigs is least. The few trappings of *R. niobe* below 2,400 m were from well-protected sites. *R. niobe*, in particular, seems to need dense cover of the kind that is incompatible with piggly attention; the existence of this species elsewhere in high (and undisturbed) grassland and in forests at lower altitudes shows that neither altitude nor vegetation alone confine it within the narrow bounds observed in Dwyer's study area. Other aspects of the distributional ecology also fit the scheme: the density of *R. exulans* in grassland was 20 per ha, and of *R. niobe* and *M. rubex* on an equal grid in mixed forest were 8.0 and 4.6 respectively; the mean monthly survival probability for *R. exulans* in grassland is around 0.77, and for *R. niobe* and *M. rubex* in mixed forest it is 0.90 and 0.92 respectively. In short, these gross patterns of distribution correlate remarkably well with the 'productive index' tabulated above. Insofar as there are discrepancies, they are that for a ranking based on habitat, *R. verecundus* might rank below *M.*

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

levipes, and the reclusive *R. niobe* below *M. rubex*; these departures are easily rationalised by appeal to differences between genera (for example, each *Melomys* is larger than its *Rattus* partner)

Additional support for the idea that the distribution patterns are governed by the amount of disturbance by man and pigs comes from the archaeological record. White's (*op. cit.*) excavations have shown a marked increase in the representation of small rodents in the upper horizons of his site. Tooth measurements suggest that the three species present are *R. niobe*, *R. exulans* and *R. ruber*; of these, the first is found only in lower levels, the second only in the top level, while the third increases over time in step with increasing signs of human activity.

Dwyer concludes "that the local diversity of small terrestrial rodents in rain forests of densely populated areas of the New Guinea highlands was higher in the past than it is today and that reduction has been a consequence of habitat disturbance by men and pigs producing a smaller, less continuous, area of rainforest and simplification of ground cover. The pattern of local species distributions is now dominated by gross disturbance effects with the more opportunistic of rainforest species found in the most disturbed rainforests. Some species may have dropped out of local faunas" He also suggests that some aspects of the distribution patterns of the montane avifauna of New Guinea (as extensively studied by Diamond and others) may be associated with recent disturbances rather than with 'long term' 'island equilibrium' effects. In common with many other workers, Dwyer sees disturbance as important in promoting and maintaining species diversity, essentially because it enlarges the number of different roles in the evolutionary play. But severe disturbance, of a kind outside the evolutionary experience of the ecosystem, will make for less diversity.

The asthenosphere as point defect zone

from Peter J. Smith

At depths in the Earth of somewhere between 75 km and 250 km there is a layer perhaps some 75–150 km thick in which seismic velocity is slightly lower, and seismic attenuation is rather higher, than in the regions immediately above and below. Any uncertainty implicit in this statement arises because the depth and thickness of the layer, which may in any case be variable,

have not been determined everywhere and because, even where experiments have been carried out, the boundaries of the layer are often diffuse. Nevertheless, there seems little doubt that this 'low velocity layer' exists in some form beneath most of the Earth's surface. Moreover, the layer is now usually equated with the asthenosphere, the semi-mobile zone which allows the rigid tectonic plates of the overlying lithosphere to move.

But accepting the identity of the asthenosphere and the low velocity layer, what is the physical cause of the mobility, the lower velocity and the higher attenuation? The majority answer is partial melting of peridotite. Suggestions about the nature of the cavities in which the melt fraction supposedly resides have included spherical pores, coin-shaped cracks and tubular channels; and estimates of the amount of partial melting accordingly required to account for the seismic observations have ranged from about 6% to 0.1%. Whatever the cavity shape, the degree of partial melting required is apparently low; and so if the low velocity zone were purely a static phenomenon there would be little to choose between models.

The reality is more complicated, however, for the molten material can evidently flow, which means that in at least some parts of the asthenosphere the melt cavities must be interconnected. And that seems to pose quite a problem. For according to Shaw (*Geophys. Res. Lett.* 5, 629; 1978), Walker *et al.* (in press) have investigated the stability under gravity of a melt–solid system with interconnected porosity and have thus shown that for tubular channels, instability will arise if the melt fraction exceeds 0.1% (which compares with the roughly 1% required to explain the seismic observations). Above 0.1% the melt segregates and rises from the solid in less than 10⁷ yr. Walker and his colleagues therefore conclude that the low velocity layer is either a temporary phenomenon which just happens to be well developed at the moment or a "dynamic system with a melt fraction above their calculated limit of long term stability through which melt must flow continually at a substantial rate, in fact, at a rate which is probably unrealistically high".

Of course, many assumptions are involved, any one or more of which may turn out to invalidate the Walker model as a reasonable semblance of reality. Nevertheless, at the very least the results are such as to suggest that partial melting should not be accepted

Peter J. Smith is a Reader in the Department of Earth Sciences at the Open University.

too readily, as, indeed, some workers have long realised. Guegnen and Mercier (*Phys. Earth Planet. Interiors* 7, 39; 1973), for example, listed several other possibilities and concluded that the seismic properties of the low velocity layer could in theory be as well explained in terms of viscous grain boundary relaxation or dislocation–impurity interactions.

Unfortunately, there is little experimental data to support either of these particular solid state processes as a cause of the asthenosphere; but Shaw has now added one phenomenon for which there is some empirical (and theoretical) support: namely, the presence of point defects. Shaw himself (*J. Phys. Chem. Solids* 35, 911; 1974) has shown that in the B1 phase of silver iodide, variation in the concentration of lattice point defects leads to a very rapid decrease in sound velocity with increasing temperature and an equally rapid increase with increasing pressure. The magnitudes of defect-produced velocity changes in materials likely to be important in the Earth (such as silicates and oxides) are far less well known and may in any case be different for different types of defect (Frenkel defects, Schottky defects for example). But Shaw has little difficulty in showing that taking into account the probable relative temperature and pressure effects in materials and the variation of temperature and pressure in the Earth, a seismic velocity anomaly in the Earth would be expected in the depth range 50–250 km—precisely where it is observed.

Considering the uncertainties involved in Shaw's theoretical development, this agreement is amazing. And it is all the more encouraging in that defects are known to facilitate material transport, thus enhancing flow and leading to a decrease in apparent viscosity. If Shaw is right in his thinking, the presence of point defects offers just as reasonable an explanation of the low velocity layer–asthenosphere as does partial melting, although to prove the point there will have to be far more experiments or probable Earth materials at the appropriate temperatures and pressures. □

DNA polymerase and mutation

from Bryn Bridges

THE underlying importance of damage to DNA and its mutagenic consequences in the production of cancer and certain heritable diseases becomes steadily more apparent, and it may well extend to such superficially unrelated

diseases as atherosclerosis and certain neurological conditions. The steps by which damaged DNA generates permanently altered nucleotide sequences are, however, obscure in mammalian cells. The question is probably closest to resolution in bacteria where there seems to be an intriguing interaction between DNA damage and the fidelity of DNA polymerases.

Ultraviolet light is commonly used as an experimental DNA damaging agent and initiates mutagenesis through constitutive or inducible pathways depending on the circumstances. The existence of this inducible pathway, proposed and termed 'SOS' repair by Miroslav Radman, is best illustrated by the fact that UV-irradiation of bacteriophages λ or ϕ X174 leads to the production of mutations only if the phages are plated on bacteria that have themselves been UV irradiated or given some other 'inducing' treatment.

A mechanism for the action of DNA polymerases in ultraviolet mutagenesis has now been proposed by Radman's group (Villani *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 3037; 1978) who have shown that photoproducts produced in the DNA of ϕ X174 by ultraviolet constitute a block to DNA replication by cell-free extracts of *E. coli* operating either through DNA polymerase I or III. (Recent studies have pointed towards the role of DNA polymerase III in bacteria as the mutagenic enzyme, particularly in the inducible pathway (see Bridges & Mottershead *Molec. gen. Genet.* **162**, 35; 1978)). In experiments with purified DNA polymerase I (large fragment) they further showed that DNA synthesis on an irradiated ϕ X174 primed template was accompanied by a large turnover of nucleoside triphosphates into monophosphates, in contrast to synthesis on an unirradiated template.

DNA polymerase I large fragment lacks 5' to 3' exonuclease activity but retains both polymerising and 3' to 5' exonuclease activities. The latter is believed to act as a 'proof-reader', excising newly incorporated terminal bases which are not paired correctly with the template base. Villani *et al.* suggest that ultraviolet photoproducts in the template strand do not prevent incorporation by the polymerase function but that the bases incorporated opposite photoproducts are registered as mismatched and are immediately excised by the proof-reading exonuclease. The net result is that nucleoside triphosphates are converted to monophosphates with no DNA chain elongation, a condition termed polymerase 'idling'. They further suggest that newly-incorporated mismatched

bases could persist and be seen as mutations if SOS induction involved the inhibition of the proof-reading function so that chain elongation could proceed beyond the photoproduct and its potentially mismatched partner. In support of this they give evidence that AMV reverse transcriptase, an error-prone DNA polymerase devoid of any exonuclease activity, is both highly prone to insert wrong bases and replicates UV-irradiated ϕ X174 DNA far above the level of *E. coli* DNA polymerase I.

The findings of Villani *et al.* suggest a possible signalling mechanism for triggering the SOS inducible pathway. SOS mutagenesis in *E. coli* is dependent on the *recA*⁺ gene and it has been thought to be similar in its operation to other *recA*⁺-dependent phenomena such as prophage induction. The *recA*⁺ protein is produced in substantial amounts after ultraviolet irradiation and seems to act in prophage induction by carrying out proteolytic cleavage of the λ repressor. Villani *et al.* suggest that the nucleoside monophosphates produced by idling polymerases may well be the initial inducing signal leading to enhanced production of *recA*⁺ protein and thus to the cleavage of λ and other SOS repressors.

Another, simpler possibility is apparent, however, if we consider the recent work of Byrnes *et al. (Biochemistry* **16**, 3740; 1977) who have shown that nucleoside 5'-monophosphates inhibit specifically the 3' to 5' exonuclease but not the polymerase function of DNA polymerase I, and of Que, Downey and So (*Biochemistry* **17**, 1603; 1978) who have further produced evidence that the nucleoside 5'-monophosphates bind at the primer terminus site for the 3' to 5' exonuclease activity. On the basis of their observations one might argue that SOS mutagenesis induction might be more simply explained as follows. Arrival of a photoproduct at the replication fork causes polymerase III idling and accumulation of nucleoside monophosphates. These in turn directly inhibit the 3' to 5' exonuclease function ('induction') and allow chain elongation to continue with any mismatched bases (both opposite the photoproduct and elsewhere) persisting as mutations. Return to high fidelity replication would occur after normalisation of the nucleoside monophosphate pool. The elementary hypothesis of direct control by nucleoside monophosphate levels suggested here does not, however, have any obvious requirement for repressor cleavage by the *recA*⁺ protein. Although it may seem heretical, perhaps the possibility should be considered that the *recA*⁺ protein does not act proteolytically in ultraviolet mutagenesis but rather interacts directly at the DNA level to

'stabilise' the photoproduct-primer terminus configuration so as to allow polymerase idling. Consequent elevation of nucleoside monophosphate levels would then result in direct inhibition of the 3' to 5' exonuclease function and this in turn would lead to mutagenesis and survival. Certainly a constitutive level of the *recA*⁺ protein exists and the protein is known to bind to single-stranded DNA. Furthermore the γ -irradiation resistance conferred by the *recA*⁺ gene seems to be independent of protein synthesis and does not involve inducibility. Could this also be true for ultraviolet mutagenesis? Such an explanation, while based on slender experimental evidence, would seem to merit consideration, if only because of its simplicity. One would still have to find a role on either hypothesis for other genes (*lexA*, *lexC*, *umuC*, and *recB uvrD*, for example) which affect ultraviolet mutagenesis.

Whether or not the postulated inhibition of the proof-reading exonuclease function by nucleoside monophosphates is direct or indirect will doubtless become clear in the not too distant future. The concept of polymerase idling proposed by Radman's group is, however, very plausible and should stimulate the necessary experiments, particularly those designed to reveal whether it occurs *in vivo* as well as with the purified enzyme fragment. Also to be resolved is the question of whether DNA polymerase III behaves *in vivo* the way the polymerase I fragment behaves *in vitro*, and the question of constitutive mutagenic repair should this, as seems likely, also be mediated by polymerase III. Does this also involve inhibition of the proof-reading function and if so, how?

A hundred years ago

CAPTAIN PATTERSON, Superintendent of the U.S. Coast Survey, has lately initiated a very important undertaking in connection with the work of the Survey, namely, in determining the extent and position of the oyster beds of the Chesapeake Bay, primarily with reference to the formation of oyster reefs, and their interference with navigation, but broad enough in its scope to serve as the basis of a critical investigation of the whole subject of the oyster fisheries and oyster culture in the United States. The work is being prosecuted in the Chesapeake Bay by the Coast Survey Steamer *Palinurus*, Mr. H. J. Rice, formerly of Johns Hopkins University, looking more particularly after the natural history features, such as the embryology and development of the oyster, &c. From *Nature* **18**, 17 October, 653; 1878.

Steroid-induced meiotic division in *Xenopus laevis* oocytes: surface and calcium

Etienne-Emile Baulieu*, François Godeau*, Michel Schorderet†
& Sabine Schorderet-Slatkine‡

† Département de Pharmacologie, Ecole de Médecine, Université de Genève, Switzerland

‡ Station de Zoologie expérimentale, Université de Genève, Switzerland

Progesterone reinitiates meiotic maturation in Xenopus laevis oocytes. Evidence is reported which indicates that the steroid acts at the level of the cell surface and suggests that an induced change of Ca^{2+} distribution triggers in turn a cascade of cytoplasmic events including protein synthesis and germinal vesicle (nucleus) breakdown. These novel features of steroid hormone action in amphibian oocytes are discussed in relation to presently accepted views of the mechanism of action of steroid hormones in somatic cells.

IN TARGET cells, hormone-receptor complexes interact with an effector structure according to two major patterns. The first one, for polypeptide hormones and neuromediators, involves interaction at the plasma membrane level influencing membrane enzyme(s) (for example, adenylate cyclase) and/or cation transfer system(s). In the other case, steroid and thyroid hormone-receptor complexes interact in the cell nucleus with elements of the gene expression machinery as yet poorly defined, and probably modify transcription. We propose here that progesterone action on *Xenopus laevis* oocytes is initiated at the surface level of these germ cells. The effects differ in many important respects from what has been described in steroid hormone target tissues, and they can be mimicked or inhibited by agents which operate at the membrane level and/or induce changes of intracellular Ca^{2+} distribution.

Fully grown *Xenopus laevis* oocytes are arrested at the prophase of the first meiotic division; at this stage 'VI' (ref. 1), they have a diameter of about 1.2 mm, vitellogenesis is completed and the large nucleus (500 μ m) contains replicated DNA. They can be obtained free of follicle cells by appropriate collagenase treatment and can be cultured at room temperature. Progesterone (P) added to the medium induces 'meiotic maturation' *in vitro*²⁻⁴, which proceeds to the metaphase of the second meiotic division. The effects produced by the steroid include the breakdown of the nucleus or germinal vesicle (Gvbd), chromosome condensation, spindle formation and cytokinesis, with the production of an egg ready to be fertilised and the ejection of a small polar body. These events are associated with an increase of proteins related to meiosis, and eventually fertilisation and early embryonic development⁵⁻⁹; protein synthesis seems to be independent of transcriptional control throughout meiosis⁵⁻¹⁰. The eggs obtained *in vitro* are indistinguishable from those produced *in vivo* after gonadotropin stimulation of follicle cells where progesterone is released for direct delivery to the oocyte (without passing through the blood)¹¹; they are able to support cleavage and development after receiving a transplanted blastula nucleus¹².

With progesterone in the medium at 1 μ M concentration, Gvbd occurs *in vitro* after 5-8 h and is easily identified by the white spot observed on the pigmented animal pole of oocytes. During this period, the cytoplasm acquires a 'maturation promoting factor' (Mpf)^{4,13,14}, which can directly induce Gvbd when injected into an untreated oocyte. These results suggest the following sequence:

Mpf is neither progesterone nor a metabolite of progesterone. Indeed, progesterone does not provoke Gvbd when injected directly into the oocyte. It does not act through a nuclear mechanism, and can induce Mpf in enucleated oocytes and in actinomycin D or ethidium bromide treated oocytes. In cells exposed to cycloheximide, the hormone is ineffective; however, Mpf injected into such oocytes produces its normal effect^{12,15}.

We are concerned here with the mechanisms by which progesterone triggers the formation of Mpf, proteins and eventually Gvbd in the incubated oocytes.

Progesterone concentrations required

When oocytes are exposed to different concentrations of progesterone for 8 h, a dose-effect relationship is observed using Gvbd as response (Fig. 1). The half-maximum effective concentration (ED_{50}) is of the order of 10-100 nM. The dose-response curve depends on the time of progesterone exposure: if one observes Gvbd after a much longer time (24 h), lower concentrations of progesterone are found to be active. The 'real' apparent interaction constant of the hormone with the oocyte is difficult to calculate because Gvbd is a late event far removed from progesterone interaction with the oocyte, and as, according to the hormonal state of the female, oocytes are ready to 'mature' more or less rapidly, then each experiment must have its internal control.

It has been reported that the degree of progesterone stimulation of maturation is not dependent on its molar concentration, but rather on the actual quantity of hormone available, and the

Fig. 1 Progesterone and ACA-poly (EO) activation of meiotic maturation expressed as the % of oocytes undergoing Gvbd. At each experimental point, 100 oocytes were incubated continuously with the inducer (concentrations in incubation medium at zero time), and the % of Gvbd was scored after 16 h exposure. Each point represents the mean of six different experiments on different females. ED_{50} for ACA-poly (EO) (□) and for progesterone (○) were, respectively, 30 and 2 μ M. 0.1 mM O_2 -poly (EO) (★) did not induce maturation.

incubation medium volume for a given concentration¹⁶. However, when enough time is allowed for observing completion of the maturation, the same efficiency is obtained whatever initial volume is used (Fig. 2). Moreover, incubation of oocytes with a polymer-bound steroid (Fig. 3 and below) does not display the apparent volume dependence of progesterone for short incubation periods (Fig. 2); the explanation for this difference may be that the polymer-bound steroid, in contrast to progesterone, cannot enter the cell and subsequently does not undergo trapping and/or transformation to inactive metabolites or metabolites less active than the parent compound.

Steroid specificity of agonists

Many steroids other than progesterone are very active (Table 1). The hormonal specificity is very different from that observed in progesterone-sensitive somatic cells. (This is based on observations in mammalian and avian progesterone target tissues, as we are not aware of similar studies in amphibians.) Thus, testosterone, deoxycorticosterone (acetate) and cortisol are very active. Certain 5 α and 5 β -reduced metabolites of progesterone and testosterone are also active, even though they cannot be metabolised back to the parent hormone. Pre-hormones, which may be transformed into active hormones, are also agonists. However, it must be emphasised that not all steroids are active. Oestradiol is not an agonist, and, as seen on Table 1, only some

of the other oestrene derivatives of the 19-nor-testosterone series are active, and the chemical substitutions which influence activity do not lead to gross differences of charge and solubility. Large nonpolar compounds such as cholesterol and cholestenone, as well as deoxycholic acid, are inactive.

Accordingly, the stereochemical diversity of steroids active in oocytes is impossible to reconcile with the high specificity of steroid hormone-receptor interactions in somatic cells¹⁷. Moreover, the apparent ED_{50} s for the most active steroids are of the order of 10 nM–1 μ M, somewhat higher than the active concentrations of 'free' (non-protein-bound) steroid hormones in the plasma of mammals and also higher than the equilibrium binding constant K_d of steroids with classical proteinic receptors.

No saturation has been observed when studying the physical interaction of active (progesterone) or inactive (oestradiol) steroids with oocytes. This may be related to their large uptake and nonspecific retention by the yolk. These complications account for the absence of publications of competitive binding experiments, whether with agonists or antagonists.

Fig. 3 Proposed structure of the steroid derivatives. $X = -NH-(CH_2)_3-NH-(CH_2-CH_2-O)_n-CH_2-NH-(CH_2)_3-NH-$; ACA = androsta-4-ene-3-one-17- β -carboxylic acid; EO = amino-propyl-polyethylene-oxide. Note that in the case of E_2 -poly(EO), the MW of poly(EO) is 6,000, whereas for ACA-poly(EO), the MW of poly(EO) is 20,000 (see ref. 23).

Despite these difficulties, it has been possible to show that some synthetic steroids which are inactive or weak inducers of meiosis even at very high concentrations, can act as antagonists of progesterone action. Data concerning R-2341, a potent androgen in mammalian tissues, are reported in Fig. 4, and effects of other steroids are shown in Fig. 5. It is also remarkable that we have observed inhibition of progesterone action with oestradiol and other oestrenosteroids (Table 1), but not with diethylstilboestrol, a nonsteroidal oestrogen. Together with the fact that cholane and cholestane derivatives are neither active nor antagonistic, the results give evidence for some type of specific binding site for progesterone action in oocytes which differs profoundly from that known in classical progesterone target tissues.

Site of progesterone action

From the lack of Gvbd after progesterone injection into oocytes, it has already been suggested that progesterone may interact with the surface membrane to exert its effects (refs 13, 18), and no specific binding of progesterone has been found in soluble extract from oocytes. However, microinjected cortisol induces maturation, perhaps due to different physicochemical properties¹⁹. The argument based on the nonactivity of injected hormone for designating the membrane as the site of action is not very strong, as injected Ca^{2+} does not give Gvbd, whereas calcium introduced into the cell by iontophoresis is active.

Fig. 2 Time-dependent induction of maturation in the presence of different initial doses of progesterone or polymer-bound steroid, as expressed as Gvbd. 100 oocytes were incubated in 1 (---) or 10 (—) ml of Barth medium in the presence of ▲, 1 μ M progesterone; □, 0.1 mM progesterone; ●, 0.1 mM polymer-bound steroid (see Fig. 3).

Table 1 Steroids reinitiating meiosis in *Xenopus laevis* oocytes in vitro

Agonists	
Progesterone	The most active natural hormone.
17,21-dimethyl-19-nor-pregna-4,9-diene-3,20-dione (R-5020)	A synthetic progestagen highly active in mammals.
Deoxycorticosterone (and acetate), cortisol, testosterone	Hormones nonphysiologically related to maturation.
Δ^3 -pregnenolone, Δ^4 -androstenedione, dehydroepiandrosterone	Prehormones, metabolisable to progesterone or testosterone.
5 α -, 5 β -dihydroprogesterone, pregnandiol, 3 α -hydroxy-5 α -pregnane-11,20-dione* 5 α -, 5 β -dihydrotestosterone, 5 α -androstan-3 α ,17 β -diol	Metabolites of progesterone or testosterone, not metabolisable back to hormones.
Cyproterone	Progesterone derivative, anti-androgen in mammals.
19-nortestosterone†(17 β -hydroxy-oestra-4-ene-3-one)	A synthetic androgen
Non (or weakly) agonists, but antagonists	
16 α -methyl- or ethyl or ethynyl-17 β -hydroxy-oestra-4-ene-3-one, 17 β -hydroxy-oestra-4,9,11-triene-3-one†(R-2341)	Synthetic derivatives of the 19-nortestosterone series.
Oestradiol, 17 α -ethynyl-oestradiol, estradiol-17 β -valerianate, 8-iso-oestradiol	Natural and synthetic oestrogens
Neither agonists nor antagonists	
13 β -propyl-cortisol, 13 β -ethyl-oestra-4,9-diene-3,17-dione, 17 β -hydroxy-13 β -ethyl-oestra-4,9,11-triene-3-one-17 α -ethynyl (R-2323)	Synthetic derivatives with a 2C or 3C-13 β side-chain (anti-progesterone in mammals).
Diethylstilboestrol	Synthetic nonsteroidal oestrogen.
Cholesterol, cholesta-4-ene-3-one, deoxycholic acid	C27 and C25 compounds.

* Used as an anaesthetic.

† Activities also described in ref. 65.

Melanosomes, however, have been shown to display a selective affinity for active steroids²⁰. This observation is difficult to interpret and cannot be considered to be due to melanin²¹, as oocytes of albino mutants also respond to progesterone.

Our experiments^{22,23} support the hypothesis that the decisive site of progesterone-oocyte interaction is at the surface level. Thus, it has been shown that a progesterone analogue, when linked to a macromolecule, is able to promote maturation without significant entry into the cell. The free steroid (androsta-4-ene-3-one-17 β -carboxylic acid, ACA in Fig. 3) is approximately as active as progesterone on oocytes. When it was linked to a soluble polymer (aminopropylamino-poly(ethylene oxide) poly (EO) of MW 20,000) the complex was found to provoke meiotic maturation with an ED₅₀ of approximately 3 μ M in 16-h incubation experiments (Fig. 1). All effects obtained with progesterone on protein synthesis and Mpf formation were also observed with the steroid-polymer.

Fig. 4 R-2341 inhibition of the progesterone-dependent release of meiosis in the oocytes of *Xenopus laevis*. The data represent the % of Gvbd of 100 oocytes incubated at room temperature in 10 ml Barth medium (pH 7.4). The oocytes are all taken from the same female for each type of experiment (a, b). Maturation was scored after 30 h continuous exposure to progesterone. R-2341 was added to the oocytes 16 h before progesterone. a, Frequency of oocyte maturation induced by 50 nM progesterone as a function of R-2341 concentration. b, Effects of progesterone on the frequency of oocyte maturation in the absence (■) or presence (●) of 2.5 μ M R-2341.

Fig. 5 Inhibition by different steroids of the progesterone-dependent release of meiosis in the oocytes of *Xenopus laevis*. The data represent the % of Gvbd, of 100 oocytes incubated at room temperature in 10 ml Barth medium (pH 7.4) plotted as a function of time after exposure to progesterone 1 μ M (○). The oocytes were all taken from the same female and preincubated for 16 h with: ethinyloestradiol, 10 μ g ml⁻¹ (□); 16 α -methyl-19-nortestosterone, 10 μ g ml⁻¹ (▲); 16 α -ethynyl-19-nortestosterone, 10 μ g ml⁻¹ (●); R-2341, 10 μ g ml⁻¹ (★).

Oestradiol attached to the polymer (up to 1 mM) and the polymer itself did not provoke Gvbd, confirming the specificity of action of the progesterone macromolecular analogue. The possibility of cleavage of the macromolecular derivative with release of active steroids during the incubation was ruled out using radioactive derivatives. These studies showed negligible uptake of the labelled macromolecular progesterone analogue compared to that of free steroids and there was no correlation between uptake and effect on Gvbd. Injection of the polymer-linked progesterone into the oocytes did not induce maturation. Finally, we found that the efficiency of the macromolecular steroid is linearly correlated with the time of actual exposure, in contrast to the curve obtained with progesterone (Fig. 6); this may be due to the hydrosolubility of the derivative, which is easily washed from the surface, contrary to hydrophobic progesterone, which is largely trapped by the oocyte. Concurrent with our studies, induction of meiosis was observed with deoxycorticosterone hemisuccinate coupled to aminoethylated agarose beads²⁴.

These results suggest that the steroid acts at the surface of the oocyte to initiate the meiotic maturation response.

Other inducers at the membrane level

A wide variety of nonhormonal compounds (Table 2), although active at the surface of cells, also trigger meiosis. Among these are several amphiphilic cationic drugs known to penetrate membrane phospholipids and increase the surface pressure.

The best representatives of such compounds are the β -adrenergic antagonists (for example, propranolol). Used in the millimolar concentration range (interaction of propranolol with β -adrenergic receptor has a K_D of approximately 1 nM), they display the so-called 'membrane stabilising effect' or 'local

anaesthetic activity' independently of their stereochemical configuration. It is possible that these effects are related to interaction with membrane phospholipid turnover²⁵⁻²⁹. In contrast, β -adrenergic antagonists lacking the hydrophobicity of propranolol, such as atenolol, practolol and sotalol, are not able to induce meiosis. The two latter compounds have no effects on phospholipid metabolism in other systems^{26,28,29}. It has been suggested that propranolol interaction with phospholipid constituents of the membrane provokes displacement of loosely bound membrane calcium with concomitant changes in calcium pools within the cells²⁵. It is possible, however, that propranolol

* Data from the literature obtained in various conditions and with different approaches.

Fig. 6 Effects of progesterone and of polymer-bound progesterone on maturation (% Gvbd) as a function of the duration of hormone exposure. Batches of 100 oocytes from the same female were distributed in test tubes containing 1 ml of incubation medium. At zero time progesterone 0.1 mM ($\square$), progesterone 1 μ M ($\triangle$) or polymer-bound steroid 0.1 mM ($\bullet$) were added. At various incubation times (abscissa), hormones were extensively washed with Barth medium and further incubated. After 24 h Gvbd was scored.

and amphiphilic congeners may influence intracellular Ca^{2+} levels by an action on Ca-ATPase in the oocyte membrane as has been observed in blood red cells³⁰ and in sarcoplasmic reticulum^{31,32}.

Some local anaesthetics induce meiosis, but their activity is not related to their effectiveness as local anaesthetics; thus, benzocaine and procaine are ineffective. It seems likely that the local anaesthetics act by influencing membrane phospholipids, with concomitant Ca^{2+} displacement^{25,33}, as found for propranolol-like drugs. Procaine and benzocaine have a very limited ability to displace calcium in the microsomal system³⁴.

A variety of drugs active on the central nervous system, including neuroleptics (chlorpromazine), antidepressants (imipramine), anorectics (fenfluramine) and some barbiturates, also display maturational activity. Their effect can be attributed to an interaction with membrane phospholipids (and possibly calcium) rather than with stereoselective receptors³⁵⁻³⁷. Phen-tolamine, an α -adrenergic antagonist, is active on oocytes and also shows membrane effects involving lipid metabolism and Ca^{2+} fluxes³⁸. A wide variety of drugs inactive on oocytes (Table 2) do not exhibit membrane phospholipid or Ca^{2+} effects.

Some organo-mercurial compounds³⁹, such as *p*-chloro-mercuribenzoate, have also been shown to induce maturation, possibly through interaction with SH-groups of the membrane, as induction is inversely related to their ability to penetrate the cells.

Calcium and progesterone

The earliest changes following hormone or drug interaction with the oocyte membrane leading to meiosis are unknown. However, there is considerable evidence which suggests that membrane and/or internal calcium distribution is affected.

Among drugs interacting with Ca^{2+} fluxes and/or intracellular exchanges, methoxyverapamil and verapamil were found to be potent inducers of meiosis. Both are tertiary amines and may be regarded as cationic drugs which, as propranolol-type inducers, act by displacing membrane Ca^{2+} (ref. 35), or inhibiting a Ca^{2+} efflux pump in the membrane which maintains low levels of intracellular Ca^{2+} . Inhibition of such a pump would cause the cytoplasmic Ca^{2+} concentration to rise. The positive effect of quinidine, in contrast to those of ouabain and caffeine, is probably attributable to its capacity for displacing calcium from binding sites as in the microsomal fraction of skeletal muscle³⁴. The direct or indirect interaction with Ca^{2+} fluxes of the other drugs listed in the last section of Table 2 are either not selective enough to promote meiosis, or are secondary to other ion permeability changes.

Involvement of Ca^{2+} changes has been also suggested by the action of lanthanum, which induces Gvbd and correlated

phenomena⁴⁰. La^{3+} has a very high affinity for the Ca^{2+} binding sites of Ca^{2+} -dependent ATPases. Moreover, Gvbd can be provoked by using ionophore A 23187 (if Mg^{2+} or Ca^{2+} is present⁴¹) or specific Ca^{2+} iontophoresis⁴², whereas its induction by progesterone or ionophore is suppressed when intracellular free Ca^{2+} is chelated by EGTA injection⁴³.

Calcium has been proposed as the 'second messenger' of several mitotic factors, and implicated in various changes occurring during cell division. It could then well be involved in progesterone action on oocyte meiotic division. Moreover, calcium is known to inhibit adenylate cyclase activity and its binding to phosphodiesterase activator has been reported. Indeed, early steps of progesterone action may be compatible with either a decrease of cyclic AMP and/or a decrease in the phosphorylation of protein(s) involved in the arrest of meiosis. The former has been observed in *Rana* oocytes (as well, incidentally, as the diminution of cyclic-GMP) (refs 44, 45). (However, the pattern given by our measurements of cyclic AMP in progesterone exposed *Xenopus laevis* oocytes differs somewhat from what has been found in *Rana* (S.S.-S. *et al.*, in preparation).) The latter is suggested by the effect of the injection of purified catalytic subunit of protein kinase (from rabbit skeletal muscle) which inhibits the progesterone-induced maturation⁴⁶; the regulatory subunit or the heat-stable protein inhibitor of cyclic AMP-dependent protein kinase, injected in the absence of progesterone, induces meiotic cell division. We have found⁴⁷ that cholera toxin is a powerful inhibitor of progesterone action. Taken together, these striking results suggest a role(s) for a cyclic nucleotide(s) in the meiotic cell division, possibly dependent on Ca^{2+} changes and leading to an early modification of protein phosphorylation⁴⁸ (clearly distinguishable from the burst of soluble protein phosphorylation occurring later, just before Gvbd⁴⁹).

Three membrane features

The studies reported suggest that three major areas of progesterone action at the surface level of amphibian oocytes merit detailed investigations (Fig. 7). (1) The nature of the interaction site for progesterone and other active steroids seems to be neither a conventional receptor protein nor a 'simple' nonspecific lipidic array. (2) The nature of the calcium binding site and/or ionophoric element, connected in some manner with the putative hormone site, is unknown. (3) The membrane

Fig. 7 The three membrane features implicated in the very early steps of progesterone action are schematically represented, and also seen as pharmacological targets ($\oplus$): agonist, $\ominus$: antagonist). The progesterone site can accept competing antagonist steroids (Table 1). The membrane intrinsic components can be modified by propranolol-like drugs (and other compounds interacting with membrane) at millimolar concentration (Table 2). They activate the postulated calcium site. (The drawing arbitrarily indicates that drugs do interact with membrane elsewhere than in the progesterone site: this is, however, not excluded.) The release of calcium from its membrane site follows steroid agonist interaction in the progesterone site or drug effect on the membrane; it can possibly be provoked by La^{3+} ions

environment is probably of importance for the activity of these hormone and calcium sites. Then perturbation of membrane structure/fluidity will alter their functions. We suggest that the various drugs of the propranolol type modify the oocyte membrane and in turn membrane-bound calcium in the same way as progesterone does.

Conclusions

Xenopus laevis oocytes have long been known to provide a useful tool for investigating several aspects of gene expression⁵⁰. Now, in relation to progesterone-induced meiotic maturation, these cells may contribute to a better understanding of other important problems.

(1) Initiation of meiosis at membrane level. Steroids are active in the resumption of meiosis in all amphibians so far tested and in lower vertebrates such as fish. In starfish, 1-methyladenine is the 'hormone'⁵¹. In mammals⁵², it was shown that one cannot release the oocyte from the follicle without resuming meiosis, and it was hypothesised that either the granular cells produce an inhibitor or that meiosis takes place in association with ovulation, which disrupts cell-cell interaction. The fundamental question is whether the processes leading to meiosis are always initiated at the membrane level and are the same in widely different species, despite differences in the initial trigger.

(2) Mechanisms of hormone actions. The molecular aspects of progesterone-membrane interaction may provide an opportunity to study a new type of target site for steroid hormones in somatic cells. For example, the very early effects of oestrogen on membrane permeability in uterine cells⁵³ may be relevant to such sites. It has already been suggested that steroid hormones act in part at the surface of target cells, and specific interactions have been described^{54,55}. The selective effects of deoxycorticosterone on *Neurospora crassa* permeability to cations⁵⁶ and of progesterone on *Dictyostelium discoideum* development⁵⁷, the specificity of steroid structure in anaesthesia^{58,59} and the physi-

cal effects of steroids on membranes^{60,61} should be further studied. In many systems, steroids are cell division and/or differentiation promoting/regulating factors, but as yet no related mechanistic studies have been carried out. The oocyte-progesterone system may suggest the importance of the interaction between steroids and plasma membrane in this respect, and more work should establish whether some features proposed in 'cell surface modulation'⁶² are involved. This is not to deny that steroid-receptor complexes act in somatic cells at the nuclear locus and that the largest part of the hormonal response is due to this action in the nucleus. The present results with oocytes support the idea that hormone interaction at non-nuclear site(s) may well be complementary to action at the nuclear level in somatic cells and may even be essential for some aspects of hormone activity (cell division). This concept, that a hormone may act at multiple loci in the target cell, has been previously discussed^{63,64}.

Finally, the possible role of calcium ions as second messenger of a steroid signal-membrane interaction is worth testing in other steroid-sensitive systems.

(3) General aspects. In *Xenopus laevis* oocytes, progesterone induces a series of events which are themselves of basic biological importance. For example, the unknown mechanism by which selective protein synthesis is involved at the translational level during progesterone action is of great interest. Mpf, a protein synthesis-dependent product of progesterone action, is remarkable because it promotes all events following meiotic division and it is possible that a similar mitotic promoting factor is to be found in somatic cells undergoing cell division under hormone stimulation.

Xenopus oocytes are arrested cells which may yield much information about events generated at the surface level to biologists who care to expose them to progesterone.

Strainmeters with high sensitivity over long periods have enabled the detection and identification of slow earthquakes: seismic events which produce records similar to those from normal earthquakes except that the time scale for the rupture process is considerably longer. Slow earthquakes provide a mechanism for stress redistribution before normal earthquakes. Stress concentration may take place just hours or days before an earthquake; if it did, this would affect prediction capability.

EARTHQUAKES are generally assumed to result when the gradual stress buildup in a region eventually exceeds some critical local strength. The fracture which develops is thought to propagate at a velocity approaching that of shear waves. Although this is supported by laboratory experiments¹, there have always been observations which cannot be explained by fracture in an otherwise perfectly elastic medium. The time periods between events in a foreshock–aftershock sequence, for example, far exceed the time necessary for elastic redistribution of stress. Clearly, one or more other mechanisms must have a major role in the stress redistribution.

There have been various studies^{2–4} of particular earthquakes inferring coseismic processes with time scales longer than normally associated with earthquakes. However, the evidence for these so-called 'slow' or 'silent' earthquakes has generally been indirect (for example, anomalous long-period spectral behaviour³ or unusually long surface-wave coda⁴) as the time scale of such processes lies outside the passband of conventional seismographs.

A network of Sacks–Evertson borehole strainmeters⁵ was installed along the seismically active Pacific coast of Honshu south of Tokyo which enabled the investigation of the possibility of 'infraseismic' mechanisms for redistribution of stress. These instruments have high sensitivity from zero frequency to several Hz. In addition, tests with nearby explosions (producing accelerations up to g at the instrument) produced no spurious recordings⁵.

New, direct observations of strain redistribution interpreted in terms of events which we call slow earthquakes are reported here. All our observations are consistent with the hypothesis that these slow earthquakes are similar to normal earthquakes in

all respects except for slower rupture velocities and longer rise times. Here we describe slow earthquakes which occur separately from normal earthquakes and which were observed on the recently installed borehole strainmeters or on nearby extensometers. Other kinds of data are also included which indicate that the stress buildup before an earthquake may be non-linear in time. In these cases the concentrations of stress seem to occur in a much shorter time preceding the earthquake than that calculated on the basis of magnitude–precursor–time formulae⁶.

Strainmeter waveforms for normal and slow earthquakes

To understand the characteristics of slow earthquakes, we first examine strain waveforms from normal earthquakes, particularly in the near field (less than 10 fault lengths) where observations of slow earthquakes are most convincing. Figure 1 shows the radial strain field based on a modification of a dislocation model in the form presented by Harkrider⁷. The theory is oversimplified (for example, a point source in an infinite space is assumed) but the results are expected to be qualitatively correct.

The waveforms shown in Fig. 1 can be treated as the superimposition of two parts: a strain step which is proportional to the moment and which falls off as the cube of the epicentral distance, and a 'radiated' pulse which is defined here to include both a term with zero total area which falls off with distance as well as a term whose area is proportional to the moment but which falls off with the square of the distance. Within a few fault lengths (see Fig. 1a) the strain step dominates, while beyond about 20 fault lengths the step would not be detectable—except for an event with an extremely large fault offset.

Figure 2a is a wide-frequency-range borehole strainmeter record from Matsushiro of a nearby small ($m = 4$) earthquake. The compressional wave is followed by a larger shear arrival, and the static offset arrives shortly after S . The basic low-frequency structure is emphasized and the higher-frequency oscillations suppressed in the (effectively) low-pass filtered version of the same record shown in Fig. 2b; this and the record shown in Fig. 3a (a low-pass filtered record of the same earthquake from the Hokushin Observatory near Nagano) show good agreement with the theoretical strain record of Fig. 1c.

Figure 3b shows a strain event recorded by a borehole strainmeter at Irako. Although the record shown is from a

Fig. 1 Theoretical waveforms of radial strain plotted against time of an event at different epicentral distances. *a*, At close distances, there is a relatively slowly rising step. The duration is the time for which movement (rupture) occurs on the fault. *b* and *c*, at greater distances the radiated pulse is observed because it decays with distance less rapidly than does the strain step. The rise time is the time needed for the strain to achieve 86% of its peak value. The time scale is the same in all cases, and the amplitude scales with increasing distance as indicated.

wide-frequency-range channel such as that used for Fig. 2*a*, only low frequencies appear in the arrival. The waveform is similar to that of the earthquake in Fig. 3*a* and to the theoretical waveform in Fig. 1*c*. Many such events have been observed on the recently installed borehole strainmeters as well as on some nearby extensometers. The radiated pulses and strain steps from such events seem to be similar to those from normal earthquakes except that the rise time and duration are about 100 times longer than those for earthquakes of similar moment. It is therefore possible to produce slow-earthquake waveforms which are in reasonable agreement with observation by using normal-earthquake theory with long rise times and low rupture velocities.

Fig. 2 Record from the borehole strainmeter at MAT of an $m = 4.0$ earthquake on 19 September 1973 at a distance of 15 km. *a*, Broadband-response record. *b*, Low-pass filtered record from a different sensor in the same instrument. This sensor has a higher noise level. The magnification of the trace in (*a*) is about one-half that of the trace in (*b*). The traces are slightly offset in time for ease in viewing.

At smaller distances, the theory then predicts records such as shown in Fig. 1*a*. Figure 3*c* shows a slow earthquake with similar waveform. It should be kept in mind, however, that for observations on only a single instrument there is an unresolvable ambiguity between an event being near, slow and of a certain moment or further, slower and of a larger moment.

Events such as those in Fig. 3*b, c* differ from creep events (observed close to a long fault) in that in such events there is no permanent change in the strain field⁸.

The expanded time scale for slow earthquakes means that almost no energy is radiated in the normal seismic frequency band, so that slow earthquakes cannot be detected by seismometer networks used for earthquake location. Even with instruments of high magnification at low frequencies, only nearby events can be clearly identified because theoretical considerations suggest⁹ that the low rupture velocities for these events result in low radiation efficiencies. Hence, such instruments are required in denser networks than now exist to do multi-instrument correlations of individual slow earthquakes.

Fig. 3 *a*, Low-pass filtered strainmeter record from the same earthquake as in Fig. 2 recorded at Hokuahin, near Nagano (distance = 15 km, Hokuahin-MAT distance = 13 km). This record can be compared with the theoretical waveform in Fig. 1*c*. *b*, Slow earthquake record for 25 June 1976 from the broadband-response sensor of the borehole strainmeter installed at Irako, on the Pacific coast. Note the similarity between this record and that from a normal earthquake (above) as well as the theoretical waveform in Fig. 1*c*. *c*, Slow earthquake record on 26 July 1976 from Irako. This event is either of similar time scale but at a closer distance compared to the one above or it is slower and at a similar distance.

Foreshocks and aftershocks of slow earthquakes

Shallow earthquakes may have foreshocks and aftershocks which are considerably smaller than the main event. Slow earthquakes may exhibit similar behaviour; Fig. 4 shows a slow earthquake accompanied by a foreshock-aftershock sequence. Relative to the step size, the foreshocks have larger radiated pulses than the aftershocks. If these are all at more-or-less the same distance and have similar rise times, one interpretation is that the foreshocks have higher stress drops. Such a phenomenon has been claimed for some instances for normal earthquake foreshocks and aftershocks¹⁰.

Slow earthquakes as precursors for a normal earthquake

Figure 5 shows the relative locations of the borehole strainmeter at Shizuoka, the Fujigawa extensometers and the epicentre of an $m = 5.5$ earthquake which occurred on 15 June 1976. Also shown are the dates and (relative) amplitudes of strain steps associated with slow earthquakes observed at the two observatories. The Fujigawa extensometers have operated for several years, but slow earthquakes were recorded only during the period January-May 1976. The borehole strainmeter at Shizuoka began operation in early April 1976 and recorded slow

Fig. 4 Irako borehole strainmeter record for 25 August 1976. A slow earthquake, strain = 7×10^{-8} , is shown preceded by foreshocks and followed by aftershocks with strains less than 10^{-9} . Expanded-scale tracings of sample foreshocks and aftershocks are included. The strain record has been high-pass filtered at 25-min period.

earthquakes (of the opposite polarity from those at Fujigawa) from that time until early June. None of the events is recorded at both observatories. Based on the Fujigawa records, the slow earthquakes started about 150 d before the earthquake, which is an often quoted⁶ precursor time for an earthquake of that magnitude.

A model consistent with these observations has been suggested by Y. Okada (personal communication). The observatories are on opposite sides and within a few kilometres of the Fossa Magna, a major geological discontinuity (see Fig. 5). Okada notes that the relative amplitudes and polarities of the slow earthquakes at the two observatories could be explained if the slow earthquakes occurred on the Fossa Magna.

Other detections of preseismic stress redistribution

There are other data which indicate that the concentration of stress in an epicentral region may be very nonlinear in time: three examples are given here.

Figure 6 shows the tide-gauge record from Irozaki, on the tip of the Izu peninsula, Honshu, Japan for the day on which a nearby $m = 6.9$ earthquake occurred. In this region, the return time for such an earthquake is many decades. As can be seen in Fig. 6, there is a deviation from the expected tide level apparent about 20 min before the earthquake. This deviation is in the opposite sense to the eventual level change due to the earthquake. An interpretation could be that, due to a nearby slow earthquake shortly before the normal earthquake, there was a buildup of strain of about one-third of that eventually released.

Fig. 5 Time history of the slow earthquakes (recorded on the borehole strainmeter at Shizuoka and on the Fujigawa extensometers) preceding the $m = 5.5$ Yamanashi earthquake. The Shizuoka observatory began operation in April 1976. The amplitude scales for the two instruments are not the same, but the relative polarity of the strain steps is as indicated. Also included is a map showing the relative locations of the two observatories, the epicentre (C) and the Fossa Magna.

Rikitake¹¹ describes a number of tilt changes that have been reported preceding large earthquakes. While his examples establish that large changes of ground level or tilt occurred some days or hours before earthquakes, in most cases there are no instrumental observations which would allow quantitative estimates. One exception is the Tonankai earthquake ($m = 8$) of 7 December 1944.

Levelling surveys in the region of Kakegawa (~150 km north east of the eventual epicentre) showed slight subsidence corresponding to a tilt of 3×10^{-6} rad in the 10 yr preceding the earthquake. On the morning of the earthquake (which occurred at 13 36 LT) a level-survey team was operating north of Kakegawa. Over a 2-h period (up to 12 noon) closure errors of 9 mm over 2 km were found; during this brief period the ground had tilted 4.5×10^{-6} rad in the sense of uplift at Kakegawa. Comparison of a survey immediately after the earthquake with one completed a month before showed a tilt of about 10^{-5} rad in the region north of Kakegawa. This total tilt was in the same

Fig. 6 Tide-gauge record from the tip of the Izu peninsula for 9 May 1974. On this date an $m = 6.9$ earthquake occurred within a few kilometres of the tide gauge. Note that preseismic motion is apparent about 20 min before the earthquake.

sense as the rapid precursory tilt on the morning of the earthquake. Thus this precursory tilt and that due to the earthquake were approximately equal.

A possible interpretation is the precursory tilt was due to a slow earthquake of moment comparable to the normal earthquake.

An $m = 5.2$ earthquake near Hollister, California, on 28 November 1974 was preceded by tectonomagnetic effects¹² and anomalous tilting¹³. Magnetic field changes of about 1.5–2 nT measured at some 16 km from the eventual epicentre occurred over a period of about 2 weeks ending 4 weeks before the earthquake. The time periods involved were much less than the normally found precursory time for an $m = 5.2$ event, and at the distance of the observing stations, there is no anomaly coincident with the quake.

These observations could be explained by slow earthquakes redistributing the regional stress in a manner similar to that suggested by Smith and Johnston¹².

On 14 January 1978, there was an $m = 6.5$ earthquake at 23 km depth near O-Sima Island, Japan. The epicentre was ~33 km from the borehole strainmeter at Irozaki. From the time of its installation in April 1976 through November 1977 the observed strain rate was less than 10^{-7} per month. Six weeks before the earthquake, a compressional excursion of 2×10^{-6} occurred over a period of about 20 d. The strain remained relatively constant at this level until about 4 d before the earthquake, when a dilatational trend began. This provides another example of stress redistribution directly preceding an earthquake.

Conclusions

It is likely that strainmeters and tiltmeters, of adequate stability and sensitivity, installed in active tectonic regions would and

have recorded similar events to the slow earthquakes reported here¹⁴.

The simplest model of events leading to an earthquake is that stress builds up gradually in the eventual earthquake region due to some process such as plate motion. At some stage of stress—and in some areas only—dilatancy may occur. In principle, it is possible to detect this dilatancy through measurements of V_P/V_S , elevation changes and other associated phenomena.

We believe, however, that this is not necessarily the sequence for all large, shallow earthquakes. The available data suggest that while there may be a stress buildup in large regions due to tectonic processes, the stress may not become concentrated in the eventual earthquake region until shortly before the earthquake. One mechanism for this nonlinear in time stress concentration is the slow earthquake.

Two significant implications are: (1) if high stresses may not be concentrated in the source region until possibly a few days or less before even large earthquakes, this would set the effective upper limit to the warning period that a specific prediction could

provide for such events. (2) If there are great slow earthquakes, this would be important in the excitation of the Chandler wobble^{15,16}.

Aquatic sources and sinks for nitrous oxide

James W. Elkins, Steven C. Wofsy, Michael B. McElroy, Charles E. Kolb* & Warren A. Kaplan

Center for Earth and Planetary Physics, Harvard University, Cambridge, Massachusetts 02138 and *Center for Chemical and Environmental Physics, Aerodyne Research, Inc., Bedford, Massachusetts 01730

Oxidation of organic material seems to represent a source for N₂O in a wide variety of aquatic systems. Consumption of the gas, attributed to microbial respiration, is observed for a few specific anoxic environments.

NITROUS OXIDE plays an important part in stratospheric chemistry^{1–4} and may influence the radiative budget of the troposphere⁵. Concern has arisen recently^{6,7} that human activity could lead to a significant increase in the source strength for atmospheric N₂O. Assessment of this possibility is hampered by major gaps in our understanding of processes which regulate N₂O in the natural system.

The gas is thought to originate primarily as a product of microbial metabolism^{8,9}. Stratospheric photolysis can remove at most 10⁷ tons of nitrogen per yr and represents the only currently established atmospheric sink^{9,10}. The magnitude of the global source is uncertain, with particular controversy attached to the role of the ocean.

Hahn¹¹ (also Hahn and Junge¹²) concluded, from limited measurements of dissolved N₂O, that the ocean should represent a major source for atmospheric N₂O, contributing as much as 10 times the quantity of gas consumed in the stratosphere. McElroy *et al.*¹³ argued, from consideration of marine productivity, that the oceanic source should be small and raised the possibility that microbial respiration in conditions of low oxygen could offer an important sink for marine N₂O. They speculated that consumption of N₂O might exceed production on an integrated basis for the world's oceans.

This article summarises recent results which attest to the complexity of the aquatic nitrogen cycle as it affects N₂O. We present data from Central and South East Tropical Regions of the Pacific Ocean, and from Chesapeake Bay. Our results support the view^{11,14,15} that oxidation of ammonium and amino nitrogen, nitrification, should represent a major source for marine N₂O. They allow a quantitative estimate for the relevant source strength, implying a global yield for oceanic N₂O of less than about 10⁷ tons N yr⁻¹. Data from the South-east Tropical Pacific and from Chesapeake Bay demonstrate consumption of dissolved N₂O in conditions of low oxygen, as observed by others^{15,16}. There is no evidence to date, however, for consumption of atmospheric N₂O by the open ocean. We report preli-

minary observations indicating consumption of atmospheric N₂O by a number of aquatic systems, including a freshwater pond and a tidal saltmarsh.

Central Pacific

The data discussed here were collected between 2 and 18 December 1977 on the Norpax Leg II cruise of the RV Kana Keoki. Samples were taken to depths of 1,000 m every degree of latitude along the 150° W meridian, between 17° S and 20° N, and were analysed for temperature, salinity, O₂, N₂O, NO₂⁻, NO₃⁻, NH₄⁺, PO₄³⁻ and SiO₂. Analytical techniques are discussed elsewhere^{17,18}.

Cross sectional contours for N₂O, PO₄³⁻ and NO₃⁻ exhibit several similar structures (Fig. 1). Highest concentrations of N₂O are observed at 9° N at a depth of 129 m in an intense feature associated most probably with upwelling in the north tropical divergence zone¹⁹. This feature may be seen also in the contours for PO₄³⁻ and NO₃⁻. Highs in N₂O at 17° N (128 m) and 4° S (502 m) are similarly correlated with structure in PO₄³⁻ and NO₃⁻.

Concentrations of N₂O in surface waters are generally close to equilibrium with the atmosphere. Largest surface concentrations are observed in the zone of high productivity associated with the equatorial upwelling, where N₂O is supersaturated with respect to air by a factor of ~1.4.

On average, surface waters are supersaturated with respect to the atmosphere by a factor of ~1.25 (±0.1), equivalent to an excess of N₂O equal to 38 ± 10 ng N l⁻¹. The uncertainty in this quantity reflects imprecision in the available solubility data, errors associated with the application of these data to seawater, and inevitable uncertainties introduced by subtraction of nearly equal experimental quantities.

Highest concentrations of N₂O in Fig. 1 correspond to regions of low oxygen. It is of interest to consider the relationship between ΔN₂O and ΔO₂, where ΔX defines the excess of X with respect to the atmosphere at the local water temperature and salinity. The quantity ΔN₂O provides a measure of the net accumulation of N₂O in a water mass since its last contact with the air. By the same token -ΔO₂ provides a cumulative record of the net quantity of oxygen consumed over the same period due to oxidation of organic material.

Fig. 1 Cross sections for *a*, N_2O ($\mu\text{g l}^{-1}$); *b*, NO_3^- and *c*, PO_4^{3-} ($\mu\text{g-atm l}^{-1}$) along the 150°W meridian in the tropical Central Pacific Ocean. Experimental precision is better than 3% for N_2O and $0.1 \mu\text{g-atm l}^{-1}$ for NO_3^- and PO_4^{3-} .

Figure 2a shows a plot of $\Delta\text{N}_2\text{O}$ against $-\Delta\text{O}_2$ (the apparent oxygen utilisation or AOU). We include here all of the data in Fig. 1, except for results from active regions at 17°N and $8-13^\circ\text{N}$ (above 200 m) and from 2 to 4°S (above 500 m). The results indicate (see also ref. 14) that a linear relationship may exist between $\Delta\text{N}_2\text{O}$ and $-\Delta\text{O}_2$, and that this relationship may hold over extensive regions of the world's oceans. Indeed data from active zones may also exhibit linear dependence of $\Delta\text{N}_2\text{O}$ on $-\Delta\text{O}_2$ (Fig. 2b). The value for $\Delta\text{N}_2\text{O}$ is, however, larger in this case for any particular choice of $-\Delta\text{O}_2$.

The linear behaviour exemplified by Fig. 2 suggests that production of N_2O , at least for portions of the ocean below the mixed layer, may occur primarily as a byproduct of the oxidation of organic material¹⁴. Production of N_2O during nitrification, observed in culture for both soil²⁰ (*Nitrosomonas europaea*) and marine (*Nitrosococcus oceanus*) organisms (unpublished data from this laboratory) offers a plausible explanation. If we assume that the C:N:P ratios in marine organic material are similar to values quoted by Redfield *et al.*²¹, 106:16:1, and assume further that the stoichiometry of decay may be represented by

then the data in Fig. 2 may be used to estimate the corresponding yield for N_2O . The behaviour exhibited in Fig. 2a suggests that 1 molecule of N_2O may be formed on average for every 4,700 carbon atoms which undergo oxidation.

The difference in slopes exhibited by the data in Fig. 2a and b might be attributed to various factors—differences in the C:N:P ratios of organic material; intrinsic differences in the yield for production of N_2O ; *in situ* production and loss of O_2 due to photosynthesis and respiration; complications due to admixture of different water masses; and additional sources of N_2O in active regions associated either with denitrification or with assimilatory reduction of nitrate. It seems that $\Delta\text{N}_2\text{O}$ may be an increasing function of temperature at given AOU. The relation

$$\Delta\text{N}_2\text{O} = -0.46 + \{0.180 + 0.027T\} \text{ AOU}, 25 > T > 5^\circ\text{C}$$

with $\Delta\text{N}_2\text{O}$ and AOU measured in units of $\mu\text{g l}^{-1}$ and ml l^{-1} respectively and with T in $^\circ\text{C}$, provides an excellent fit to all of the data except results from the active region between 8 and 11°N . The root mean square deviation of the data from values

predicted on the basis of the above relation is only $0.3 \mu\text{g l}^{-1}$ for 238 observations characterised by an average value of $\Delta\text{N}_2\text{O}$ equal to $1.4 \mu\text{g l}^{-1}$. The higher yield for production of N_2O at elevated temperature is consistent with temperature sensitivities observed in the laboratory by Yoshida and Alexander²⁰.

Fig. 2 N_2O observations (Fig. 1) expressed as excess N_2O plotted against apparent oxygen utilisation. Most of the data are shown in (a) but data from the active regions at 17° , $13-8^\circ\text{N}$, and $2-4^\circ\text{S}$ are plotted separately in (b). The straight lines are least-squares fits, which yield r.m.s. deviations of 0.37 and $0.6 \mu\text{g l}^{-1}$ for (a) and (b) respectively. Data points from the mixed layer ($\text{AOU} < 0.3 \text{ ml l}^{-1}$) are not included. The measured concentration of atmospheric N_2O was 291 parts per 10^9 (by volume) (p.p.b.).

Peruvian upwelling

An extensive series of measurements was carried out off the coast of Peru from the RV Knorr between 20 and 31 March 1978. A representative depth profile, including data for temperature, N_2O , O_2 , NO_2^- , NO_3^- and NH_4^+ , is given in Fig. 3. For comparison, concentrations of N_2O expected on the basis of the temperature dependent formula quoted above are shown.

The empirical relation provides excellent agreement with N_2O measurements below 300 m and is in accord also with observations at 30 and 50 m. A major discrepancy exists between 100 and 300 m. Comparison of observed and calculated profiles suggests that consumption of N_2O may be important in this zone. Indeed the observed concentration of N_2O is undersaturated with respect to the atmosphere between 150 and 250 m, a region in which oxygen concentrations lie below 0.1 ml l^{-1} .

The zone of low O_2 and N_2O includes a maximum in the concentration of NO_2^- , a feature attributed by others^{15,22} to reduction of NO_3^- . The minimum in N_2O almost certainly reflects respiration of the gas at low concentrations of O_2 as suggested by McElroy *et al.*¹³ and by Cohen¹⁶. It is consistent with a model²² which invokes a major role for denitrifying bacteria at concentrations of oxygen below 0.1 ml l^{-1} .

Further support for the role of denitrifying bacteria may be inferred from incubation experiments carried out as part of the present sequence of observations. Most samples for N_2O analysis were killed immediately with $HgCl_2$. A number of samples, however, were incubated live, in 60 ml BOD bottles. Some of these samples were treated with trace concentrations of C_2H_2 , a procedure known²³ to inhibit reduction of N_2O by denitrifiers. Samples of water from regions of low O_2 , treated with C_2H_2 , showed generally high concentrations of N_2O following 18-day incubation intervals. In one case a sample, with an initial concentration of N_2O equal to $1.3\text{ }\mu\text{g l}^{-1}$, developed a concentration of N_2O of $4.3\text{ }\mu\text{g l}^{-1}$ within an hour of application of C_2H_2 . The concentration of N_2O had reached $191\text{ }\mu\text{g l}^{-1}$ after 18 days, indicating accumulation of N as N_2O in an amount equivalent to ~30% of the starting concentration of NO_3^- . Results from eight other C_2H_2 treated incubation experiments showed 18-day N_2O concentrations in the range 3.3 to $47.0\text{ }\mu\text{g l}^{-1}$. Net consumption of N_2O was exhibited by all samples incubated without C_2H_2 .

Other systems

Figure 4 summarises N_2O observations taken in Chesapeake Bay during July 1977. The data were acquired in waters with total depths in excess of 13 m, and show clear evidence for consumption of N_2O below the seasonal thermocline.

There appears to be an abrupt change in the behaviour of N_2O when the concentration of O_2 falls below 1.4 ml l^{-1} . Waters are then undersaturated in N_2O with respect to air. Indeed at several stations, concentrations of both O_2 and N_2O were observed to lie below present detection limits of 0.1 ml l^{-1} and $0.02\text{ }\mu\text{g l}^{-1}$ respectively.

Fig. 3 Depth profiles for N_2O , mineral nitrogen, oxygen and temperature for a station at $15^{\circ}10.6'S$, $75^{\circ}35.5'W$, in the region of Peruvian upwelling. The dashed line represents the relationship $\Delta N_2O = -0.46 + 0.180 + 0.027 T\text{ AOU}$.

Fig. 4 N_2O and O_2 data for Chesapeake Bay. The % saturation of N_2O is given relative to the observed atmospheric concentration of 291 p.p.b., for $T \approx 27^{\circ}C$.

Depth profiles for N_2O , O_2 , temperature, salinity and mineral nitrogen are shown for two stations in Fig. 5. Station A, included in Fig. 4, illustrates the rapid decrease with depth below the thermocline observed for both N_2O and O_2 . Note that NH_4^+ is the dominant form of mineral nitrogen at all depths in these waters. Station B, occupied following a period of cool windy weather, shows evidence for transient breakdown of the thermocline, with associated mixing of deep and shallow waters. Note in this case that surface waters seem to be undersaturated in N_2O with respect to the atmosphere, suggesting that in summer the Chesapeake may represent at least a transient sink for atmospheric N_2O following periods of rapid vertical mixing. A more extensive sink may occur in anoxic muds associated with tidal saltmarshes as indicated by preliminary studies of a marsh on the margin of the bay at the Choptank River. Waters draining this marsh at low tide were undersaturated in N_2O by 30% with respect to air.

Fig. 5 Depth profiles for N_2O , O_2 , T and S in Chesapeake Bay for station (a), occupied 14 July 1977, and nearby station (b), occupied 27 July 1977. Weather was generally warm and stable, except for a cool windy period 25–26 July. Note undersaturation of N_2O in surface water and nearly isothermal structure at station (b). Location of (a) is $38^{\circ}50'05''N$; $76^{\circ}23'53''W$; location (b), $38^{\circ}40'15''N$; $76^{\circ}25'00''W$.

Consumption of N_2O seems to arise for at least one other system at oxygen concentrations below 1.4 ml l^{-1} . Figure 6a shows a summary of results obtained in a diurnal study of a shallow pond (denoted pond A) in Concord, Massachusetts, a system reported elsewhere¹⁷ to represent a sink for atmospheric N_2O . The present study confirmed that this pond was undersaturated in N_2O over a complete diurnal cycle. Concentrations of O_2 are relatively high during the day, reflecting a strong photosynthetic source. Concentrations of N_2O increase with time when O_2 concentrations are above 1.4 ml l^{-1} , reflecting, presumably, infusion of gas from the air. Figure 6 gives clear evidence for consumption of N_2O at oxygen levels below 1.4 ml l^{-1} . In contrast to pond A, the adjacent pond B remains well oxygenated through the night. It functions as a source of atmospheric N_2O and exhibits a relationship between N_2O and O_2 similar to that observed in the Central Pacific (see Fig. 6b).

It is probable that the sinks observed for N_2O in both the Chesapeake bottom water and in the pond discussed above, reflect utilisation of the gas as an electron acceptor by micro-organisms functioning at low levels of oxygen. Alternate elec-

tron acceptors, such as NO_3^- and NO_2^- , are present in relatively low concentration in these systems, in contrast to the Peruvian upwelling regions where NO_3^- and NO_2^- are relatively abundant. It would be tempting to attribute consumption of N_2O in all these systems to denitrifying bacteria. The hypothesis that denitrifying bacteria may effect removal of N_2O is supported for Peru by the inhibition experiments described earlier. Further work is necessary to clarify the nature of the sinks operative in the pond and bay.

Conclusions

Data from the Central Pacific, Peru, Chesapeake Bay and various ponds and rivers demonstrate that aquatic systems contain both sources and sinks for N_2O . Nitrification may represent a dominant source for N_2O in both freshwater and saltwater systems. Observations from the Pacific, elaborated above, and from various rivers and ponds^{17,18} (see also Fig. 6b) support this conclusion. Present observations suggest that approximately 1 mol of N_2O is formed for every 700 mol of NH_4^+ which undergo oxidation.

A similar yield was observed in the laboratory for soils at comparable pH by Bremner and Blackmer²⁴, suggesting that this yield may have wide application. Indeed nitrification could represent a dominant global source for atmospheric N_2O .

The marine contribution to atmospheric N_2O should not exceed $10^7 \text{ tons N yr}^{-1}$. This follows from the assumption of a C:N ratio equal to 6.6 for the marine biosphere²¹. It applies if the rate for marine fixation of carbon^{25,26} is $2 \times 10^{10} \text{ tons C yr}^{-1}$ and if one can ignore assimilation of reduced forms of N by phytoplankton. A source of $\sim 10^7 \text{ tons N yr}^{-1}$ is consistent with most of the available marine data and is in accord with the Pacific surface measurements discussed here.

As discussed by McElroy *et al.*¹³, it is difficult to derive a reliable value for the global source strength of N_2O based on limited data from surface ocean waters. However, applying the conventional procedure^{11,12} to our data for the surface waters of the Central Pacific gives an estimate of a marine source for atmospheric N_2O of $7 \times 10^6 \text{ tons N yr}^{-1}$ between latitudes $\pm 20^\circ$. To make this estimate one must assume negligible time variability in the concentration of dissolved N_2O in surface water, zonal uniformity in the excess of its concentration with respect to the atmosphere, and a constant piston velocity. From our own data (Figs 1 and 3) it seems unlikely that these assumptions apply to the world oceans, although the resulting estimate is coincidentally close to the upper limit provided by the oxidation model. The multiple equilibration procedure used here provides from each analysis a measure for the solubility of N_2O in seawater. Our data suggest a solubility perhaps 10% larger at 25°C than that deduced from ref. 27 and would imply therefore that the source estimated from the thin-film model should be reduced by 30%. Note that the final concentrations of dissolved N_2O deduced from our analyses are independent of the solubility coefficient for the gas.

Microbial respiration in conditions of low oxygen can represent a sink for atmospheric N_2O . The importance of the process on a global scale is not clear. It has been demonstrated here only for relatively small scale environments. Results from the Chesapeake marsh are intriguing, however, in that coastal marshes and wetlands occupy significant areas of the globe, about $2 \times 10^6 \text{ km}^2$, comparable to areas occupied by regions of intensive coastal upwelling. Further studies are obviously required to quantify the part which biological uptake may play in the global budget of N_2O .

We acknowledge the hospitality of Norpax (North Pacific Experiment) and we thank K. Wyrtek, B. Patzert, T. Clarke, E. D. Stroup, S. Watson and G. A. Berberian for their contributions. We are indebted to J. Ledwell, L. Hashimoto and A. P. Durán for useful discussions. This work was supported by the US NSF and NASA under grant ENV76-24239 and contracts NASW-2952 and NSG 2031 respectively to Harvard University.

Fig. 6 a, Time rate of change for the concentration of N_2O in Concord pond A, shown as a function of dissolved oxygen. The pond is about 0.4 m deep and is stagnant, with no surface outlet. The water contained abundant flora but had negligible mineral nitrogen and was undersaturated in oxygen and nitrous oxide throughout the experimental period. b, Variations of N_2O and O_2 for Concord pond B. Quantities plotted represent differences between concentrations measured during the night, and concentrations measured at sunset, a procedure adopted to avoid confusion due to photosynthetic production of oxygen. Pond B contained appreciable dissolved NO_3^- ($\sim 10 \mu\text{g-atm l}^{-1}$). It is located adjacent to pond A and has a surface inlet and a surface outlet, with a water retention time of ~ 3 days. N_2O was supersaturated with respect to the atmosphere at all times, while concentrations of O_2 ranged between 3 and 7 ml l^{-1} . The best-fit linear relation between N_2O and O_2 is given by $\Delta N_2O = -0.235 (\pm 0.16) - \Delta O_2 \times 0.32 (\pm 0.06)$, close to the average line for all data from the Central Pacific.

Nautiloid growth rhythms and dynamical evolution of the Earth–Moon system

Peter G. K. Kahn*

Department of Geological and Geophysical Sciences, Princeton University, Princeton, New Jersey 08540

Stephen M. Pompea

Department of Physics, Colorado State University, Fort Collins, Colorado 80523

Daily growth lines and lunar monthly septa are formed in Nautilus pompilius Linnaeus shells. The number of days per lunar month determined using fossil shells has increased dramatically during the last 420 Myr, indicating that during this period the Moon revolved more rapidly and was much closer to the Earth than has previously been expected.

THE hypothesis that the Moon and Earth have been closer in Phanerozoic times has received considerable support from studies of the growth cycles of corals^{1,2}, bivalves^{3–8}, brachiopods⁹ and stromatolites^{10,11}, as well as from astronomical studies of tidal friction^{12–14}. These studies yield information about the rotation rate of the Earth, or the number of days per year, which is consistent with a closer and faster revolving Moon in earlier times. Tidal friction, by which bulges raised in the oceans by the Moon exert a torque on the Moon, implies the gradual expansion of the lunar orbit as well as an increase in the length of day with time. Both of these predictions have been confirmed for recent years by occultation measurements¹⁵, and for historical times by studies of ancient eclipses¹⁶. Unfortunately, the past dynamics of the Earth–Moon system cannot be derived solely from theoretical calculations based on recent and historical astronomical observations since tidal friction is critically dependent on sea level and continental configurations, both of which have changed markedly in the geologic past. Since an accurate charting of lunar orbital evolution has profound implications on lunar origin theories and on cosmological theories¹⁷ which predict lunar orbital expansion as a consequence of a varying gravitational constant, another approach is needed.

One viable approach to prehistoric lunar dynamics is through palaeobiology¹⁸. Nautiloids are organisms which possess a long evolutionary history (~500 Myr), but until now, they have not been investigated as possible geochronometers. We shall examine the hypothesis that there are daily and lunar monthly growth records preserved in the shells of *Nautilus*, and also in the fossil nautiloid shells beginning in the Ordovician, and discuss the implications for the evolution of the Earth–Moon

system. This synthesis suggests that the rate of lunar orbital evolution has been much greater in the past 420 Myr than short-term astronomical studies and theoretical calculations indicate.

Growth of *Nautilus*

Although nautiloid fossils are found throughout the world, the chambered *Nautilus* survives in the southwestern Pacific Ocean as the only genus of externally shelled cephalopods. Observations of *Nautilus in situ* are limited because of its nocturnal habits and its habitat—depths of up to 400 m and away from land masses. Observations on juvenile *Nautilus* are extremely limited²⁰. Thus, our study of *Nautilus* growth relies primarily on a study of shell macro and micro-structure, rather than on observations of the living *Nautilus* in its natural surroundings.

As *Nautilus* grows, convolutedly coiling its shell in the shape of a logarithmic spiral (Fig. 1), it incorporates two kinds of rhythmically repeating structures. One is the secretion of the outer shell at the aperture: miniscule incrementations of calcium carbonate occur in sets of three to five, separated from preceding and succeeding sets by a ridge known as a growth line. The other rhythmic pattern is septation, by which the parts of the shell abandoned by the animal are partitioned off into chambers.

The aperture receives new growth increments at the margin, approximately half a revolution ahead of the chamber wall. The organism periodically pulls itself towards the extended aperture and deposits another septum behind it. No direct time association, therefore, exists between these two growth measures. A span of months separates the deposition of a chamber wall and the growth lines counted for that chamber. However, throughout the animal's life these septa are placed at remarkably regular intervals in the shell (Fig. 1).

As shown in Fig. 2, the number of growth lines per chamber length in *N. pompilius* is 30 ± 2 , a relationship that seems to hold throughout ontogeny. The present length of the lunar synodic month is 29.53 days. This suggests that one growth line is deposited each day and one septum is developed each lunar synodic month. While the growth rates and life habits of *Nautilus* remain to be studied extensively, the following lines of evidence suggest that this timing is reasonable. (1) Other molluscs show tidally induced or circadian skeletal banding at about the same rate of growth^{3–6}. (2) The activity cycle and

Fig. 1 Longitudinally sectioned shell of *Nautilus pompilius* showing **A**, margin of aperture where growth lines are secreted; **B**, body chamber where animal lives; **C**, septum or chamber wall; **D**, chamber space. The number of growth lines per chamber length (between arrows) can be counted using a scanning electron microscope. These counts reveal a constant number of growth lines per chamber. If our hypothesis is correct, the chambers are secreted at lunar monthly intervals.

depth migration²¹ (movement into shallow waters at night) of *Nautilus* and the attendant stress on physiology makes the expression of a daily rhythm in the skeleton seem very likely, particularly when considering the effect of periodic respiratory changes upon growth line formation²². (3) Experimentally reared cephalopods (*Sepia* and *Sepiella*) showed daily lines²³. And (4), that successive septa are formed at intervals of at least several weeks has been supported by studies of the gas content of *Nautilus* chambers^{24,25}.

Therefore, we accept as a working hypothesis the idea that the rate of secretion of growth lines is circadian, and chambers circa-lunar. Thus, one rhythm is tied to the Earth-Sun relationship, the other to the Earth-Moon.

Growth line counts

The chambered cephalopods, including nautiloids, are probably among the most accurately dated of all fossils, due to their rapid evolution and extensive preservation in sedimentary deposits around the world. Fossil nautiloid growth lines are quite easily discerned, well preserved, and unambiguous, as shown in the photographs of growth lines (Figs 4, 5). The growth rhythm of nautiloids appears to manifest itself not just in regional settings. For example *Aturia* sp. found in Australia exhibits essentially the same growth rhythm as *Aturia curvilineata* found in Florida (Table 1). As nautiloid growth lines are believed to be daily in nature and not tide-induced, determination of the nature of the tidal cycles present in the animal's habitat is unnecessary. All of the above factors fulfill criteria essential for reliable and useful nautiloid growth line counts in geochronometry.

Growth lines are present on many superbly preserved fossil specimens. Growth lines on *N. pompilius* were examined and photographed using a scanning electron microscope or a stereoscopic optical microscope with oblique light to accentuate the growth lines.

Fig. 2 Scanning electron micrograph of the growth lines present on the outer shell of a recent *Nautilus pompilius*, ventral section. The number of growth lines per chamber (between arrows) averages 30. The number of days per lunar synodic month is 29.53.

The number of growth lines per chamber was counted on 184 different chambers of 9 recent and 29 fossil nautiloid specimens (Table 1). The specimens represent nine geologic periods and a range of about 420 Myr. Figure 1 illustrates the structure of the *N. pompilius* shell, showing the location of growth line counts. Figure 2 reveals the distinct growth lines on the ventral side. All of the counts of growth lines per chamber for consecutive undamaged chambers of recent *N. pompilius* approximated 30 (Table 1). For individual chambers, the number of growth lines ranged from 28 to 34; the average for all chambers of all specimens was 30 ± 2 . The radial lirae, or ridges, on the internal layer of the initial whorl of three *N. pompilius* specimens were counted, consistently revealing 26–32 lirae per chamber (Fig. 3), an average of 29 per chamber per specimen.

As we go back in geologic time, the number of growth lines per chamber decreases. The number of growth lines per chamber had increased from 9 at 420 Myr ago to 30 today (Table 1). Three broad conclusions can be drawn from our data. First, the number of growth lines per chamber is constant for the various chambers in a single specimen. Second, many of the nautiloids living at any given time secrete the same number of growth lines per chamber. This seems to imply a ubiquitous rate of septal and outer shell deposition at any particular geologic time. Third, and most important, the number of growth lines per chamber decreases with increasing geologic age (Fig. 6).

Fig. 3 Ventral section of *Nautilus pompilius* exposing the radial lirae on the interior of the chambers of the initial whorl. The lirae correspond to external growth lines, and their number/chamber averages between 28 and 30. Arrows mark chamber walls. Scale bar, 0.5 cm.

Application to Earth-Moon system

By assuming that septal secretion was controlled in the same way for fossil nautiloids (on a lunar synodic monthly basis), we can calculate the period of the Moon's orbital motion and the Earth-Moon distance up to 420 ± 10 Myr in the past, the age of our earliest specimens. The calculations made involve the following assumptions: (1) The length of the sidereal year is assumed to be constant by virtue of the large moment of inertia of the Earth around the Sun²⁶. (2) The Earth's period of rotation is assumed to have increased at the rate of 25 s per million years, the consensus result indicated from ancient eclipse studies¹⁶, some astronomical studies²⁷, and from palaeontological studies of fossil corals¹. (3) The mass of the Earth and Moon have remained constant for the past 500 Myr. We assume also that the gravitational constant is unvarying. (4) To simplify calculations, the barycentre of the Earth-Moon system is taken as the centre of the Earth.

Although the number of days in the synodic month seems to be recorded by nautiloids, for our orbital calculations the

Fig. 4 Close-up of the outermost shell layer with growth lines on a remarkably preserved *Eutrophoceras dekayi* from the Pierre Shale of South Dakota (Upper Cretaceous, ~69.5 Myr ago). The number of growth lines per chamber (between arrows) is 22 ± 2 . If chamber secretion involves a lunar monthly rhythm, then the Moon circled the Earth every 22 days, 69.5 Myr ago. Scale bar, 1 cm.

sidereal month must be used. Following Runcorn²⁸, the relationship between the synodic month S_n , the sidereal month S , and the present year length Y , can be expressed for any geologic time as:

$$S = S_n / (1 + S_n / Y)$$

To avoid confusion originating from changes in the day length, these values are expressed in hours. Applying Kepler's third law, neglecting eccentricity, yields the semi-major axis of the Moon's orbit for any geologic time.

Mode of life of *Nautilus* and nautiloids

Nautilus pompilius Linnaeus does not crawl on the ocean bottom, but instead is an active epibenthic swimmer. Several lines of evidence point to a similar mode of life for most fossil nautiloids, particularly the development of ribbing and coiling of shells and of chambers with gas and cameral deposits to maintain the body chamber in a horizontal position. This orientation would be essential for any nautiloid to propel itself effectively.

Three species, *Welleroceras liratum* Miller and Furnish, *Pseudorthoceras knoxense* McChesney, and *Orthoceras unicaera*, did not fit the general trend shown in Fig. 6. However, counts for these shells did possess integral multiples of the predicted number of growth lines per chamber length. One

Fig. 5 Dorso-ventral section of an orthocerid ~326 Myr old. The arrows mark the different chamber walls. There are a constant 15 ± 1 growth lines per chamber, the same number possessed by other nautiloid genera from almost time equivalent Mississippian formations. Scale bar, 1 cm.

species, *Pseudorthoceras knoxense*, had growth lines grouped together in threes, and the number of growth line groups was equal to the growth line counts of other specimens of that time. The evidence suggests that the modes of life of these three nautiloid species did not resemble that of modern *Nautilus*. Though depth ranges of fossil cephalopods are difficult to establish²⁹, we suggest, based on morphologic³⁰ and palaeo-ecologic studies³¹, that these three, each displaying weak septa, may have been restricted to a relatively shallow shelf and inland sea habitat (50–100 m depth). In addition, the *Welleroceras liratum* may not have been able to maintain a horizontal orientation and may have moved by crawling with its tentacles³¹. How strongly their ecologic niche was influenced by tidal interference and if this is reflected in their growth pattern is not known. Thus, specimens with relatively weak septa and/or inability to maintain the body chamber in a horizontal position could not be active deep water swimmers like *Nautilus*. Those fossil specimens of the orders Orthocerida and Nautilida that fit the growth trend are considered to have withstood similar depths as recent *Nautilus*³⁰.

The eyes of *Nautilus*, like those of other cephalopods, are quite sensitive to variations in amount of light, despite the absence in *Nautilus* of iris, lens, and eyelid³². Large numbers of cephalopods migrate upwards at night³³, and *Sepia* becomes so buoyant in darkness that it cannot help but rise³⁴. As for *Nautilus*, its activity has been reported^{21,31}, although not confirmed¹⁹, to be related to light and darkness with the animal becoming active at sunset and migrating nocturnally to lesser depths.

Whether the *Nautilus* secretes growth lines and septa during the day, when it rests in deep water, or at night, when it actively feeds, remains unknown. A theory of molluscan growth line formation based on respiratory changes²² would imply that the growth increments are reflections of alternating periods of shell deposition and dissolution occurring during aerobic and anaerobic respiration, respectively. It might be speculated that for *Nautilus* the aerobic respiration occurs at night in warmer, shallower water, with anaerobic respiration during the day in colder, deeper waters. The issue of daily migratory habits that this latter thesis implies remains at present unresolved^{19,21,31}.

Other astronomical evidence

Other astronomical measurements of changes in the lengths of the day and the lunar distance may be compared to those obtained from our study of nautiloid growth rhythms. The short-term astronomical approach utilises careful measurements of the Moon's position through occultations timed by atomic clocks¹⁵. Although astrometry can determine precisely the rotation rate of the Earth, it cannot give the secular acceleration because, over periods from a few days to several centuries, the acceleration is dominated by non-cumulative fluctuations²⁶. Historical records of ancient solar eclipses¹⁶ provide a means of studying the evolution of the Earth–Moon system for the past 3,000 yr. This approach yields clear evidence that the lunar orbit and the length of the day have increased during this period. The lunar laser ranging experiment can now measure the distance to the Moon with an accuracy of about half of the predicted yearly lunar recession³⁵, and thus will soon be able to provide direct data on changes in the lunar distance.

From the ancient eclipse study¹⁶, the rate of change in the lunar orbit semi-major axis is $\dot{a}/a = 1.5 \times 10^{-10}$ parts yr^{-1} , or a recession of the Moon of 5.8 cm yr^{-1} . The value for the Earth–Moon distance 69.5 Myr ago is 0.840 times the present distance (Fig. 6). This implies an average change in the lunar orbit semi-major axis of 26.6×10^{-10} parts yr^{-1} or an average recession of 94.5 cm yr^{-1} . This is 17 times the rate from the ancient eclipse studies and implies (if this rate is the correct long-term one) that the recent dissipation is not typical for past geologic time and that additional energy sinks may be involved.

The unfortunate problem inherent in the astronomical approach is that there is no way of knowing whether the last few

decades of lunar orbital evolution, or even the last few thousand years, are typical of the evolution which occurred over geological times. To extrapolate from a few thousand years to several hundred million is quite risky. Whether the rate of lunar orbital change for the last few thousand years is a 'minor fluctuation' compared to the millions of years of geologic time is not easily determined.

The only 'long-term' study (on a time scale of millions of years) is Wells' palaeontological study¹ on daily and annual banding in corals, the results of which suggest a much slower lunar recession than the nautiloid data does. Although the existence of annual banding on corals is well established, there is some question about daily banding in modern corals. We have seen no research indicating daily bands, except for Wells'

Fig. 6 Plot of the number of growth lines per chamber length and Earth-Moon distance against geologic time showing the tendency towards increase in the number of nautiloid growth lines/chamber with time. The points are fitted by a third degree polynomial least squares fit. Note the consistency with which nautiloids of each era have the same number of growth lines per chamber, with the only exceptions being the three specimens of Carboniferous age, which reflect multiple integrals of the predicted constant number. Independent evidence suggests that these species, in contrast to the other nautiloids studied, lived in a shallow water regime subject to tidal interference. Vertical error bars mark the maximum discrepancy between any single growth line count and the average for the specimen. The horizontal width of each error bar reflects the uncertainty in the dating of each fossil. For changes in the Earth-Moon distance based on the nautiloid data (right scale), the steep slopes in the curve may represent higher tidal energy dissipation during the last 70 Myr as well as from 325–420 Myr ago. About 375 Myr ago the Moon was about one-half its present distance from the Earth.

observation of one coral species in which this seems to occur. Usually incomplete lunar monthly cycles reflect more the coral's environment of growth than lunar periodicity³⁶. Other researchers report that the maximum density of reef coral skeletons is only associated with periods of above average seawater temperature³⁷. Growth patterns vary considerably among modern individual corals, even of the same community³⁸. The potential of corals as geochronometers is seriously limited by the absence of daily and monthly growth patterns in vertical sections of coral skeletons³⁹.

The nautiloid data can provide long-term evidence for the length of the day. By assuming only that the angular momentum of the Earth-Moon system is conserved, the lengths of the day and month are tied inseparably to one another, and, therefore, are both established by the nautiloid data. The past length of the day has not been established by any other growth studies. Calculations on the length of day are being done and will reduce, when substituted into the Runcorn equation, the palaeo-lunar distances in Table 1 and Fig. 6.

Rate of lunar orbital evolution

A synthesis of palaeomagnetic data, stratigraphic relationships, and studies of environments of sediment deposition have led to a reconstruction of Mesozoic and Palaeozoic continental configurations³⁹, however, much more exact and extensive information on ocean profiles is required for even an order of magnitude determination of ancient tidal energy dissipation. Since the magnitude of tidal dissipation depends so strongly on ocean configurations and depths^{40,41}, theoretical extrapolation of the lunar orbit into the past becomes an impossible task⁴¹. Given this limitation, it is still a generally accepted characteristic of lunar orbital evolution that it proceeded most rapidly when the Earth and the Moon were closer together. Tidal forces were then greater because the tidal torque is proportional to $a^{-11/2}$ (ref. 14). This means that the orbit would have quadrupled in size in the first 10 Myr if the Moon originally had been near the Roche limit. However, when the present astronomically determined rate of the Moon's recession is extrapolated back in time, the Moon approaches the Roche limit less than 10^9 yr ago, according to Kaula¹³, and a lunar surface melt would have occurred due to tidal energy dissipation. There is no lunar or terrestrial geologic evidence to support such a close approach at that time, since the youngest rocks on the Moon were crystallised 3.25×10^9 yr ago. This represents a time scale problem which has not been satisfactorily explained.

The change in the Earth-Moon distance shown in Fig. 6 does not proceed at a constant rate, but exhibits rather several slopes, with the slope being most gentle when the continents were not

separated, 225 Myr ago. This may reflect less active mid-ocean ridges, a lower sea level, and thus a corresponding decrease in tidal friction, as well as a decrease in the rate of retreat of the Moon from the Earth⁴²⁻⁴⁴.

The recession rate of the Moon during the last 420 Myr, based on nautiloid data, varies by a factor of less than 3, which does not support a recession rate varying by $a^{-11/2}$. This supports the explanation of the time scale problem in terms of changing palaeogeography. As Kaula¹³ points out, the formation of Pangea at a high latitude would lead to lower tidal dissipation. If tidal dissipation takes place mainly in shallow seas, then a lowering of sea level to a depth below the present day continental shelves could conceivably reduce the tidal dissipation⁴¹. However, the establishment of even non-tidal oceanic circulation patterns in the past is extremely difficult.

If the Moon originally was near the Roche limit about 4×10^9 yr ago, as Lowman⁴⁵ and others have proposed, then the orbit must have evolved slowly for the Moon to be at half of its present distance 375 Myr ago, in the Devonian, as our calculations show. This slower evolution can explain why the lunar maria are concentrated on the near side of the Moon, as well as why the Moon's centre of mass is displaced earthwards relative to its figure. If slower evolution occurred, the Moon may have been close enough to the Earth for gravitational accelerations asymmetric to the centre of the Moon to influence magma extrusion 3.5 to 4.0×10^9 yr ago⁴⁶. Certain aspects of the Witwatersrand sediments, deposited 2×10^9 yr ago, may be explained by larger tides due to a smaller Earth-Moon distance⁴⁷. Studies of Precambrian stromatolites^{48,49} suggested that greater palaeotides existed until 1.7×10^9 yr ago, a feature unexplainable if the Earth-Moon distance increased rapidly early in the system's history⁵⁰. It is difficult to extrapolate beyond the 420 Myr of nautiloid data without an understanding of why the recession does not vary inversely as the $11/2$ power of lunar distance. One must also explain why the recession rate observed in historical times is so much smaller than the long-term average shown by nautiloid data for the past 70 Myr.

A recent summary of geologic evidence on the accretion of continents⁵¹ provides new support for the idea of a lunar orbit slowly expanding from about 4×10^9 yr ago until the Cambrian. One or a few supercontinents may have accreted gradually beneath a globe-encircling ocean in the Precambrian, with the continent(s) emerging only 600 Myr ago, at the beginning of the Cambrian. We, therefore, support the existence of three stages in the dynamical evolution of the Earth-Moon system. First, at a time when liquid water was not present on the surface of the Earth, the lunar orbit evolved slowly due to tides in the solid Earth and Moon. Next, the Moon continued to recede slowly

because the deep sea encircling and covering the continents dissipated little energy. Then, about 600 Myr ago, when the continents emerged, the last stage began, and lunar recession proceeded more rapidly.

DNA Sequence of the mini-insertion IS2-6 and its relation to the sequence of IS2

Debabrota Ghosal & Heinz Saedler

Institut für Biologie III, Universität Freiburg, Schanzlestr. 1, D-7800 Freiburg i.Br., FRG

In polar orientation IS2 abolishes galactose operon expression. Operon activity is restored by a 108 base pair mini-insertion within IS2 called IS2-6. The DNA sequences of the gal operon-IS2 junction, the parental IS2 region undergoing sequence rearrangements and IS2-6 itself are reported. IS2-6 is composed of sequence intervals present in both strands of IS2.

It is known that IS2 occurs in multiple copies in the *E. coli* chromosome¹ and to transpose to various sites in the same or other replicons, at which it sometimes induces mutations². The analysis of such mutations revealed that IS2 can influence the expression of adjacent genes in two different ways depending on its orientation of integration^{3,4}. For example, when integrated into the control region of the galactose operon of *E. coli* in orientation I, IS2 turns off the expression of the *gal* genes downstream in the direction of transcription; in the opposite orientation (orientation II) it efficiently turns them on. We have further shown that an IS2 element integrated in polar orientation (orientation I) can undergo internal changes that also lead to constitutive expression of neighbouring genes, although the gross orientation of the element remains unaltered^{3,5}.

To study the internal changes within IS2 more precisely, a recombinant plasmid, pDG1, was constructed, containing the galactose operon of *E. coli* K12 within the plasmid pSC101. IS2 was then transferred to plasmid pDG1 by homogenote formation, generating the mutation *galOP*-308::IS2. This new plasmid, harbouring IS2 in polar orientation in the control region of the galactose operon is called pDG12. A strain carrying a deletion in the *gal* region of the *E. coli* chromosome was transformed with pDG12 and used for further genetic manipulations⁵. At 37°C Gal⁺ revertants of this strain are observed with a frequency of 3×10^{-7} . Among 109 such Gal⁺ revertants analysed 102 exhibited inducible synthesis of *gal* operon specific enzymes, indicating that the wild-type *gal* operon had been restored, most likely due to accurate excision of the integrated IS2 element. This has been verified for one such inducible revertant⁵. However, seven clones were found to be constitutive for *gal* enzyme synthesis, suggesting that other events had led to reactivation of the *gal* operon. The seven constitutive Gal⁺ revertants fall into three groups: Class 1 consists of one revertant, which was shown by genetic means to be due to a highly unstable suppressor located on the bacterial chromosome. Class 2 contains three revertants which show no gross alterations within IS2, as judged by analysis of DNA fragments produced by various restriction endonucleases. These revertants are stable.

Class 3 consists of three further revertants which are characterised as being highly unstable. These were previously shown to be due to the addition of small DNA segments within IS2. Revertant R1 contains an insertion of 115 base pairs, while in R3 a 65-base pair DNA addition was observed. These mini-insertions were previously termed IS6 and IS7 respectively⁵. We report here the DNA sequence of part of IS2 and of IS6. These results indicate that IS6 can be considered an allele of IS2. Therefore it will henceforth be called IS2-6. The DNA sequence of IS2 and IS2-6 reported here suggests a model for the formation of mini-insertions.

Mapping of IS2-6

In an earlier report the presence of additional DNA within IS2 in two unstable constitutive Gal⁺ revertants of *galOP*-308::IS2 on pDG12 was shown by agarose gel electrophoresis of DNA fragments produced by restriction enzymes⁵. The relevant DNA fragment used in that study was produced by restriction endonuclease *Hind*III.

Fig. 1 Electrophoretic banding patterns of the *Hind*III DNA fragments of pDG12 (IS2) and pDG12 R1 (IS2-6), which are 895 and 1,010 base pairs long respectively⁵, after *Hinf*I and *Hae*III digestion. Slot 1, *Hinf*I digestion of pDG12 DNA, band *a*, *b*, and *c* correspond to 435, 282, and 153 base pairs respectively. Slot 2, digest of pDG12 R1 with *Hinf*I. Note the shift in molecular weight of band *a* (435 base pairs) to *a'* (542 base pairs). The presence of *a* material in pDG12 R1 is due to Gal⁺ segregants present in the DNA preparation. All other bands are unaffected by mutation R1. Slot 3, Marker λ dv-1 digested with restriction endonuclease *Hae*III. From bottom to top the molecular weights of the bands correspond to 120, 136, 150, 180, 185, 210, 240, (286, 331), 451, 481, 1,000, 1,325, and 1,460 base pairs respectively⁸. Slot 4, DNA fragments of pDG12 R1 produced by *Hae*III endonuclease. Bands *a*, *b*, *c''* and *c'* correspond to 430, 340, 207, and 153 base pairs respectively. Slot 5, pDG12 *Hae*III fragments. Bands *a*, *b*, and *c* correspond to 430, 340 and 99 base pairs respectively. Plasmid DNA from pDG12 and pDG12 R1 was prepared as described previously⁵. Preparative isolation of *Hind*III fragments was performed using 6–8 mm thick agarose slab gels (1%); gel strips containing the bands were cut out and DNA was extracted^{9,10}. DNA was pelleted by adding 0.3 M Na-acetate was 2.5 volumes of ethanol. For terminal labelling and further enzymatic cleavage this DNA was purified by one cycle ethidium bromide–CsCl buoyant density gradient centrifugation. Digestion of the DNA (0.5–1.0 μ g) with restriction enzymes *Hinf*I and *Hae*III was performed in 10 mM Tris–HCl buffer pH 7.6, 10 mM MgCl₂, 1 mM DTT, 50 mM NaCl, and 0.1 mM EDTA, and 100 μ g ml^{–1} carboxymethylated BSA. The digest was adjusted to 10 mM EDTA and 10% glycerol, 0.05% bromophenol blue was added, and the mixture was subjected to electrophoresis on 10% polyacrylamide slab gels in 40 mM Tris-acetate buffer pH 8.3 for 2–3 h at 110 V. The gels were stained in water containing 2 μ g ml^{–1} ethidium bromide for 10–15 min. The gel was then photographed under ultraviolet light.

While the *Hind*III fragment generated from plasmid pDG12 is 895 base pairs long, the corresponding fragment produced from DNA presumably carrying IS2-6 (pDG12 R1) is 1,010 base pairs long. When the *Hind*III fragment from pDG12 is further digested with *Hae*III endonuclease, three smaller frag-

Fig. 2 Detailed restriction map of the 895-base pair⁵ *Hind*III DNA fragment of pDG12. The pertinent sites for cleavage by restriction endonucleases *Hind*III, *Hae*III, and *Hinf*I are shown, including one *Hpa*II site. The *Mbo*I sites are inferred from the sequencing data, but the enzyme does not cleave at these positions (see text). The map was established by digesting the *Hind*III fragment with one enzyme and comparing this with the reciprocal double digest of combinations of various other enzymes. The *Hinf*I and the *Hae*III fragments *a*, *b*, and *c* are given below the map. When terminally labelled *Hind*III fragment of pDG12 is digested with *Hae*III (see Fig. 1, slot 5) fragments *a* and *b* contain the label at one of their 5'-ends, while fragment *c* is not labelled. This shows that fragment *c* is derived from the interior part of the *Hind*III fragment. The position of fragment *a* can readily be identified since it contains the known *Hind*II cleavage site within *galE* (ref. 5). *Hinf*I digestion of the *Hind*III fragment also yields three fragments *a*, *b*, and *c* (see Fig. 1, slot 1). Digestion of *Hae*III fragment *a* with *Hinf*I yields a 153- and a 275-base pair fragment. Digestion of terminally labelled *Hae*III fragment *c* with *Hinf*I generates a 7- and a 92-base pair fragment. This shows that one *Hinf*I cleavage site is located in *galE*, while the other is close to a *Hae*III site within IS2. The only *Hpa*II site shown is generated after digestion of the 282-base pair long *Hinf*I fragment *b* and thus maps at a position already described^{11,12}. The total length of the *Hind*III fragment as determined by the sum of the proper fragments is 873 instead of 895 base pairs as determined previously⁵.

Fig. 3 Autoradiograms of sequencing gels. *a*, [^{32} P]*Hinf*I/*Hae*III fragment from nucleotide 18–74 of IS2. *b*, [^{32} P]*Hae*III/*Hinf*I fragment from 106–52 of IS2. Both sequences read from the labelled 5'-end and represent complementary DNA strands. The sequences overlap at 53–74. About 10–20 pmol of *Hae*III or *Hinf*I fragments of either IS2 or IS2-6 were dephosphorylated with 0.5–1 unit of bacterial alkaline phosphatase (Worthington, phenolysed, ether extracted and ethanol precipitated). Fragments were labelled using [γ - ^{32} P]ATP (1,000–3,000 mCi mmol $^{-1}$, NEN) and 2 units of polynucleotide kinase (Boehringer Mannheim). The doubly labelled fragments were separated on a polyacrylamide gel and the corresponding bands were eluted. These were redigested with either *Hinf*I or *Hae*III to yield a fragment labelled at only one 5'-end. DNA sequencing was performed by partial methylation (for G), controlled partial hydroxymethylation (for C and T) and strong alkaline treatment at 90°C (for A>C) followed by strand scission as described in ref. 6. Products were analysed in 15 or 20% denaturing polyacrylamide gels using Tris-borate-EDTA buffer followed by X-ray autoradiography.

ments (*a*, *b*, and *c*) are generated (Fig. 1, slot 5). However, digestion of the 1,010 base pair long fragment of pDG12 R1 with restriction endonuclease *Hae*III yields three major (*a*, *b*, and *c*), slot 4) and two minor DNA fragments (*c* and *c'*, slot 4). Fragment *c*, not visible in Fig. 1, is identical in size and sequence to the 99 base pair long fragment *c* of pDG12. It is generated by molecules which have lost the mini-insertion within IS2. Frequent spontaneous loss is characteristic of IS2-6. The amount of fragment *c* found in pDG12 R1 preparations correlates with the number of Gal $^{-}$ segregants among cells harbouring plasmid pDG12 R1 (ref. 5).

Fragment *c'* is 153 base pairs long. It is a deletion derivative of IS2-6 and accumulates in cultures with time. Its isolation, properties, and DNA sequence will be reported elsewhere (Ghosal and Saedler, manuscript in preparation).

Two of the three major fragments (*a* and *b*) of the parental and the Gal $^{+}$ constitutive revertant plasmid DNA pDG12 R1, are identical in size. Fragment *c* of pDG12 is 99 base pairs long while the corresponding fragment of pDG12 R1, fragment *c'*, is 207 base pairs long. The mini-insertion IS2-6 is therefore 108 base pairs long and has arisen by insertion within the small

*Hae*III fragment *c* of pDG12, yielding fragment *c''* of pDG12 R1. Both fragments, *c* and *c''*, (Fig. 1) have been used for DNA sequence analysis.

The location of *Hae*III fragment *c* within IS2 and with respect to the most proximal *gal* structural gene is shown on the restriction map of the 895-base pair long *Hind*III fragment of pDG12 presented in Fig. 2.

DNA sequence of part of IS2

The DNA sequence between the *Hpa*II site and the rightmost *Hae*III cleavage site on pDG12 (Fig. 2) was determined using the procedure described by Maxam and Gilbert⁶.

In one set of experiments the *Hind*III fragment of pDG12 carrying *galOP*-308::IS2 was isolated and digested with *Hae*III endonuclease. The mixture of three smaller fragments which results was dephosphorylated and the 5'-ends were labelled with [γ - ^{32} P]ATP using polynucleotide kinase. Fragment *c* (see Fig. 1) was isolated and its labelled strands separated by gel electrophoresis. These were subsequently sequenced.

In an alternative procedure, the labelled *Hae*III fragment *c* was further digested with *Hinf*I. The larger 92-base pair frag-

ment labelled at its *Hae*III end was isolated and sequenced. For determination of the sequence of the complementary DNA strand, the *Hind*III fragment was first cleaved with *Hinf*I. The mixture of the three fragments generated (see Fig. 1) was labelled and subsequently digested with *Hae*III. In this case the 92-base pair fragment is labelled at its *Hinf*I end. This fragment was isolated and sequenced.

The sequencing gels of the latter two fragments are presented in Fig. 3*a* and *b*. The sequences obtained with both procedures are identical except for 7 base pairs to the left of the *Hinf*I cleavage site, which are missing in the *Hinf*I-*Hae*III fragments. The complete sequence of the *Hae*III fragment *c* is included in Fig. 5.

Two *Mbo*I sites are detected by the sequencing method. However, *Mbo*I does not cleave at these positions. This seems to

indicate that the *Mbo*I sites are modified in this bacterial background. This agrees with observations by others that the *Mbo*I cleavage site is modified in *E. coli* K12.

Integration site of IS2

On cleavage with *Hinf*I the *Hind*III fragment yields three smaller fragments as shown in Fig. 1, slot 1. The 282-base pair fragment *b* contains the junction between IS2 and the *gal* operon. Labelling both 5'-ends and subsequent digestion with *Hpa*II yielded a fragment suitable for sequencing. The DNA sequence of the integration site of IS2, which also contains the *gal* mRNA leader sequence and the total sequence of the *Hae*III fragment *c* is included in Fig. 5. It can be seen that IS2 has integrated next to the initiation site for *gal* mRNA tran-

Fig. 4 IS2-6 was sequenced by the methods described in the legend to Fig. 3. *a*, DNA sequence of the labelled IS2-6 *Hinf*I fragment *a'* cleaved with *Hae*III, from position 36-128. *b*, DNA sequence of the complementary DNA strand of IS2-6 from 201-116 (labelled *Hae*III fragment *c''*, cleaved with *Hinf*I). The overlapping region is thus 13 base pairs long.

Fig. 5 Sequences with negative numbers represent material from the galactose operon, others are IS2 and IS2-6 sequences, respectively. The vertical bar in the top line separates the *gal* from the IS2 sequences. The arrows above the sequences indicate direct sequence repetitions, while the arrows below the sequences show the inverted repeats. For IS2 the small inverted repeats are numbered from top to bottom. The connecting lines between IS2 and IS2-6 show the length and the position of the 108-base pair insert of IS2-6.

scription. Thus in mutation *galOP*-308, IS2 disconnects the mRNA initiation site from the *gal* promoter. Comparison with the sequence of the operator proximal end of IS2 reported for *galOP*-490::IS2 (ref. 7) reveals that in both strains IS2 has integrated into the control region of the *gal* operon, but at two different sites, separated by one nucleotide. In addition the comparison also reveals that the termini of IS2 correspond to imperfect inverted repeats.

Features of the IS2 sequence

Figure 5 also shows that there are a few small direct and inverted repeats in the sequence of the *Hae*III fragment *c* of IS2. Six pairs of inverted repeats are present. It should be noted that the sequence between the left end of pair 3 and the right end of pair 5, that is, nucleotide pair 33 to nucleotide pair 78, is especially rich in A-T (76%), while the A-T content of the flanking sequences is about 50%.

Features of the sequence of IS2-6

The same strategy has been used to analyse IS2-6, the *Hae*III fragment containing IS2-6, being 207 instead of 99 base pairs long.

The sequencing gels for the *Hinf*II/*Hae*III fragments are given in Fig. 4a and b. The DNA sequence obtained is included in Fig. 5. Except for the modified *Mbo*I sites already seen in the IS2 sequence, no other new cleavage sites for restriction endonucleases are found in IS2-6.

The most striking feature of the IS2-6 sequence is the high degree of symmetry. The large inverted repeat is 62 base pairs long and is substructured as indicated. In addition there is large perfect duplication of 46 base pairs in length as well as five smaller imperfect direct repeats. The A-T content between positions 33 and 186 is 76%.

Comparison of IS2 and IS2-6

Figure 5 shows that IS2-6 constitutes an insertion of 108 base pairs within IS2 at either position 78/79 or position 44/45. Assuming position 78/79 to be the point of DNA addition, it is clear that the 108 base pairs of IS2-6 are derived from sequences of IS2 located between positions 33 and 78, that is, from IS2 material contained between the inverted repeat pairs 3 and 5.

However, IS2-6 does not consist of a simple duplication of IS2 sequences from these regions. Instead sequences of both IS2 strands located within the 33-78 interval are multiplied and rearranged in the manner outlined in Fig. 6. Some IS2 sequences are represented several times in both possible orientations in IS2-6. The 53-60 region of IS2, for example, recurs five times, while the pairs of inverted repeats 3 and 5 are found three times and in both orientations.

Mode of formation of IS2-6

One explanation of how the complicated structure outlined in Fig. 6 might have arisen is that recombinational events occurred between the two DNA strands of IS2 during replication.

Fig. 6 The coordinates of one DNA strand of IS2-6 are given. The numbers below the line are the coordinates of IS2, indicating which sequences of IS2 are present in the IS2-6 sequence. The arrows emphasise the orientation of the sequence.

However, the high degree of symmetry observed in IS2-6 suggests another mechanism of formation based exclusively on replication. This mode of formation will be described briefly (Fig. 7) as it enables predictions to be made about the sequences of other replication products that would be expected to occur.

Considering the replication of the lower DNA strand of IS2 only, the DNA synthesising enzyme may be imagined to proceed from the 5'-end across the inverted repeat at position 33/52 (pair number 3) to position 78 (Fig. 7a). Because of the high A-T content of this region, partial melting might occasionally

Fig. 7 Slippage replication of the lower DNA strand of IS2 (upper frame) indicate the positions of the inverted repeat pairs 3 and 5 (see Fig. 5), which are marked by heavy arrows throughout. The hypothetical sequence of events (a-e) leading to the replication products IS2 and IS2-6 are enclosed by a black line. For simplicity only the DNA sequences separating both parts of an inverted repeat pair are shown. e, dotted and dashed lines indicate DNA synthesised after a second round of slippage of the DNA template. The segregation products of the heteroduplex formed are presented in the lower frame as IS2 and IS2-6. See text for details.

occur (Fig. 7b). Subsequently inverted repeat pair 5 of the newly synthesised DNA strand could fold back on itself forming a new template for further DNA synthesis (Fig. 7c). The polymerase could then proceed in the 3' direction along the newly synthesised strand until it passes inverted repeat pair 3 and reaches position 33 (Fig. 7d). At this point the same slippage process is repeated: melting out, folding back of the inverted repeat pair 3 and DNA synthesis along the newly made DNA strand leading to the structure shown in Fig. 7e. This slippage tends to form long inverted repeats. Occasionally these may resist partial melting out so that DNA synthesis can then proceed along the old parental DNA strand, provided that inverted repeat pair 3 (33–52) in the parental DNA strand has folded up as indicated in Fig. 7e to yield a stable structure.

On another round of replication the DNA heteroduplex molecule forms two segregants, the old parental IS2 sequence and the newly generated IS2–6 allele.

The slippage of the DNA template during replication of IS2 as outlined in Fig. 7 generates symmetrical DNA additions (see Fig. 5). The process requires, first, a DNA region rich in A–T, and second, pairs of inverted repeat sequences at both ends of the A–T rich region. The newly formed sequences generated by this process may contain new signals for the turn-on of gene expression, as shown by IS2–6. Which parts of the IS2–6 sequences constitute the turn-on signal is not yet known.

The replication 'slippage' model described in Fig. 7 for IS2–6 allows us to predict the DNA sequence of the replication 'slippage' product of the upper DNA strand of IS2. Since preparation of this manuscript we have determined the sequence of the 54-base pair mini-insertion IS2–7. Its sequence is identical to the slippage product predicted for replication of the upper strand of IS2 and will be reported elsewhere¹³.

We thank Gudrun Hoeksma for technical assistance and Patricia Nevers for reading the manuscript. This work was supported by the Deutsche Forschungsgemeinschaft.

The construction and analysis of bacterial plasmids that contain and phenotypically express a mammalian genetic sequence are described. Such plasmids specify a protein that has enzymatic properties, immunological reactivity and molecular size characteristic of the mouse dihydrofolate reductase, and render host cells resistant to the anti-metabolic drug trimethoprim.

SINCE the initial propagation of eukaryotic DNA in bacteria¹, several systems have been used to study the expression in *Escherichia coli* of DNA derived from higher organisms. Biological activity of genes from the lower eukaryotes, *Saccharomyces cerevisiae*^{2,3} and *Neurospora crassa*⁴, has been demonstrated using phenotypic selection for functions that complement mutationally inactivated homologous bacterial genes. Immunological reactivity with antibody made against human somatostatin was shown for a peptide fragment cleaved *in vitro* from a hybrid protein encoded in part by bacterial DNA and in part by a chemically synthesised somatostatin DNA

sequence⁵. Very recently, a protein containing amino acids of rat proinsulin was shown to be made by bacteria that carry a double-stranded complementary DNA (cDNA) transcript of pre-proinsulin mRNA⁶; in that instance, antigenic determinants for both insulin and the bacterial enzyme β -lactamase were detected on a fused peptide transported outside the cell. It is not known, however, whether the mammalian peptide components of such immunologically reactive hybrid proteins have functional biological activity.

Our approach to the study of mammalian gene expression in bacteria has been to generate a heterogeneous population of clones carrying a DNA sequence that codes for a selectable mammalian gene product, and then to select directly those bacteria in the population that phenotypically express the genetic sequence. The mammalian enzyme dihydrofolate reductase (DHFR), which catalyses the conversion of dihydrofolic acid to tetrahydrofolic acid, is especially suitable for this purpose. The mammalian DHFR has a much lower affinity for the antimetabolic drug, trimethoprim (Tp), than does the corresponding bacterial enzyme⁷. Thus, bacteria which biologically express mammalian DHFR activity are resistant to levels of trimethoprim that ordinarily inhibit growth.

When these studies were initiated, the only bacterial host approved for EK2 recombinant DNA experiments⁸ was *E. coli* K12 strain χ 1776 (ref. 9). As this strain is already resistant to

high concentrations of trimethoprim because of its *thy*⁻ mutation¹⁰, direct selection of bacteria that synthesise the mammalian DHFR could not be carried out. Therefore, our initial studies used an *in situ* hybridisation procedure¹¹ to identify χ 1776 clones which carried a mouse DHFR cDNA sequence, with the expectation that a highly sensitive indirect radioimmunoassay¹² would be used to detect any clones that expressed antigenic determinants of the protein product encoded by the gene.

Construction and cloning of chimaeric plasmids containing a DHFR ds cDNA

Figure 1 summarises the experimental scheme used in this study. Partially purified mRNA containing DHFR sequences from methotrexate-resistant AT-3000 mouse cells¹³ was used in the preparation of double-strand (ds) cDNA by RNA-dependent DNA polymerase (reverse transcriptase) and DNA polymerase I (ref. 14 and Fig. 2). Homopolymeric deoxy-C 'tails' were added to the unfractionated cDNA by terminal deoxynucleotidyl transferase (Fig. 2) and the section of the gel containing the predominant (1,500 base pairs) tailed cDNA was eluted. The material recovered from the gel was annealed with an equimolar concentration of pBR322 plasmid DNA that had been cleaved in the β -lactamase gene by the *Pst*I endonuclease¹⁵ and treated with terminal transferase to add homopolymeric dG tails at the cleavage sites. The extent of annealing of DHFR ds cDNA with the plasmid vector was monitored by electron microscopy¹⁶ using circle formation as an indicator. *Pst*I sites are regenerated at both ends of the insert as a result of such recircularisation^{17,18}.

Constructed chimaeric plasmids were introduced into MnCl₂-treated¹⁹ *E. coli* K12 strain χ 1776 and tetracycline (Tc)-resistant transformants (yield ~30 colonies per ng DNA) were selected and tested separately for the presence of a DNA species complementary to a highly purified DHFR cDNA probe. About 40% of the Tc-resistant clones gave a positive reaction by an *in situ* hybridisation test¹¹ (Table 1 and Fig. 3). Plasmids from 14 of the reacting clones were examined by gel electrophoresis and all were found to contain a single DNA insert approximately 1,500 base pairs in length. As both ends of the *Pst*I-cleaved pBR322 DNA receive homopolymeric dG tails, only those molecules that have acquired a dE-tailed cDNA insert or had escaped cleavage and/or dG tailing would be expected to re-circularise and transform; thus, we presume that most of the nonreacting

Fig. 1 Scheme used for cloning and expression of mouse DNA sequences that code for DHFR. Additional experimental details are given in the legend to Table 1 and in the text.

Tc-resistant colonies contain inserts of contaminating non-DHFR cDNA.

When χ 2282, a *thy*⁺ variant of χ 1776, was approved for EK2 use, direct selection of bacteria that phenotypically expressed the eukaryotic DNA sequence became feasible (see Fig. 1). Two populations (25 colonies each) of previously identified Tc-resistant colonies of χ 1776 were pooled, and plasmid DNA extracted from these populations was introduced by transformation into χ 2282. In other experiments, we transformed χ 2282 directly with annealed pBR322-DHFR cDNA (Table 1). Colonies that expressed resistance to both Tc and Tp were obtained in both types of experiments; three independent

Table 1 Transformation experiments using χ 1776 and χ 2282

Host	Transforming DNA		Transformants per ng DNA			<i>In situ</i> hybridisation with DHFR cDNA probe (% positive)
	Plasmid vector	Insert	Tc (5 μ g ml ⁻¹)	Tc (10 μ g ml ⁻¹)	Tc/Tp (5 μ g ml ⁻¹ of each)	
χ 1776	pBR322	None	4 $\times$ 10 ²	2 $\times$ 10 ²	<2 $\times$ 10 ⁻³	—
χ 1776	pBR322	cDNA(1°)	60	32	—	40
χ 2282	pBR322	cDNA(1°)	70	—	2	44
χ 2282	pBR322	cDNA(2°)	60	—	1.3 $\times$ 10 ⁻¹	—
χ 2282	pDHFR7	—	75	—	25	—

pBR322 plasmid DNA that had been annealed *in vitro* with dC-tailed DHFR cDNA (designated 1°) was introduced into χ 1776 or χ 2282, using a modification of a previously described transfection procedure¹⁹. 1 ml of an overnight bacterial culture was inoculated into 100 ml of L broth supplemented with diaminopimelic acid (DAP, 50 μ g ml⁻¹) and (for χ 1776 only) thymidine (4 μ g ml⁻¹). Bacterial cultures were grown until exponential phase at 35°C and then collected by centrifugation at 4°C. Cells were washed in 0.3 volume 10 mM NaCl, resuspended in 30 ml freshly prepared MCN buffer (70 mM MgCl₂; 40 mM sodium acetate, pH 5.6, and 30 mM calcium chloride) and chilled on ice for 20 min. Cells were collected, resuspended in 1 ml MCN and added in 200- μ l aliquots to 50 μ l DNA in TEN (10 mM Tris-HCl, pH 7.5, 0.1 mM EDTA, 50 mM NaCl) or MCN buffer. After chilling at 0°C for 30 min, reactions were incubated at 27°C for 5 min, chilled again for 30 min, and 50- μ l samples were plated on to Penassay broth agar supplemented with DAP, thymidine (for χ 1776), and antibiotics as indicated. When χ 2282 was used, the selective medium was M9 minimal agar supplemented with 0.5% casamino acids, biotin (2 μ g ml⁻¹), DAP (50 μ g ml⁻¹) and Tp (2.5–10 μ g ml⁻¹) plus tetracycline (Yc) or kanamycin (Km) as indicated. Plates containing transformants were incubated at 32°C and colonies were scored 2–3 d after plating. pBR322 plasmid DNA lacking the cDNA insert was used as a control. cDNA preparations labelled as 2° consisted of plasmid DNA isolated from a nonfractionated population of clones that had previously been transformed with chimaeric molecules carrying a cDNA insert. In the experiment shown in the last line the transforming DNA was isolated from a clone (pDHFR7) that expresses resistance to Tp as well as Tc.

Fig. 2 Preparation and characterisation of DHFR cDNA insert. DNA complementary to DHFR mRNA was synthesised essentially as described elsewhere¹⁴, using avian myeloblastosis virus (AMV) reverse transcriptase and polysomal RNA obtained by indirect immunoprecipitation of DHFR-synthesising polysomes from methotrexate-resistant AT-3000 S-180 mouse cells¹³. The RNA had been estimated to contain DHFR mRNA as 20% of its mRNA¹³. The reaction was carried out in 100 μ l using 340 μ g polysomal RNA (estimated to contain 5 μ g polyA-RNA), 45 units AMV reverse transcriptase and dCTP labelled to 4 Ci mmol⁻¹ with ³²P-dCTP (Amersham). Approximately 1.4 μ g cDNA was synthesised in 30 min. The reaction was stopped by the addition of EDTA (to 10 mM) and extracted with phenol, followed by ether, before being passed over a Sephadex G-50 fine column in 10 mM Tris, pH 7.4, 2 mM EDTA and, 10 mM NaCl (TEN). The void volume was collected and precipitated with ethanol. After centrifugation, the RNA was hydrolysed with NaOH (ref. 31), neutralised and precipitated with ethanol. The cDNA was then used as template for the synthesis of the second strand by *E. coli* DNA polymerase I essentially as described³¹. The reaction took place at 42 °C for 10 min in 100 μ l using 1.1 μ g cDNA, 10 units DNA polymerase I, and 200 μ M of each deoxynucleotide triphosphate with dCTP adjusted to 30 Ci mmol⁻¹ as above. Approximately 0.85 μ g of the second strand was synthesised. The reaction was stopped and extracted as above before being passed over a Sephadex G-50 fine column in TEN containing only 0.1 mM EDTA. Column fractions containing the ds cDNA were then treated with *Aspergillus oryzae* S₁ nuclease as described elsewhere³¹. After extraction and precipitation with ethanol, approximately 1.0 μ g ds cDNA was obtained. Aliquots of *a*, first strand product; *b*, first strand product after base treatment; *c*, second strand product and *d*, second strand product after S₁ nuclease treatment were examined on a 1.5% agarose gel in alkaline conditions as described³². Terminal addition of dCTP to the ds cDNA by terminal deoxynucleotidyl transferase (TdT), prepared as described elsewhere³³ was carried out by a modification³⁴ of the Co²⁺ procedure³⁵. The reaction was carried out in 500 μ l containing 140 mM cacodylic acid, 30 mM Tris base, 110 mM KOH (final pH 7.6), 0.1 mM dithiothreitol, 150 μ M dCTP (adjusted to 8 Ci mmol⁻¹ with ³H-dCTP (Amersham)), 1 mM CoCl₂ (added to prewarmed reaction mix before enzyme addition), approximately 1.0 μ g ds cDNA (assuming an average MW giving approximately 600 base pairs, this provides 10 pM 3' termini per ml) and 0.5 μ l TdT (2.3 $\times$ 10⁵ units ml⁻¹). The reaction was allowed to proceed at 37 °C for 10 min before being cooled and sampled to determine incorporation. Approximately 30 dC residues were added per 3' terminus. The reaction was stopped, extracted, desalted and precipitated with ethanol as above. Aliquots of *e*, second strand product; *f*, second strand product after S₁ nuclease treatment, and *g*, dC-tailed ds cDNA were analysed on a 1.7% agarose gel in Tris-acetate-NaCl (ref. 36). The dC-tailed ds cDNA was then preparatively electrophoresed on a similar gel and the '1,500-base pair' region (arrow) cut out of the gel and electrophoretically eluted into a dialysis bag as described elsewhere³⁷. The eluted material was extracted as above, concentrated by lyophilisation and precipitated with ethanol. After centrifugation, the 1,500-base pair dC-tailed ds cDNA (approximately 80 ng) was redissolved in 10 mM Tris HCl, pH 7.4, 0.25 mM EDTA and 100 mM NaCl (annealing buffer). pBR322 plasmid DNA, isolated as described elsewhere³⁸ was digested with a 1.5-fold excess of *Pst*I endonuclease in conditions suggested by the vendor (New England Biolabs) and the linear plasmid DNA was cut out and eluted from a 0.7% agarose gel in TBE³⁹ as described above. The plasmid DNA was 'tailed' with dG residues using procedures similar to those described above. Approximately 15–20 dG residues were added per 3' terminus. Following extraction, the dG-tailed vector was passed over a Sephadex G-50 fine column in annealing buffer and the void volume was collected. Equimolar amounts of dC-tailed ds cDNA and dG-tailed vector DNA were allowed to anneal essentially as described by W. Rowe and R. A. Fratell (personal communication) except that the vector concentration was kept at 75 ng ml⁻¹ in the annealing reaction. Circularisation was monitored by electron microscopy¹⁶ and was typically about 20–40%. This annealed DNA was used directly for transformation into χ 1776 or χ 2282.

transformants were found to be capable of immediate growth in media containing at least 1,000 μ g ml⁻¹ of Tp, and were termed 'strong expressors'. Plasmid DNA isolated from these colonies was shown by repeat transformation to encode both the Tc and Tp resistance phenotypes. However, Tp^RTc^R transformants occurred in different experiments at only 20–60% of the frequency observed when selection of transformants was carried out for Tc resistance alone. Transfer of Tc-selected colonies on to minimal medium agar plates containing Tp showed that all such clones express resistance to at least 1,000 μ g ml⁻¹. Together, these findings suggest that phenotypic expression of Tp resistance may be delayed in transformants until a sufficient quantity of plasmid-specified DHFR has accumulated. Analogous results have been obtained with other antimicrobial drug-resistance determinants encoded by plasmids introduced into *E. coli* by transformation²⁰.

Structure of the DHFR cDNA

Gel electrophoresis of endonuclease-cleaved plasmid DNA from three separately derived bacterial clones that expressed high levels of trimethoprim resistance showed similar overall patterns. Using such data, a cleavage map (Fig. 4) of the cDNA insert of one of these (pDHFR7) was constructed.

Examination of the amino acid sequence of the mouse DHFR enzyme²¹ allowed us to assign one of the *Hae*III cleavage sites to the *trp-pro* (TGG-CCX) present at amino acid positions 24 and 25, thus localising the DHFR structural sequence to a position near the 5' end of the mRNA template used in synthesising the cloned cDNA. Other cleavage sites within the DHFR structural sequence were consistent with positions predicted by computer analysis of the amino acid sequence. DNA sequence analysis of two separate regions of the cDNA provided direct verification that the nucleotide sequence of the insert corresponds to the amino acid sequence reported for the mouse DHFR enzyme, and also confirmed that the coding sequence for DHFR is located at the ds cDNA equivalent of the 5' end of the mRNA.

The nucleotide sequence at the pBR322-cDNA junction nearest the 5' end of the mRNA used as template for DHFR cDNA (that is, at the *Pst*I₀ site) is of special interest. The complement of the 'sense' strand of β -lactamase gene of the vector (J. G. Sutcliffe, personal communication) is interrupted at the *Pst*I site by a series of 11 dG residues added by the terminal transferase, and these are followed immediately by (1) an ATG (AUG) protein start codon, and (2) the codon for the first amino acid of the mouse DHFR structural gene. The sequence that codes for the mouse DHFR is in the same orientation as that encoding the β -lactamase on the vector plasmid; however, the

number of incremental G residues (that is, 10) at the vector-insert junction ensures that the DHFR cDNA sequence is not in the same translational reading frame as the β -lactamase gene.

If the phenotypic expression we have observed for the mouse DHFR sequences in bacteria is the result of translational readthrough from signals that initiate protein chains within the β -lactamase gene, then the host bacterial cell must be able to circumvent the observed frame shift by a 'slippage' mechanism of translation. Such an event might potentially be aided by the long run of dG residues introduced at the pBR322-cDNA junction and could account for our observation (Table 1) that plasmids containing a DHFR cDNA insert yield more than twice as many expressors as would be expected from considerations of reading frame and orientation. However, the high level of functional expression observed for both primary and secondarily transformed clones of pDHFR7 does not seem to be readily explained by slippage of tRNA molecules during translation.

Perhaps a more likely explanation is that the *Pst*I-polyG-ATG sequence that has been constructed preceding the coding sequence for DHFR serves as a binding and protein initiation site for the bacterial ribosome. Recent studies^{22,23} have identified sequences on mRNA in the 5' direction from the initiator codon that are complementary to the CCUCC sequence at the 3' end of the 16S ribosomal RNA species, proposed by Shine and Dalgarno²⁴ to be involved in the binding of mRNA to ribosomes. It is tempting to speculate that the mRNA transcript from the sequence at the pBR322-cDNA

junction has sufficient complementarity to the CCUCC sequence to allow ribosomal binding when a translational start signal is located an appropriate distance away. In such an event, the ATG protein start signal that immediately precedes the coding sequence for the mouse DHFR might initiate a peptide chain having a size characteristic of the mammalian enzyme. Immunological analysis of extracts derived from pDHFR7 and other expressing clones has yielded results consistent with this interpretation (see below).

Analysis of enzyme activity encoded by pDHFR7 plasmid

Mammalian dihydrofolate reductases can be distinguished from their bacterial counterparts by the ability of mammalian enzymes to use folate as a substrate and by their differential sensitivity to competitive inhibitors^{25,26}. In initial experiments, the reduction of folate to tetrahydrofolate was measured using extracts from the pDHFR7 clone, from a Tp-sensitive clone containing a DHFR cDNA insert (the pDHFR10 plasmid), and from cells that contain only the pBR322 vector. Although all three clones are capable of synthesising a chromosomally produced bacterial enzyme, only the enzyme present in extracts from cells containing the pDHFR7 plasmid gave reduction of folate ($4 \times$ background). Additional evidence that the reductase encoded by the pDHFR7 plasmid is of mammalian origin was obtained by inhibitor analysis (Fig. 5). The DHFR isolated directly from mouse cells and the activity encoded by the pDHFR7 plasmid showed identical sensitivities to methotrexate, trimethoprim and a triazine derivative (2,4,-diamino-1-(4'-butylphenol)-6,6 dimethyl-1, 6-dihydro-1,3,5-triazine); both enzyme activities were 200 times more sensitive to the triazine than to trimethoprim. In contrast, bacterial dihydrofolate reductase is inhibited more effectively by trimethoprim ($K_i = 5 \times 10^{-9}$) than it is by triazine ($K_i = 6.5 \times 10^{-4}$)²⁵.

As methotrexate binds stoichiometrically to dihydrofolate reductase²⁷, we can estimate the number of molecules of enzyme in the pDHFR7 plasmid extracts from the methotrexate inhibition data of Fig. 5. We calculate from the specific activity of the extract (3 units per mg of soluble protein) and the specific activity and methotrexate binding parameters of the mouse enzyme²⁸ that 0.01% of the soluble bacterial protein is active mammalian DHFR.

Immunological characterisation of bacterial cell extracts containing mouse DHFR

Immunological evidence confirming the nature of the DHFR encoded by pDHFR7 and other plasmids that contain a mouse DHFR cDNA insert was obtained using a solid-phase sandwich radioimmunoassay¹². Tp^R clones of χ 2282 containing the independently derived plasmids pDHFR 7, 12 and 13 showed a strong reaction with rabbit antibody directed against mouse DHFR in an *in situ* immunoassay¹² (data not shown); protein that reacted with the antibody was also made by bacteria which showed low levels of phenotypic expression and by some clones that did not make a biologically functional DHFR (that is, were Tp sensitive). The nature of the antigen synthesised by Tp^S and Tp^R clones was examined more fully using a newly developed method (filter affinity transfer, or FAT procedure) for the *in situ* immunological characterisation of proteins in gels²⁹. This procedure depends on the covalent coupling of F(ab)₂ antibody fragments to a chemically derivatised and activated cellulose filter; antigen transferred on to the filter from an SDS-polyacrylamide gel is detected by subsequent incubations with antiserum and ¹²⁵I-labelled *Staphylococcus aureus* protein A (ref. 12).

Filter affinity transfer analysis of the pDHFR7 extract (Fig. 6, lanes b, c) shows the presence of protein that reacts immunologically with the antibody to mouse DHFR and further shows

Fig. 3 Detection of colonies containing DHFR cDNA inserts by *in situ* hybridisation. Colonies were screened for DHFR sequences using a modification (G. N. Duell, unpublished) of an *in situ* hybridisation procedure¹¹. Tc-resistant colonies were transferred to nitrocellulose filters (Millipore, HAWG) that had been placed on Penassay broth agar plates containing Tc (10 μ g per ml). (Filters had been washed twice by boiling in H₂O and autoclaved before being placed on plates.) After 2–3 d of bacterial growth at 32°C, the filter was removed from the plate and placed on a Whatman no. 3 pad saturated with 0.5 M NaOH. After 7 min, the filter was sequentially transferred to a series of similar pads saturated with 1 M Tris, pH 7.4 (twice, 7 min each); 1.5 M NaCl, 0.5 M Tris, pH 7.5 (once, 7 min); and 0.30 M NaCl, 0.03 M Na citrate (2 $\times$ SSC) (once, 7 min). After the excess liquid had been removed by suction, the filter was placed on a pad containing 90% ethanol, dried by suction and baked *in vacuo* at 80°C for 2 h. Before hybridisation, filters were pretreated for 3–6 h at 65°C in hybridisation buffer that contained 5 $\times$ SSC, pH 6.1 0.2% SDS, 0.02% Ficoll 400 (Pharmacia) and 8 μ g ml⁻¹ *E. coli* tRNA. Hybridisations were carried out with individual filters in 1.5 ml hybridisation buffer containing 2 $\times$ 10⁴ c.p.m. ³²P-labelled purified DHFR cDNA¹³ in a sealed plastic bag at 65°C for 24 h. The filters were then washed in hybridisation buffer (once, 60 min at 65°C); in 5 $\times$ SSC, pH 6.1 (three times, 60 min each at 65°C); and in 2 $\times$ SSC, pH 7.4 (twice, 10 min at room temperature), air dried, and prepared for autoradiography. Left: top, a collection of χ 1776 colonies which contain a DHFR cDNA insert; middle, Tc-resistant χ 2282 colonies derived from transformation with annealed pBR322 ds cDNA—both reacting and non-reacting colonies are seen; bottom, colonies containing pBR322 and pACYC101 plasmids which show no visible hybridisation. Right: several positive colonies on a representative filter analysed in screening χ 1176 transformants. Negative colonies represent clones containing pBR322 or pACYC101 plasmids which show no visible hybridisation.

Fig. 4 Map of cDNA insert and adjacent regions of pDHFR 7 plasmid. Endonuclease cleavage map and partial DNA sequence of cDNA insert of the pDHFR 7 plasmid. The shaded area indicates the structural sequence for mouse DHFR. The locations of endonuclease cleavage sites were determined from polyacrylamide gel electrophoresis patterns following simultaneous or sequential digestions of either intact pDHFR or fragments isolated after earlier digestions. Restriction endonucleases (New England Biolabs or Bethesda Research Laboratories) were used according to the vendor's recommendations. Cleavage sites listed above the shaded area were assigned to specific amino acid positions within the mouse enzyme by nucleotide sequence. The boxed numbers of the *HpaII* and *PstI* sites indicate the locations of the sites in the pBR322 plasmid as determined by Sutchiff (personal communication), and were used in orientating the amino acid sequence of the DHFR gene with respect to the β -lactamase sequence. The nucleotide sequence in the vicinity of the pBR322-cDNA junction corresponding to the 5' end of the mRNA used as template for the cDNA, and the sequence in the region of the *HpaII* site at amino acid 104 of the structural sequence are shown. Nucleotides and amino acids are numbered from the start of the DHFR coding sequence; nucleotides in the 5' direction on the mRNA from position 1 have negative numbers. The DNA sequence shown were determined by the method of Maxam and Gilbert⁴⁰. Fragments (*d* + *c*) and (*a* + *b*) were 5' end-labelled at the *HpaII* and *BglII*-generated ends, treated with *HaeIII* endonuclease, and subjected to electrophoresis in 6% acrylamide gel and TBE buffer³⁹. Fragments *a*, *b* and *c* were eluted from the gel³², precipitated with ethanol and used directly for base sequence determination using the gel system described in refs 40 and 41.

that most of the immunologically reactive material has the same electrophoretic mobility as enzyme obtained directly from mouse cells (molecular weight 22,000) (Fig. 6, lane *a*). An immunologically reactive band that migrates at this position was also seen in the material eluted with folic acid from a methotrexate affinity column that contained an extract from χ 2282 (pDHFR7) cells (Fig. 6, lane *d*), suggesting that the 22,000 MW protein made by these bacterial cells has binding sites for both methotrexate and folate. Additional immunologically reactive bands which have mobilities consistent with a MW of 30,000–90,000 were seen in varying amounts in different extracts of bacterial cells that contained pDHFR7 (Fig. 6, lanes *b*, *c*); as the 1,500-base pair insert in this plasmid is capable of coding for a polypeptide no larger than 50,000 MW, we conclude that the most slowly moving bands are likely to be hybrid proteins that include antigenic sites of the mouse DHFR. Immunologically reactive high MW proteins are also made by a *Trp*⁸ clone (pDHFR21, Fig. 6, lane *e*) which contains a DHFR cDNA insert; however, this clone fails to synthesise an immunologically reactive 22,000 MW band. No immunological reactivity with

antibody made to mouse DHFR was detected in extracts of cells carrying only the pBR322 vector (Fig. 6, lane *f*).

Variation in level of expression of mouse DHFR cDNA sequences in bacteria

Thirty-two separately derived clones of χ 2282 transformants that had been selected on plates containing only Tc were replated on medium containing both Tc and Tp, and also were tested for the presence of a DHFR cDNA insert by *in situ* hybridisation. Fourteen colonies contained sequences homologous with the purified DHFR cDNA probe, and five of these (termed 'weak expressors') grew on plates containing 5 μ g ml⁻¹ or more Tp. The remaining nine clones that contained DHFR sequences failed to show any growth on concentrations of Tp above 2.5 μ g ml⁻¹, and were termed 'non-expressors'. Plasmid DNA isolated from four of the nine non-expressors and from all five weak expressors was analysed by gel electrophoresis, and the mean inhibitory concentration (MIC) of Tp was determined for each of the clones. The structural relationship of the cDNA

Fig. 5 Inhibitor analysis of DHFR from bacterial cells. Stationary phase cultures of χ 2282 expressing trimethoprim resistance were grown in the presence of Tp ($1 \mu\text{g ml}^{-1}$) in minimal medium, washed with isotonic saline, and suspended in 50 mM potassium phosphate buffer, pH 7.0, containing 10 mM benzamidine and 10 mM phenyl methyl sulphonyl fluoride (3 volumes buffer to 1 volume cells). The suspension was sonicated and centrifuged at 10,000 r.p.m. for 15 min. The supernatant was centrifuged for 1 h at 100,000g before being studied. An R_2 methotrexate-resistant mouse cell extract was prepared as described elsewhere⁴². Enzyme activity was measured by the radioactive folic acid assay previously described²⁸. Protein was determined by the method of Lowry⁴³. Approximately 3 units of activity from the χ 2282 extract or 5 units from the methotrexate-resistant mouse cell extract were incubated with inhibitor for 10 min at 24°C before assaying for folate reductase activity; the concentrations shown represent the final concentration of inhibitor in the reaction mixture. Background values, determined by measuring enzyme activity in the presence of 10 mM methotrexate, have been subtracted from all points. The results presented are the average of duplicate samples which generally varied by less than 10% and are expressed as a percentage of the value obtained in the absence of inhibitor. One unit of activity is the amount of enzyme needed to reduce 1 nmol of folate in 15 min at 37°C. Δ and $\blacktriangle$ indicate addition of methotrexate, $\circ$ and $\bullet$ indicate addition of the triazine derivative, and $\square$ and $\blacksquare$ indicate trimethoprim addition for χ 2282 and the mouse cell extracts, respectively.

insert to the β -lactamase gene sequence of the vector, the length of each insert, and the minimal inhibitory concentration (MIC) determined for the clone are shown in Fig. 7. As can be seen, plasmids pDHFR7, 12, 13 and 26–29 all contain a complete DHFR structural sequence inserted in the same orientation (that is, orientation a) as the gene encoding the bacterial β -lactamase. The clone carrying each of these plasmids expresses Tp resistance, although the MIC varies from $150 \mu\text{g ml}^{-1}$ for pDHFR28 to $>1,000 \mu\text{g ml}^{-1}$ for pDHFR7, 12 and 13; the greatest reactivity with antibody to mouse DHFR occurs with pDHFR12 (unpublished data).

It is unlikely that translational reading frame is the determining factor in the different levels of expression observed in these clones, as our DNA sequence analysis indicates that a correct reading frame is not essential for efficient expression in pDHFR 7, 12 or 13. However, the positioning of the putative ribosomal binding site in relation to the ATG start codon may potentially influence the strength of expression by affecting the formation of the translational initiation complex (compare with ref. 23) (Figs 4, 7).

The end of DHFR structural sequence that corresponds to the 5' end of the mRNA is not present in plasmids pDHFR 21 and 24, thus explaining the observed lack of functional expression of the cDNA in these clones. However, pDHFR21, which has lost less than 15% of the structural sequence, nevertheless encodes a (probably hybrid) peptide that contains antigenic sites which

react with antibody to mouse DHFR (Fig. 6 and unpublished data). It is particularly interesting that the clone carrying pDHFR25 expresses a low level of Tp resistance, although the coding sequence for the DHFR enzyme is inserted in an orientation opposite to that of the β -lactamase gene. This finding, and our detection in extracts of the pDHFR25 clone of protein that reacts immunologically with antibody to the mouse enzyme (unpublished data), suggest that readthrough transcription into the DHFR coding sequence from a promoter sequence located on or near the distal segment of the β -lactamase gene may occur. Consistent with this interpretation are preliminary data suggesting that DHFR antigenic sites are also synthesised by cells carrying pDHFR23, which is a non-expressor of Tp resistance and contains a cDNA insert in orientation b (Fig. 7). Further study is required to determine whether sequences in the distal segment of the β -lactamase gene are capable of serving as weak promoters for the initiation of mRNA chains that extend into the DHFR cDNA.

The findings reported here indicate that the bacterial clones we have constructed are synthesising and phenotypically expressing DHFR encoded by mouse cDNA sequences: (1) the cDNA insert cloned in bacteria has been shown by *in situ* hybridisation to be homologous with the mouse gene and by direct DNA sequence analysis to encode the amino acid sequence of mouse DHFR, (2) DHFR enzymatic activity and resistance to Tp are specified by nucleotide sequences present on chimaeric plasmids but not on the vector, (3) the DHFR

Fig. 6 Filter affinity transfer analysis²⁹ of bacterial cell extracts. 20 μl of extracts in SDS sample buffer were run at constant current for 3 h in an 11.25% SDS-polyacrylamide slab gel. The gel was incubated in PBS (50 mM phosphate buffer containing 0.15 M NaCl) for 30 min and placed on a blotter wet with PBS. Peptides were specifically transferred from the gel to strips of a dry cellulose filter that had been covalently coupled to anti-DHFR F(ab)₂ fragments¹². Filters were washed, incubated with antibody to DHFR, washed again and treated with ¹²⁵I-labelled protein A. After additional washing and drying steps, the filters were analysed by autoradiography. The eluate fraction (lane d) was obtained by passage of an extract of χ 2282 cells containing pDHFR7 over a 0.5 ml methotrexate-Sepharose affinity column. The extract was acidified to pH 5.8, passed over the column and the bound fraction was eluted with 2 mM folic acid in a 5 mM NaHCO₃ buffer at pH 8.5 as described elsewhere²⁸. Lane a, extracts of mouse cell line; lanes b and c, pDHFR 7; lane d, eluate from methotrexate column; lane e, pDHFR21; lane f, pBR322.

Fig. 7. Some structural and functional properties of chimaeric plasmids and χ 2282 clones containing DHFR cDNA insert. The MIC of Tp for each of the χ clones was tested on M9 minimal agar plates containing biotin ($2 \mu\text{g ml}^{-1}$), casamino acids (0.5%), DA_2 ($50 \mu\text{g ml}^{-1}$) and Tp concentrations ranging from 0 to $1,000 \mu\text{g ml}^{-1}$. χ 2282 (pBR322) was used as a control and is sensitive to Tp at $2.5 \mu\text{g ml}^{-1}$, as determined by incubation at 32°C for 3 d. Plasmid DNA isolated from each clone was digested with *Pst*I endonuclease¹⁵ at 37°C for 3 h and extracted sequentially with phenol and ether. DNA was precipitated with ethanol, resuspended in $8 \mu\text{l}$ TE buffer and electrophoresed in 1.2% agarose gels in TBE buffer to determine the length of the inserted fragment. ColEI plasmid DNA digested with *Hae*II endonuclease⁴² was added to each sample as an internal molecular weight standard. Additionally, *Hind*III-generated fragments of SV40 DNA were used as an external standard⁴⁵. The standard error is ± 100 base pairs with the method used. The orientation of the cDNA inserts in the vector plasmid was determined by gel analysis of plasmid DNA digested with *Bgl*II and *Hinc*II endonucleases; in addition, pDHFR25 was treated with the *Eco*RI and *Bgl*II enzymes to confirm the orientation of its insert. The direction of transcription of the β -lactamase gene of pBR322 is indicated by an arrow. The shaded area in each plasmid map indicates the structural sequence for DHFR. The numbers shown above each *Pst*I site indicate the distance (in base pairs) between the cleavage point and the first nucleotide of the DHFR structural sequence as described in Fig. 4. This distance was determined exactly by DNA sequence analysis for plasmids pDHFR 7, 12 and 13 and was estimated for the other plasmids by gel electrophoresis of fragments produced by either the *Hae*III or *Hpa*II endonucleases. For the chimaeric plasmids that we subsequently sequenced, this estimate proved to be accurate within 5 base pairs. *Pst*I–*Bgl*II distances were determined for the chimaeric plasmids by gel electrophoresis using *Hpa*II-cleaved pBR322 DNA as an internal standard. Nucleotides in the 5' direction on the mRNA from position 1 have negative numbers and are estimates obtained from gel analysis for all plasmids except pDHFR7 and 12.

encoded by the constructed plasmids shows differential sensitivity to competitive inhibitors of DHFR characteristic of the mammalian gene product, and (4) the enzyme synthesised by bacteria containing DHFR cDNA is immunologically reactive with antibody made against mouse DHFR.

Note that the clones which express the highest levels of Tc resistance contain an immunologically reactive peptide having a size characteristic of the mammalian DHFR. A peptide of this size could potentially result from proteolytic cleavage of a fused β -lactamase–DHFR protein that was initiated at the β -lactamase ribosomal binding site. This proposal is consistent with the finding of large-sized protein species containing DHFR antigenic sites in extracts from cells that are either Tp^R or Tp^S (Fig. 6). More intriguing, however, is the possibility noted above that the *Pst*I–poly dG sequence constructed at the vector–cDNA junction can act together with the nearby ATG (AUG) translational start codon to bind mRNA to the bacterial ribosome and initiate DHFR peptide chains within the cDNA insert. If this interpretation is correct, initiation of peptide chains within other eukaryotic cDNA inserts may be obtainable in bacteria by use of the same structural relationships that have resulted in expression of the mouse DHFR coding sequence. Additional DNA

sequence analysis and investigation of the protein products encoded by chimaeric plasmids should provide definitive information on this point and should help elucidate further the structural basis for the different levels of Tp resistance expressed by various clones.

Some of the bacterial clones we have isolated produce proteins that react immunologically with antibody to mouse DHFR but which are not biologically active. Our results suggest that an important obstacle to functional expression of mammalian DNA sequences in bacteria has been the development of an assay capable of detecting those clones that possess both a complete coding sequence and the correct nucleotide relationships to allow such expression. The strong phenotypic selection possible in the present experiments has provided an effective means of identifying and isolating expressing clones.

As the cloned coding sequence for mouse DHFR is selectable in higher organisms as well as in bacteria, it constitutes a powerful tool for the construction of eukaryotic cloning vectors, for the isolation of replication regions of eukaryotic chromosomal and extrachromosomal genomes (compare ref. 30), and for the isolation and characterisation of signals that control genetic transcription and translation in variety of species.

letters to nature

N Galaxies—a new class of X-ray sources

BURBIDGE¹, classified extragalactic objects with bright nuclei into three classes: in order of increasing optical luminosity these are (1) Seyfert galaxies; (2) N galaxies; (3) quasars. Many Seyferts and several quasars have been shown to be X-ray sources. Here we show that N galaxies are also powerful X-ray sources. In fact, all six N galaxies in the 3C radio catalogue with redshifts less than 0.06 (ref. 2) are detected by the first full-sky survey of the Goddard Space Flight Center detectors (A2) on HEAO 1. X-ray emission has also been discovered from a strong Southern Hemisphere radio source, the N galaxy Pic A. Six of the seven objects are classified as broad-line radio galaxies (BLRGs)^{3–5} and one (3C371) is classified as a BL Lac object⁶. These objects are differentiated from the newly discovered class of 'emission line' galaxies⁷ by their high radio flux and extremely broad lines. Before HEAO 1 there was one confirmed N galaxy, 3C120 (ref. 8), and one suggested, 3C390.3 (refs 9, 10). We detect 3C120, strengthen the identification of 3C390.3, and present evidence for X-ray emission from four new sources, 3C111, 3C382, 3C371, and Pic A. We also suggest 3C445 as the identification of 2A2220-022 (ref. 11).

Figure 1 shows 90% confidence error boxes on the positions of these seven galaxies together with 4U (ref. 10) or 2A (ref. 11) error boxes where applicable. The 2–10 keV luminosity of these objects, as well as other relevant information, is given in Table 1. We have also looked for X-ray flux from the next closest N galaxies, PKS0521–36 and 3C227. No significant flux was seen, but the 90% upper limit on the X-ray luminosities (given in Table 2) are consistent with their luminosities being comparable to the seven detected N galaxies. Except for quasars, these N

galaxies are the most luminous class of compact X-ray sources yet detected.

Grandi and Osterbrock have classified radio galaxies spectroscopically as BLRG or narrow-line radio galaxies (NLRG) and have demonstrated a high degree of association between the classification 'broad-line' and the morphological type 'N'. In marked contrast to the situation for BLRGs, only 3C405 (Cyg A) of the five NLRGs listed by Grandi and Osterbrock, with redshifts less than 0.06, is a detected X-ray source. 3C317 is confused with Ab2052, a distance class 3 cluster, and so its luminosity is poorly determined. Upper limits on the flux from the other three NLRGs are given in Table 2. The deduced upper limits on the luminosities are considerably less than average X-ray luminosities for BLRG of $\sim 3 \times 10^{44}$ erg s⁻¹. Note that of the detected N galaxies, the one with the narrowest emission lines, 3C371, has the smallest X-ray luminosity.

The lack of X-ray emission from NLRGs contrasted to the virtual certainty of X-ray emission from BLRGs is similar to the distinction between type 1 and type 2 Seyferts, that is, none of the ~20 known X-ray emitting Seyfert galaxies are classical type 2 Seyferts. Grandi and Osterbrock have drawn attention to the optical spectral similarities and differences between BLRGs and type 1 Seyferts, and NLRGs and type 2 Seyferts, respectively.

The fact that many of these N galaxies possess compact radio components suggests that the synchrotron self-Compton process (SSC)¹² may be the principle cause of the X-ray emission. For 3C390.3, the best studied of these objects, a SSC model predicts a physical size to the X-ray emitting region of ~0.1 pc and a time scale for X-ray variability of months¹³. The detection of 3C390.3 by Uhuru and Copernicus at considerably higher flux levels and an Ariel 5 upper limit on 3C382 (ref. 14) ~20% lower than the present detection indicate possible variability in

Table 1 Positive detection of N galaxies

* Luminosity converted assuming all spectra are like that of 3C390.3 and $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$. Statistical errors are $\sim 20\%$ for weakest source.

this class of object. However, results from the second complete HEAO 1 sky scan will provide a better test of variability in these objects because of the difficulty in comparing the fluxes of these weak sources between different satellite experiments. Preliminary analysis of data from the first HEAO 1 survey indicates no variability ($\pm 50\%$) for these sources on a day-to-day basis.

Alternatively, Fabian¹⁵ has suggested that the X rays are produced by gas clouds colliding with velocities of the order of the Doppler width of the broad lines. This would account for the strong selection seen between BLRGs and NLRGs and the hard spectrum seen in these objects. (Detailed spectral analyses are in progress and will be reported elsewhere.) Only simultaneous radio and X-ray observations similar to that already performed for Cen-A¹⁶ can distinguish between these two mechanisms.

Further HEAO 1 observations will provide the opportunity to determine the detailed spectra of these objects and their variability on a time scale of months. Also, further BLRGs, when they are discovered optically, may be identified with some of the ~ 20 new¹⁷, weak, unidentified sources discovered with the HEAO 1 A2 experiment.

Table 2 90% Confidence upper limits

Name	Z	L_x (90%)	Notes
3C98	0.0306	$<0.5 \times 10^{44}$	NLRG

Fig. 1 HEAO 1 A-2 90% confidence error boxes. Other error boxes indicated where applicable. The asterisks indicate the candidate object. The dashed lines indicate 90% confidence error boxes under the assumption that the source intensity did not vary during the observation. In the case of 3C371 there is an additional new source H1800+69 indicated. On H220-02 the smaller box is 2A220-022.

The solar wind
at the turn of the century

GEOMAGNETIC ACTIVITY is driven by the solar wind, so information on the past history of the wind can be derived from studies of geomagnetic indices¹⁻³. Comparison of geomagnetic activity and sunspot number over the past hundred years shows that although both vary with the 11-yr solar cycle, they do so with characteristically different patterns. Geomagnetic activity rises and falls with about the same amplitude over each 11-yr solar cycle, but these variations seem to be superposed on a longer-term cycle of similar amplitude. Consequently there is a long-term variation in the 11-yr cycle minima as well as maxima. In contrast, in the sunspot number record the long cycle appears as changing amplitudes of the 11-yr cycles, with sunspot number returning to near zero at each 11-yr minimum. As geomagnetic activity reflects solar wind conditions, it is possible to extrapolate backwards in time the present-day solar wind measurements taken near the long-cycle maximum and we estimate here that around 1900, near the long-cycle minimum, either the average solar wind speed was as much as a factor of two lower, or the average southward component of the solar wind field was as much as a factor of three smaller, or both parameters were significantly less than at present. Thus, in the not too distant past the solar energy output by means of the solar wind was different from what it is now.

That the solar cycle variations of sunspot number and geomagnetic or auroral activity are different has been known for some time. Fritz⁴ first noted that the auroral cycle lags the sunspot cycle. More recently, spectral analyses of the magnetic activity index A_p and sunspot number show that both series have the same strong line at 10.2 yr and that the lag noted by Fritz is of 18 months duration⁵. The shapes of the two solar-cycle variations are also different. Magnetic activity tends to have a secondary, post-sunspot-maximum peak which is associated with recurrent storms⁶.

The difference between geomagnetic activity and sunspot number that we discuss here concerns the pattern of the minima from cycle to cycle. Figure 1 shows the solar-cycle variations of yearly averages of sunspot number and aa index of geomagnetic activity in the top and middle panels, respectively, for those cycles from the 1900s to the 1960s where the $\langle aa \rangle$ minima

Fig. 2 Solar cycle minima of yearly means of aa . Points between dashed lines increase almost linearly.

increase almost linearly in time. The total increase is about 10 units, an amount typical of the change in $\langle aa \rangle$ over a single solar cycle. The slope of the increase is so steep that $\langle aa \rangle$ at the 1910 maximum is about the same as $\langle aa \rangle$ at the 1954 minimum. In striking contrast is the behaviour of the average sunspot variation. Over the same period the maxima increase by about 120 units; but at each solar minimum the sunspot number returns to near zero.

The increase in sunspot maxima is part of the well-known '80-yr' sunspot cycle, and apparently the rise in the $\langle aa \rangle$ minima is the geomagnetic activity or solar wind manifestation of this same cycle. Brown⁷ has recently shown that although the sunspot number falls to very low values at minima, the 80-yr cycle is also clearly present in the time variation of the minima. In addition, he found that the phase difference between the variations of the minima and the maxima is such that the level of any given minimum is a good predictor of the level of the subsequent maximum.

Figure 2 shows the minima of $\langle aa \rangle$ as a function of time. A root mean least squares fit to the six points between 1900 and 1960 is given by

$$\langle aa \rangle_{\min} = 0.22 (T - 1900) + 5.70 \tag{1}$$

with a correlation coefficient of 0.99. The variation of these six points is remarkably linear. The possibility that the linear increase is caused by a systematic error in $\langle aa \rangle$ owing to some change occurring at one of the two stations used to determine the daily aa can quickly be ruled out because almost identical increases occur at the two antipodal stations (Melbourne and Greenwich) used to derive the index. The linear increase is apparently the result of a change in the driver of geomagnetic activity—the solar wind.

Because in the case of geomagnetic activity the 11-yr cycle appears to be superposed on or added to the long-term cycle, the pattern of the 11-yr cycle can be separated from the long-term cycle by defining a quantity $\langle aa \rangle_{\text{residual}}$ given by

$$\langle aa \rangle_{\text{residual}} = \langle aa \rangle_{\text{measured}} - \langle aa \rangle_{\min} \tag{2}$$

where $\langle aa \rangle_{\min}$ is defined by equation (1). The values of $\langle aa \rangle_{\text{residual}}$ are shown in the lower panel of Fig. 1. The important point to note is that the amplitudes of the cyclic changes are all about the same. The residual $\langle aa \rangle$ averaged over each cycle varies only from a high of 7.2 for the 1910s to a low of 5.8 for the cycle beginning in 1924. The shapes of the solar cycle variations of residual $\langle aa \rangle$ are almost square. Post-sunspot-maximum activity peaks are clearly present but less pronounced relative to the first peak in each cycle as compared to the solar cycle variations of $\langle aa \rangle$ in the middle panel. The first peak does not necessarily occur at sunspot maximum, but, on the average, precedes maximum. In the two solar cycles preceding those shown in Fig. 1, the first peaks are well pronounced and also occur before sunspot maximum (see Fig. 4 of Mayaud⁸). Note that these findings are not consistent with the usual association of first peaks with flare-induced geomagnetic storms, which are expected to occur most frequently at sunspot maximum.

Fig. 1 Yearly means of sunspot number, the aa index, and residual aa during the rising years of the long cycle.

Following the suggestion of Hirshberg⁹ that the 11-yr geomagnetic activity cycle, which is so different from the sunspot cycle, may well represent an 11-yr cycle of the solar wind, N.U.C. *et al.*¹⁰ found a remarkable similarity between the variations of geomagnetic activity and solar wind speed over the past solar cycle. To provide good correlations on both short and long time scales, they derive an empirical relationship between geomagnetic activity and the product of the square of the solar wind speed V and the southward component of the interplanetary magnetic field B_s . With a relationship of this kind we can estimate what the solar wind speed and/or magnetic field intensity may have been in 1901.

The regression line of $\langle aa \rangle$ on $\langle B_s \rangle \langle V^2 \rangle$ for data from the past solar cycle is

$$\langle aa \rangle = 1.3 + 4.7 \times 10^{-5} \langle B_s \rangle \langle V^2 \rangle \quad (3)$$

where B_s is measured in units of nT and V in km s^{-1} . The correlation coefficient is 0.9. Equation (3) was used to draw the curves of constant $\langle B_s \rangle \langle V^2 \rangle$ in Fig. 3 for the maximum and

Fig. 3 Curves of constant $\langle B_s \rangle \langle V^2 \rangle$ for the values of $\langle aa \rangle$ listed in the right margin. Shaded area indicates ranges of yearly averages of observed values. Dashed lines extrapolate variables from the 1965 minimum to the 1901 minimum.

minimum $\langle aa \rangle$ for solar cycle 14 beginning in 1901, and for cycle 20 beginning in 1965. Cycle 20 occurs just after the peak in the long cycle, and cycle 14 occurs at the long-cycle minimum. Thus, the overlap in the areas covered by these two cycles in Fig. 3 is small. Cycle 19, with an $\langle aa \rangle$ maximum of 32.9 and minimum of 17.3, would give essentially no overlap; but cycle 20 is plotted in Fig. 3 because it begins the era of spacecraft measurements. The ranges of observed $\langle B_s \rangle$ and $\langle V \rangle$ are indicated by the shaded rectangle, and the encircled datum point marks the averages $\langle B_s \rangle = 1.82$ nT and $\langle V \rangle = 395$ km s^{-1} for the $\langle aa \rangle$ minimum year 1965. Note that the observed $\langle B_s \rangle$ for 1965 is not the lowest observed value, as indicated by the shaded region, which extends down to $\langle B_s \rangle = 1.53$ nT. This lowest value is an average from 1964, the year of sunspot minimum; its uncertainty is rather large, since only about one month of hourly averages are available from 1964.¹¹ Interestingly, if curves were drawn for the five $\langle aa \rangle$ minima recorded prior to 1933, none of them would intersect the shaded region of observed solar wind values.

If in one extreme we assume that the solar wind speed in 1901 was the same as during $\langle aa \rangle$ minimum of the recent cycle, it follows that the magnitude of $\langle B_s \rangle$ was about 0.65 nT, as indicated in Fig. 3 by the intersection of the dashed line at $\langle V \rangle = 395$ km s^{-1} and the 1901 curve. This value of $\langle B_s \rangle$ is about a factor of three smaller than $\langle B_s \rangle$ for the 1965 $\langle aa \rangle$ minimum.

As mentioned by Russell², a reduced southward component can result either from a reduction in the intensity of fluctuations relative to the field magnitude, since an undisturbed solar wind has no significant southward component in the solar equatorial plane, or, if that ratio is constant, from a reduction in the field magnitude. Thus if the ratio of the southward component to the field magnitude was the same in 1901 as at present, then the field magnitude may have decreased by as much as a factor of three.

In the other extreme, we can assume that the solar wind field remained constant, and the speed decreased to produce the 1901 $\langle aa \rangle$ minimum. If $\langle B_s \rangle$ remained at the 1965 value of 1.82 nT, then the dashed line at that value in Fig. 3 indicates that the solar wind speed average was 237 km s^{-1} in 1901. A more physically correct treatment of this extreme is to assume that the field magnitude at the Sun and the ratio of $\langle B_s \rangle$ to the field magnitude at 1 AU remained constant. In this case, the increase in field magnitude with decreasing speed at 1 AU must be taken into account. The resulting dashed curve in Fig. 3, which was plotted from Parker's¹² equations, indicates that under these assumptions $\langle V \rangle$ was as low as 180 km s^{-1} . This is indeed a low value for a yearly average in comparison to solar wind measurements of recent times, where hourly averages of ~ 200 km s^{-1} are rare. These values for speeds and field intensities are extremes, and it is more likely that both quantities changed over the 64-yr period.

Although photographs of the corona during eclipses at the turn of the century are available, the plates are not calibrated, so comparisons to the present day corona cannot be made. However, in this study we have shown that there were considerable changes in the solar wind over the past century. This implies some change in the state of the solar corona itself.

Power harmonic radiation enhancement during the sudden commencement of a magnetic storm

THE enhancements of power harmonic radiation that occurred at the same time as a sudden commencement of a geomagnetic storm (ssc) and with geomagnetic pulsations that followed the ssc are described and discussed here. The power harmonic radiation was detected by an ELF-VLF wave receiver with two loop antennas and a vertical whip at Riverton, while geomagnetic variations were observed by three induction

magnetometers distributed at Thompson (55.9° N, 97.4° W), Riverton (51.0° N, 97.0° W) and Star Lake (50.1° N, 95.2° W), Manitoba, Canada. The power harmonic enhancements are accounted for in terms of the geomagnetically induced telluric current that was possibly shunted through transformer neutrals and a transmission line of a power system, giving rise to a near saturation of the transformer core material. The important role which the enhanced power harmonics may have in stimulation of emissions in the magnetosphere is considered.

During a joint IMS campaign for aurora/ULF-VLF waves in Manitoba, Canada, from 10 to 24 September 1977, a magnetic storm broke out on 21 September with an ssc. A generally accepted concept of an ssc was first presented in 1933¹ which in terms of hydromagnetics is described as a rapid compression of the Earth's magnetosphere due to an abrupt increase in the solar wind kinetic pressure². This specific event is ssc* in type which is characterised by a prominent negative kick on the magnetic horizontal (N-S) component before the compressional (positive) increase. Induction magnetograms at three stations, Thompson, Riverton and Star Lake indicate that the negative kick (southwards deflection) started 24.45.00 UT simultaneously at all three stations. The negative phase lasted until 20.45.47 at Thompson, 20.45.33 at Riverton and 20.45.30 at Star Lake. Following the negative phase, the compressional increase (northwards deflection) of the horizontal component took place during the intervals 20.45.47–20.47.30 at Thompson, 20.45.33–20.46.25 at Riverton, and 20.45.30–20.46.17 at Star Lake as can be seen in the lower panel of Fig. 1. This positive phase was followed by damped oscillations. At Riverton, the damped oscillation took a period of approximately 2 min and continued until 20.53.00. The ssc* and the subsequent damped oscillations in the Earth's magnetic field gave rise to two effects on VLF emissions which were recorded at Riverton concurrently with the ULF magnetic observation using a receiver system for finding the arrival direction³.

One of the two effects concerns natural VLF chorus emissions. This effect is already known and has been explained in terms of increases in gyrofrequency of suprathermal electrons and in the anisotropy factor of their distribution in velocity space during the course of a magnetospheric compression⁴. Bandwidth broadening, increase in mean frequency and enhancement of band-integrated intensity—the changes characterising the ssc effect in chorus as seen in the spectrogram in the upper panel of Fig. 1—are reasonably well understood in terms of the changes in the two parameters mentioned above.

The second effect, which is the main one considered here, is

enhancement of harmonics in commercial electric power. As the spectrogram shows, the intensities of the power harmonics increased almost concurrently with the distinctive deviations on the induction magnetograms. The main harmonic components before the ssc were the 3rd (180 Hz) and the 9th (540 Hz), both being relatively weak. At the onset of the negative kick, even harmonics came out: the bands of the 6th (360 Hz) and 12th (720 Hz) harmonics were considerably intensified. The pre-existing bands, the 3rd and 9th harmonics, seem to have been enhanced also. It is interesting that the harmonics appeared at multiples of 180 Hz as if it were the fundamental frequency. This suggests that they were generated in a three-phase a.c. transmission system. These bands then gradually decreased in intensity towards 20.45.45. They were enhanced again in a time interval 20.45.50–20.46.45 during which the harmonics up to 18th (1,080 Hz) were excited. After this, their intensity was increased again and again, for example, from 20.47.00 to 20.47.12, from 20.47.25 to 20.48.33 and so forth as shown in Fig. 1.

The initiation of the first enhancement of the harmonics (especially 6th) coincided with the initiation of the negative kick at Riverton where the VLF recording was carried out, but their decay came out about 10 s behind the positive turn of the magnetic deflection. The second enhancement then began about 15 s behind the positive turn and continued until about 20 s behind its negative turn at Riverton. The third and the fourth enhancements also occurred 15–20 s behind the corresponding deflections of the horizontal component at Riverton.

The above facts strongly suggest that the harmonics were generated in a power system near the VLF observation site at Riverton due to the effects of the ssc. One possibility is that the ssc-induced electric field gave rise to an electric current in a circuit consisting of ground-transformer A–transmission line–transformer B–ground. The current intensity must have had a slow temporal variation with a time scale comparable to that of the magnetic field variations detected by the induction magnetometers. The current probably gave rise to a quasi-d.c. bias to the hysteresis loop of the core material of the transformers, with probable magnetisation to near saturation with resultant non-linear distortion of the current waveforms⁵. Quasi-d.c. electric currents between a transformer neutral and ground have been recorded. Currents were found to increase at a time of magnetic disturbance. Enhanced currents are referred to as solar-induced-currents (SICs) in electrical engineering⁶ and were found to be as large as 100 A, during severe magnetic storms.

Fig. 1 A frequency-time spectrogram of chorus emission and power line harmonics (a), along with induction magnetograms of the magnetic horizontal component recorded at Riverton, Star Lake and Thompson (b). The ELF-VLF signals (magnetic component) were received on a loop antenna whose plane lay in that of the magnetic meridian. The power harmonics are seen as horizontal lines in the low frequency band below 1 kHz. Their enhancements start coincident with the initiation of the rapid negative deflection of the magnetic horizontal component.

The non-linearity in magnetisation of the transformer core materials is bound to give rise to higher harmonics in power line currents. It has been shown that the third harmonic is dominant among the higher harmonics⁷. According to our analysis, only odd harmonics are excited if the hysteresis loop of the transformer core materials has a point of symmetry, whereas both odd and even harmonics are excited in the absence of point-symmetry. In the absence of d.c. bias, the hysteresis loop of a ferromagnetic material has a point of symmetry; however, the symmetry is generally lost if a d.c. bias is applied. This readily explains why odd harmonics only (3rd and 9th) existed before the ssc whereas both odd and even harmonics (6th, 12th and 18th) were generated corresponding to the rapid magnetic fluctuations of the ssc.

The foregoing cause of SIC-induced harmonics suggests that the 10–20-s delay of the enhancements of the harmonics after the beginnings of the magnetic fluctuations on the horizontal component at Riverton may be attributed to the hysteresis of the transformer core, as the induced current must be reversed between one harmonics enhancement and the next. Possible phase differences between magnetic fluctuations and telluric currents may also be responsible for the delay.

It is appropriate to check whether the ssc-induced telluric current can be strong enough to bring the transformer cores to near saturation. If we assume that the power line is straight and l km in length, flow-pattern of the telluric currents is likely to be affected in an area of order of l^2 km². Considering a square whose side length is l km, the total current flowing across the square's side perpendicular to the power line can be estimated as follows. An abrupt magnetic field change of 1 nT is estimated to give rise to telluric currents with depth-integrated strength of ~ 1 A km⁻¹. The size of the ssc under consideration is estimated to be ~ 50 nT. Consequently, the strength of the telluric current is ~ 50 A km⁻¹. Assuming that l is 300 km, the total current flowing across the perpendicular side is $\sim 15,000$ A. A very small portion of this current, if shunted by the power line, can affect transformer cores considerably.

The observation–interpretation of the ssc-enhanced power harmonics leads to two points of interest: one scientific and one industrial. The scientific point concerns VLF chorus emissions. Chorus emissions are known to increase during magnetic substorms. This is generally understood in terms of the increased population of suprathermal electrons in the magnetosphere⁸. However, our investigation indicates that the enhancement of power harmonics during a magnetic storm may, itself, have an important role in giving rise to enhanced stimulation of emissions in the magnetosphere. The seeding of the harmonic waves is known to increase the emission activity^{9–12}, and our observation shows that the seeding process itself is enhanced during magnetic disturbances. Note that enhanced seeding of power harmonic waves means not only the increase in wave amplitude but also enrichment in spectral content, extension to higher frequencies and occurrence of even harmonics. The industrial point is that suitably distributed VLF receivers and induction magnetometers are expected to be useful for monitoring SICs in power systems. Observation of power harmonic waves by VLF receiver is expected to yield quantitative information on strength of SICs. SICs are likely to be caused by various types of magnetic variations: ssc, magnetic pulsations, polar substorm and magnetic storms. Identification of the particular type can be made through observation by induction magnetometers. Understanding the nature of SICs is expected to help find ways of minimising their undesirable effects on power generation, transmission and distribution.

Thermoluminescence and terrestrial age of the Estacado meteorite

THE terrestrial age of a meteorite is the number of years which has elapsed since the meteorite fell to Earth. The terrestrial ages of most meteorites are not known directly, as most are 'finds' rather than observed 'falls'. Here we discuss the various methods which have been suggested to determine the terrestrial age of the 'finds', and these may be conveniently divided into two categories: (1) those which use the decay of spallation-produced radioactive isotopes^{1–4}; (2) those which use the thermal drainage of thermoluminescence (TL) from the material^{5,6}.

Boeckl¹ has calculated the terrestrial ages of 19 stony meteorites from a derivation of their radiocarbon content. Among the meteorites studied was Estacado (H-group chondrite) for which Boeckl calculated a terrestrial age of $6,800 \pm 3,000$ yr. Recently, McKeever and Durrani⁷ have carried out some TL studies of Estacado, the results of which are not consistent with such a large terrestrial age. After a meteorite falls, it is shielded from cosmic rays by the Earth's atmosphere. The TL induced in the meteorite by cosmic-ray bombardment in space will thus slowly drain from the meteorite as it rests on the Earth's surface, the high-temperature ($\approx 400^\circ\text{C}$) region of the TL glow decaying much more slowly than the low-temperature ($\approx 200^\circ\text{C}$) region. The high-temperature region of Estacado's TL glow seems to be far too high to be consistent with a terrestrial age of 6,800 yr.

Figure 1 shows the high-temperature (HT) TL of 14 meteorites of known terrestrial age (that is, 'falls') and the high-temperature TL of five 'finds'. The TL is plotted either against known terrestrial age, or against deduced age from ¹⁴C

Fig. 1 The decay of the intensity of the high-temperature TL region from 14 'falls' (○) and five 'finds' (□). The ^{14}C age for Potter is from Suess and Wänke⁴. The uncertainty in the TL is estimated from the standard deviation of the high-temperature TL within a sample, based on 75 measurements of the natural TL in Estacado. The dotted curve is an estimation of the decay curve. Ba, Barwell; Br, Bruderheim; Kh, Khanpur; SB, Soko Banja; Bu, Butsura; Ol, Olivenza; Cr, Crumlin; Dh, Dhurmasa; Es, Estacado; Te, Tennesilim; Li, Limerick; Al, Aldsworth; Sa, Saratov; Je, Jelica; Ga, Gambat; Pi, Plainview; Bl, Bluff; Di, Dimmit; Po, Potter.

measurements^{1,4}. Clearly, Estacado is 'anomalous' in that the intensity of the high temperature TL is not consistent with a ^{14}C age of 6,800 yr. Indeed, the TL data suggest a true terrestrial age of 100 yr.

Further evidence is available to support a terrestrial age ≈ 100 yr for Estacado. First, its appearance is one of a reasonably 'fresh' fall. Besides rusting on the surface, the interior of the meteorite was very fresh looking (a pale grey) which, when the meteorite is compared with meteorites such as Dimmit or Potter, implies that it has a much lower terrestrial age than 6,800 yr.

Second, there is some strong circumstantial evidence to indicate that Estacado fell in 1882. Howard and Davison⁶ have given a detailed account of the find of Estacado. In 1882, a bright fireball was seen by the residents of the colony of Estacado, Hale County, Texas. The meteor was seen to fall north-west of them. In 1883 several cowboys came across the meteorite in the vicinity of the conjectured fall of the meteor. As this is a stoneless region, the inhabitants considered the meteorite to have been the cause of the fireball seen in 1882.

Viewed in the light of the account reproduced by Howard and Davison, the TL data clearly support the view that Estacado's terrestrial age is only ≈ 100 yr and not several thousands of years as deduced by Boeckl.

This discussion of Estacado's terrestrial age suggests that a useful check of a deduced ^{14}C age would be to carry out some TL measurements in order to check the consistency of the ^{14}C age with the TL properties. Similar inconsistencies have been highlighted in earlier work⁵.

An explosive volcanic eruption in the Southern Hemisphere in 1928

SEVERAL climatologists^{1–3} have compiled lists of volcanic eruptions which are thought to be of meteorological and climatological importance. Although these lists have been criticised for being incomplete⁴, subsequent authors^{5,6} have used them in studies designed to reproduce and explain the climatic history of the Northern Hemisphere. I report here additional information on two volcanic eruptions which may be climatologically significant but have generally not been considered in climate studies. By clarifying the volcanic chronology, a better test of the hypothesis that volcanoes cause part of the observed climate change can be made.

From measurements of solar radiation by the Smithsonian Astrophysical Observatory made at Mt Montezuma, Chile, Mt Brukkaros, South-west Africa, and Table Mountain, California, there is evidence for an increase in atmospheric turbidity in 1928 which can be best attributed to a volcanic eruption which ejected aerosols into the stratosphere. Paluweh (8° 19'S, 121° 42'E) in the East Indies, which caused tidal waves with its eruption in 1928, is the major cause of the decrease in atmospheric transmission at this time, although Reventador (0° 05'S, 77° 40' W) in Ecuador which also erupted in 1929 may have contributed to this decrease. Radiation records at Washington, D.C., Madison, Wisconsin, Lincoln, Nebraska, and Blue Hill, Massachusetts also show decreases in atmospheric transmission⁷. Modern climatologists have generally overlooked the volcanic eruption of Paluweh in 1928, although this was probably one of the largest eruptions between that of Katmai in 1912 and Agung in 1963.

The Astrophysical Observatory of the Smithsonian Institution made pyrheliometric observations of the normal incidence irradiance of the Sun at Mt Montezuma, Chile (22° 40' S, 68° 56' W) from 1920 to 1955. These measurements were made with silver disk pyrheliometers and Angstrom pyrheliometers at selected air mass values. Many measurements were made at sea level air mass values of 2.0 and 2.5 and are tabulated by Abbot and Aldrich⁸ and Aldrich and Hoover⁹. The true air mass values are 1.44 and 1.80 for the mean station surface pressure.

The ratio of the pyrheliometric measurements at air mass 2.5 to that at 2.0 provides a relative measure of atmospheric transmission¹⁰ which is independent of the pyrheliometer calibration. Ratios are calculated on each day for which the pair of observations are available. Monthly means are calculated from the daily values. For those months with no data, the average value of all the months with the same name is used. The resulting time series is then smoothed by using a 13-month running mean average to remove seasonal variations. The resulting transmission curve is shown in Fig. 1.

Most of the features of this curve can be explained by known causes. The low transmission values before 1926 are caused by the volcanic eruption of Puyehue, Chile (40° 35' S, 72° 08' W) in December 1921 (refs 11, 12). The decrease in atmospheric transmission in 1932 was caused by the eruption of the Quizapu crater of Cerro Azul (35° 39' S, 70° 46' W) in Argentina in April 1932. A volcanic cloud 15 km in height was observed¹². This stratospheric event was observed throughout the Southern Hemisphere¹³ and ash fell over much of South America¹⁴. From Fig. 1 it can be seen that it took 2–4 yr for the atmosphere to return to normal transmission. This behaviour is characteristic of a violent volcanic eruption in which aerosols are injected into the stratosphere. After 1950 the atmospheric transmission decreases because of local contamination by a copper smelter at the Chuquicamata mine located north of the station. This local

Fig. 1 The 13-month running mean values of the ratios of the pyrhelimeter measurements at air mass 2.5 to that at air mass 2.0 at Mt Montezuma, Chile. It is a measure of the relative atmospheric transmission. The increase in optical depth for air mass 1 after the eruption of Paluweh in 1928 averaged about 0.02 for 6 months after the eruption at Mt Montezuma. The times of the eruptions of Paluweh (1928) and Quizapu (1932) are indicated by arrows. Because running means are used, the apparent atmospheric transmissions seem to start decreasing about 7 months before the date of the eruption.

contamination becomes particularly evident in late 1952 with the opening of a major smelter.

Another decrease in atmospheric transmission is observed starting in 1928. The decrease and subsequent slow rise in atmospheric transmission is very similar to the event of 1932. It seems to be a stratospheric volcanic event in July or August 1928, but it is not mentioned in the usual lists of explosive volcanoes¹⁻³. The Smithsonian observations of the aureole showed an increase in brightness, and the pyrhelimetric measurements a decrease in intensity at this time in a manner similar to that in the period after the Quizapu eruption. There was no appreciable change in total precipitable water. The measured solar constants of the Smithsonian Astrophysical Observatory at Mt Montezuma, Table Mountain and Mt Brukaros also decreased at this time which is an indication of increased atmospheric turbidity because of errors in their reduction scheme¹⁵. Clearly, the decrease in atmospheric transmission in 1928 was caused by an increase in the stratospheric dust loading both because of the long period of decreased atmospheric transmission and because it was observed worldwide. Indeed, Störmer¹⁶ photographed stratospheric dust clouds in Europe in January 1929 which may have originated from the 1928 volcanic eruption.

Although several volcanoes erupted in the period 1927-29, the eruption of Paluweh in the Isle Flores or the East Indies was the primary cause of the increase in turbidity observed at Mt Montezuma. Paluweh was active from 4 August to 25 September 1928 (ref. 17) and was the only violent volcanic eruption at this time. The eruption was accompanied by a tidal wave and the creation of three craters with diameters 80-600 m wide. The decrease in atmospheric transmission at Mt Montezuma was observed immediately after this eruption and continued for about 2 yr.

Reventador (0°05' S, 77°40' W) in Ecuador erupted in 1929 with ash rains evident in the Andes¹⁸. This eruption may have prolonged the decreased atmospheric transmission and may account for the double-bottomed depression in Fig. 1. Other minor eruptions in 1928 were Slamet (7°14' S, 109°12' E) in Java, Bromo (7°56' S, 112°57' E) in Java, Raung (8°07' S, 114°02' E) in Java, Ili Werung (8°32' S, 123°35' E) in the Lesser Sunda Islands, and Batuk Petarangan (7°10' S, 109°49' E) in Java. Active volcanoes in 1929 include Quizapu, Mt Pelee on Martinique, and Asama in Japan.

Hand⁷ independently confirms that Paluweh was the major contributor to increased turbidity in 1928 and 1929 using the Weather Bureau pyrhelimeter data. His brief mention of an eruption in the Isle Flores, Dutch East Indies, seems to be the only previous comment on a volcanic eruption at this time in the meteorological literature. At Washington, D.C., Madison, Wisconsin, Lincoln, Nebraska, and Blue Hill, Massachusetts, the atmospheric transmission decreased beginning in April of 1929. The Southern Hemisphere autumn is the most favourable time for the transport of stratospheric aerosols across the Equator^{2,19}, hence the delay of 6-8 months of the effect of the eruption of Paluweh on the radiation records in the US. Meinel and Meinel²⁰ found a comparable delay before volcanic dust from the Agung eruption became evident over the US; Paluweh and Agung are located close to each other. From the Smithsonian records, the Lamb dust veil index for this volcano seems to be about 100, thus making it the most important eruption between Katmai in 1912 and Agung in 1963. The decrease in atmospheric transmission in the US after the Paluweh eruption was about 30-40% of that observed after the Agung eruption.

The eruptions of Paluweh in 1928 and Quizapu in 1932 may have had a worldwide effect on the mean surface temperature, as indicated by Fig. 2 taken from Oliver⁵. One year after both eruptions there was a decrease in the mean surface temperature of the Northern Hemisphere of the order of 0.3 °C. Miles and Gildersleeves²¹, have shown that 1 yr after a major volcanic eruption there is on the average a decrease in the mean surface temperature of 0.29 °C and that there is only 'a small probability of the result being due to chance.' Mass and Schneider⁶ find that the depression in surface temperatures 1 yr after a volcanic eruption is significant at better than the 99% confidence level. Humphreys²², Mitchell²³, Yamamoto *et al.*²⁴, and others reach similar conclusions based on experimental data, and Hansen *et al.*²⁵, Baldwin *et al.*²⁶, and others support these observations by theory. Thus, there is reason to believe that the depressed surface temperatures in 1929 and 1933 may have a cause and effect relationship with the volcanic eruptions occurring 1 yr earlier. These drops in temperature may occur by chance but the probability of this happening is low, probably less than 1%. From Budyko²⁷, the year-to-year variation in the Northern Hemisphere annual mean surface temperature is 0.12 ± 0.097 °C for the period 1923-54. Therefore, the probability of a 0.3 °C temperature change being caused by chance alone is about 1% or less using three standard deviations as a guide. Furthermore, the probability of successfully identifying the years when the temperature decreases will occur only from a knowledge of the dates of the major volcanic eruptions is even less. In short, there is a strong suggestion that the volcanic eruptions affect climate 1 yr afterwards but not longer. Further studies of these eruptions and their effect on atmospheric transmission and climate will be needed to confirm these conclusions.

Fig. 2 The Northern Hemisphere temperature anomaly ($^{\circ}\text{C}$) as given by Oliver⁵. Major volcanic eruptions are indicated below. Events 1 and 2 correspond to the volcanic eruption of Paluweh in 1928 and to the Quizapu eruption in 1932. These Southern Hemisphere volcanic events may have affected the Northern Hemisphere temperatures, as can be seen by the decrease in temperatures about 1 yr after the two events. (The arrows for Paluweh and Quizapu are primarily used to indicate the times of their eruptions, not their strength.)

Most climatologists¹⁻³ have failed to include these eruptions in their lists and have included other volcanic eruptions which do not show up in the radiation records. For example, Oliver⁵ omits these eruptions in his analysis of the Northern Hemisphere surface temperatures, but it seems that volcanic dust originating in the Southern Hemisphere can cross the Equator and significantly affect the climate in the Northern Hemisphere. However, we emphasise that not all features of the climatic record can be explained by volcanic eruptions, although certain fluctuations in climate do seem to be caused by this mechanism. The climatology of the Southern Hemisphere is not yet well enough established in the 1920s to determine the effect of the eruption of Paluweh on the climate of the Southern Hemisphere.

Stimulated resonance between electrical and shear fields by a colloid system

CERTAIN polymer solutions have been shown using a Couette shear dielectric cell¹ to exhibit changes in dielectric properties when subjected to a shear field^{2,3}. For polar polymers which lack flexibility, the action of a rotational shear field alters the time-dependent distribution of dipole orientation which results in changes of permittivity, loss magnitude and relaxation frequency². In quantitative terms these changes seem to correspond well with the theoretical treatment due to Barisac⁴. A distinct difference in the situation occurs when flexible polymers such as poly(styrenes) or poly(*p*-ethoxystyrenes) are subjected to such shear fields. The changes are inconsistent with the magnitude of the polymer dipole and solvent relative permittivity takes on a rather dominant role⁵. To test the importance of variation of the internal field term on shape changes due to polymer coil distortions, we have studied an organic colloid system: cross-linked poly(ethylacrylate) dispersed in heptane and stabilised with a 'comb' graft copolymer [poly-(12-hydroxy stearic acid) terminated with glycidyl methacrylate and then copolymerised (1:1) with methyl methacrylate]⁶.

This latex system consists of rubbery particles of 0.4 μm average diameter which can presumably shear distort. We observed a resonance (Fig. 1) between the shear field (shear rate G (s^{-1})) and electric field f (Hz). We know of no previous observation of such a phenomenon.

Certain preliminary observations suggest a mechanism for the effect. A study of the frequency dependence of relative permittivity (ϵ') and loss (ϵ'') in the absence of a shear field indicates, as shown in Fig. 2, that the heptane dispersed colloid has a high relative permittivity at low frequency and that at least two loss

processes are present. One occurs with a maximum at such a low frequency ($<10^2$ Hz) that its resolution is not possible with our audio frequency bridge equipment; the other apparently occurs at a frequency $\sim 10^3$ Hz as indicated by spot coaxial line and wave guide measurements. Even attempts to shift the low frequency process completely into the range of measurements ($>10^2$ Hz) by increasing the temperature to 60°C failed, though a partial shift did take place. A further temperature increase was not practicable due to solvent volatility. The large value of the relative permittivity at 10^2 Hz of a 40% dispersion above that of pure heptane (Fig. 2) together with the presence of two loss

Fig. 1 Resonances in relative permittivity (ϵ') (a) and dielectric loss (ϵ'') (b) for the organic colloid in shear (rate G (s^{-1})). Numbers give polarisation frequency f (Hz).

processes at vastly different frequencies suggest that dissimilar mechanisms are responsible. The high frequency process is probably dipolar whereas that at low frequency is in our view interfacial (Maxwell-Wagner), although a dipolar origin in the poly(ethylacrylate) cross-linked phase cannot be ruled out. We favour an ionic-conductance process due to trace impurity ions, through or over the surface of the particles, promoting interfacial polarisation rather than orientation polarisation because of its low frequency, large magnitude and its agreement with a mechanism described below. Also, at the frequency of this process a bulk conductivity term is present shown by values of ϵ'' exceeding the incremental relative permittivity ($\Delta\epsilon'$).

On the basis of an interfacial polarisation the resonances shown in Fig. 1 originate in a coupling between electric field-induced charge displacement and forced rotation of the particles by the shear field. Indeed, the condition for the position on the shear-rate axis for such maxima (G_{max}) can be predicted to occur when the angular frequencies of polarisation and rotation match. The condition that $2\pi f = G_{\text{max}}/2$ follows if the particles are spherical and rotational diffusion has no influence⁶. Angular fluctuations due to brownian motion for such large particles will be small and even if significant, are not likely to alter the position of the maximum. The neglect of diffusion is therefore justified. It follows that f should be proportional to G_{max} and this is shown in

Fig. 2 The increment in relative permittivity ($\Delta\epsilon' = \epsilon'_{\text{solution}} - \epsilon'_{\text{solvent}}$) (a) and dielectric loss (ϵ'') (b) of the organic colloid in heptane. $\bullet$, 30° ; $\circ$, 60° . Dashed line is interpolation based on limited data.

Fig. 3. Also shown in Fig. 3 is the theoretical line of slope $(4\pi)^{-1}$. The slight discrepancies we attribute to inaccuracies in gap measurement. An error of $1.3 \mu\text{m}$ in the gap measurement of $23 \mu\text{m}$ would account for the divergent slopes: this is within the limits of the capacitance based measurement¹.

Work is proceeding on this resonance phenomenon and its application to aqueous media. This important class of polymer systems, which includes biopolymers in their natural environment, presents considerable problems in dielectric studies in the kHz-MHz frequency range because of the screening effect of bulk conductance. We have experimentally established with dioxan-water mixtures that bulk conductance in isolation does not give rise to a shear-induced resonance in permittivity. Thus, this resonance phenomenon may possibly be used to decouple

Fig. 3 The dependence of shear rate at maximum resonance (G_{max}) on f . The theoretical dependence of slope $(4\pi)^{-1}$ is shown as a dashed line.

dielectric relaxations, particularly interfacial ones, from the screening effect of bulk conductivity.

We thank ICI Paints Division for the supply of the organic colloid and for helpful discussions, also the SRC for an equipment grant and for a postgraduate studentship to E.M.G.

Epitaxial synthesis of diamond by carbon-ion deposition at low energy

THIN epitaxial layers have been grown in vacuum by the controlled deposition of low-energy carbon ions on to heated single crystal diamond substrates by a process described here. Reproducible crystalline growth, up to 10 μm in thickness and up to several mm^2 in area, has been observed on both natural stones and polished diamond plaques¹. Three competing forms of ion-deposited carbon have also been characterised.

Various methods of diamond synthesis have been reported; the most successful involve growth at elevated temperature under very high pressure. Limited success has also been achieved in the metastable region by vapour-phase epitaxy at low pressure², but such procedures are constrained by the spontaneous graphitisation of diamond at high temperatures. At the lower temperatures which have been used, the scale and the quality of crystalline growth are severely limited by the competing formation of other modifications of carbon.

In 1971, Aisenberg and Chabot³ described the production of 'diamond-like' films by the deposition of low-energy carbon ions on a variety of surfaces. The depositions were carried out at room temperature and the substrates did not include diamond. The further characterisation of such films by ellipsometry and X-ray and electron diffraction has been reported by Spencer *et al.*⁴. Although the properties of the deposits were variable, there was evidence of polycrystallinity with definite, but usually very weak, X-ray lines assignable to diamond.

In 1967 J.H.F. described the adaptation of a heavy-ion accelerator for a variety of ion-bombardment studies on semiconductor substrates⁵. These included the study of epitaxial growth through the deposition of low-energy silicon ions on heated wafers of single crystal silicon. Such epitaxy is to be expected and it simply reflects the thermodynamic stability and the established vapour-phase growth behaviour of crystalline silicon. It has been subsequently confirmed in more detailed studies⁶ using low-energy silicon and germanium ions. The situation with respect to carbon is quite different; not only is diamond metastable in such deposition conditions, but it has also been observed that the radiation damage due to ion bombardment can result in irreversible graphitisation⁷.

Nevertheless, some encouraging indications of diamond synthesis were obtained in an initial feasibility study carried out in 1972. Carbon ions with an energy < 100 eV were deposited on to a small area of a heated diamond plaque. The resulting brown layer, ~3,000 Å in thickness, resisted simple abrasion

Fig. 1 Interferometric micrograph of an epitaxial deposit on a polished diamond plaque. Note the carbonaceous inclusions in the deposited layer.

tests and showed evidence of crystallinity when studied by proton channelling. It thus seemed that the very localised dissipation of energy as the ions were stopped on, or very close to, the surface may have assisted epitaxial growth by inducing mobility at an acceptable substrate temperature.

A wide range of experiments was carried out subsequently on a much improved ion-deceleration apparatus⁸ installed on a Harwell/Lintott type of heavy-ion accelerator. These demonstrated that the deposition process is complex and that at least three other forms of carbon can compete with the epitaxial synthesis. It was also found that, at low ion energies, even slight surface contamination affects the reproducibility of deposition. The most consistent results and the best quality of growth were obtained using carbon ions at an energy of around 900 eV on carefully cleaned diamond plaques, heated to about 700 °C. The layers, which were deposited to a thickness of several micrometres at a rate of a few thousand Ångströms per hour, regularly contained a low density of carbonaceous inclusions but otherwise apparently represented continuous epitaxial growth on the crystalline substrate.

An interferometric micrograph of an epitaxial deposit containing inclusions on a polished diamond plaque is shown in Fig. 1. Evidence of crystallinity in such a layer can be seen in the reflection high-energy electron diffraction pattern (RHEED) in Fig. 2. Various other techniques were also used to characterise the ion deposited layers. Finally, on the basis of the accumulated experience with a large number of samples, it was concluded that non-epitaxial carbon could be confidently distinguished and removed by extended polishing with alumina powder followed by controlled air oxidation for periods up to two weeks. The epitaxial growth was totally resistant to such treatment.

It was found that the density of the carbonaceous inclusions could be substantially reduced by rigorous precleaning of the substrate but they were never completely eliminated. They seem to be a lower density form of carbon than diamond and they consequently grow steadily in size as the deposition proceeds. It was thus found that they provide an ultimate limit to the

Fig. 2 Reflection high-energy electron diffraction (RHEED) pattern of an ion-deposited epitaxial layer.

thickness of crystalline growth which can be achieved in a single stage.

In some experiments a continuous smooth deposit with a lower reflectivity and density than diamond was observed in place of the epitaxial growth. The nature of these carbonaceous layers which may have been associated with the use of a conventional oil-pumped vacuum system, varied markedly from sample to sample. Additionally, a matt black form of carbon was sometimes observed at the edge of deposits when masks were used to define the boundary of growth. A fuller account of this work will be published elsewhere.

We thank D. Chivers, M. Warman and D. Beanland for help with the experiments and R. S. Nelson, J. A. Cairns, J. C. Riviere and their colleagues who assisted with the characterisation of the deposits. Financial support by the NRDC is gratefully acknowledged.

The role of hydrogen sulphide in environmental transport of mercury

HYDROGEN SULPHIDE may be evolved in anoxic sulphur-containing river or lake sediments¹. The effect of the presence of sulphide on the availability of inorganic mercury for biological methylation has been considered previously. Essentially mercury in the form of Hg(0) or Hg(II) may be converted into mercuric sulphide in anoxic sediments². It might seem that this very insoluble material would not, in practice, be available for methylation and that sulphide formation would act as a method of removing mercury from availability to the general environment (that is, it would act as a mercury sink). However in a complex natural system (aquarium sediment) it has been shown that HgS may, in fact, be methylated in the sediments although to produce quantities of methyl mercury substantially less than those produced using a more soluble mercury substrate². Therefore, although H₂S in a sediment would be expected to reduce the rate of mercury methylation considerably by the formation of HgS, it would not be expected to prevent formation of methyl mercury entirely. The effect of H₂S on methyl mercury itself has also been investigated using a purely inorganic model³. An aqueous solution of methyl mercuric chloride (1 mg dm⁻³) loses methyl mercury steadily over 3 days after initial exposure to H₂S. A volatile product was evolved into the space above the solution. This product was trapped in a sodium carbonate-disodium phosphate solution, extracted with toluene and shown to co-migrate with methyl mercury on thin layer plates of silica gel. It was concluded that the evolved product of the reaction system was a volatile organo-sulphur derivative of mercury that reverted to methyl mercury on extraction. These observations suggest that reaction between methyl mercury and H₂S generated in sediments reduces the amount of methyl mercury available for accumulation by fish and shellfish and represents a

powerful mechanism adding to the general mobility of mercury compounds in the environment. It is therefore important to identify the unknown mercury compound evolved from the system described above. We have now investigated the interaction of H₂S with River Mersey (England) inter-tidal estuary sediment samples in order to determine its effect on methyl mercury levels in real systems. We have also investigated similar reactions in a model system, leading to the identification of the previously unknown volatile mercury species responsible for the transport of mercury in the work of Rowland *et al.*³

Our experiments with the model system were similar to those described previously³, but we used a gas chromatographic technique rather than radiochemical labelling to estimate methyl mercury losses. Aqueous solutions of CH₃HgCl (concentration about 1 mg dm⁻³) were placed in screw top bottles fitted with silicone rubber septa. H₂S or N₂ (for control samples) was passed through the solutions for 2 min. At intervals solution samples were extracted by syringe from each bottle and analysed for methyl mercury as follows.

Fig. 1 Volatilisation of CH₃HgCl from aqueous solution by H₂S. Initial concentration of solutions was 1 mg dm⁻³. There was an immediate rapid decline to 0.85 mg dm⁻³ for both solutions owing to adsorption on vessel surfaces. This initial decline over the first few minutes of the experiment has not been included in the graph. Temperature, 18 °C.

An aliquot of 0.1 cm³ of each solution was placed in a tube and N₂ gas passed over the solution for 30 s to remove excess H₂S. (CH₃HgCl is not affected by this procedure.) The sample solution was then shaken with 1 cm³ benzene (GLC grade) and 0.1 cm³ CuSO₄ solution (10%) for 2 min. The benzene layer was removed and the methyl mercury content determined by electron-capture gas chromatography as described previously⁴. We found that methyl mercury was steadily lost from the original solution and a typical example from an experiment of this kind is shown in Fig. 1. These results are not incompatible with those of Rowland *et al.*³ although our experiments were conducted over a rather longer period.

As the gas chromatographic technique used was probably specific for monomethyl mercury, an attempt was made to identify any other species in the solution using ¹H NMR spectroscopy. The NMR spectrometer used (Jeol C60-HL) could detect methyl mercury in concentrations of >0.5%. Because of solubility difficulties with the chloride we carried out NMR experiments using methyl mercuric acetate at a concentration of

Fig. 2 Two chamber vacuum vessel. Apparatus designed for connection to mass spectrometer vacuum line. (Taps used: glass/PTFE—J. Young, London.)

1% in D_2O . NMR spectra of $CH_3HgOCOCH_3$ in D_2O show three principal peaks for methyl mercury, acetate-methyl and residual water at 9.0, 8.0 and 4.3 τ values respectively. For the H_2S experiment, 0.25 cm³ of 2% $CH_3HgOCOCH_3$ solution in D_2O was mixed with 0.25 cm³ of saturated H_2S solution in D_2O in an NMR tube (a white precipitate formed immediately). The tube was then sealed and a spectrum recorded. The NMR spectrum showed peaks only for acetate-methyl and H_2O . The H_2S peak did not appear owing to proton exchange with D_2O . The absence of the methyl mercury peak shows that the formation of the white precipitate has reduced the methyl mercury concentration in the solution to below that detectable by the NMR technique.

The control (no H_2S) and the experimental sealed NMR tubes were re-examined several times over a 14-day period. No changes in the spectra were seen over this period. The white precipitate, however, did change colour slowly from white to black.

The initial white compound was prepared, separately, from H_2S solution and $CH_3HgOCOCH_3$. After recrystallisation from ethanol, the melting point was found to be 142 °C at which temperature the compound decomposed to a black solid. A mass spectrum was run of the white compound whose highest m/e values and characteristic mercury isotope pattern (see for example ref. 5) and distribution demonstrated it to be $(CH_3Hg)_2S$. The melting point is consistent with the literature melting point (143 °C) for $(CH_3Hg)_2S$ (ref. 6).

It seems then that loss of methyl mercury from aqueous solution on exposure to H_2S is caused initially by formation of $(CH_3Hg)_2S$. The solutions used by Rowland *et al.* and in our GLC experiments were much more dilute than the solutions used for NMR, and this might account for a slower appearance of $(CH_3Hg)_2S$ in our GLC work. The subsequent change of

white $(CH_3Hg)_2S$ to a black material represents a further reaction that may account for the actual volatilisation and loss of mercury from the system.

An experiment was devised to try to identify the volatile product(s) by mass spectrometry. A two-chamber vessel (Fig. 2) was constructed such that the aqueous phase reaction between CH_3HgCl and H_2S could be carried out with subsequent separation of any volatile products. Twenty-five cm³ of aqueous CH_3HgCl (1 g dm⁻³) were placed in the lower section and N_2 (control experiment) or H_2S was passed through the solution for 2 min. With H_2S a white precipitate formed immediately. After 3 days in the closed system the upper chamber was evacuated and any volatiles present in the lower chamber were allowed to pass into this upper section. The apparatus was connected to a vacuum line system attached to a mass spectrometer (V.G. Micromass 16B). The contents of the upper vessel were trapped out using liquid nitrogen in a section of the vacuum system. After initial warming excess H_2S was pumped away and the trap contents were allowed to enter the mass spectrometer. The characteristic mass spectrum of dimethyl mercury was observed. The compound was identified by the characteristic isotope pattern observed for mercury⁵ surrounding m/e 232, 217 and

Fig. 3 Analysis of sediment samples (Hale Point, Mersey Estuary) for methyl mercury. Samples stored at room temperature (18 °C). ●, Untreated; ○, H_2S treated samples.

202 corresponding to $(CH_3)_2Hg^+$, CH_3Hg^+ and Hg^+ . The control sample did not evolve observable amounts of CH_3HgCl into the vapour phase and hence we conclude that our observed CH_3Hg^+ and Hg^+ peaks were caused by breakdown of $(CH_3)_2Hg$ not evolution of CH_3HgCl . In any case we observe no peaks corresponding to m/e 254 and 252 for CH_3HgCl , nor any $HgCl^+$ species at 239 and 237. This evidence suggested that only $(CH_3)_2Hg$ had been evolved. We could find no evidence for CH_4 or any mercury sulphur species. Comparison with standard mass spectra of known samples of $(CH_3)_2Hg$ and CH_3HgCl reinforced these conclusions. We could find no evidence for the presence of suitable mass ratio peaks for compounds such as CH_3HgSCH_3 and CH_3HgSH . The H_2S experiment was repeated using a 1 mg dm⁻³ solution of CH_3HgCl but this was too low a concentration for detection in our apparatus.

The results of this series of experiments suggest that Rowland *et al.*³ observed the evolution of volatile $(CH_3)_2Hg$ from the reaction between H_2S and CH_3HgCl . $(CH_3Hg)_2S$ was apparently formed as an intermediate in the reaction. This compound gradually decomposes to black β - HgS and $(CH_3)_2Hg$. This is in accord with the known chemistry of this species^{7,8}.

Our results for CH_3HgCl levels in solution differ in small detail from those of Rowland *et al.* who measured total CH_3Hg species remaining in solution, whereas our technique measures water soluble CH_3Hg species remaining in solution. This would include CH_3HgCl and possibly, to a small extent, $(\text{CH}_3\text{Hg})_2\text{S}$. In our experiments a precipitate of $(\text{CH}_3\text{Hg})_2\text{S}$ was observed. Rowland *et al.* do not mention this and it is likely that at the higher temperatures they used (37°C) a precipitate was either not present or present only to a very small extent. Our experiments were carried out at 18°C .

The rapid early loss of methyl mercury found in our experiments is probably due to initial rapid formation of some $(\text{CH}_3\text{Hg})_2\text{S}$ to an equilibrium level, followed by a slower decay of the sulphide to dimethyl mercury which is lost from solution.

The question arises as to how much significance these reactions have for environmental situations. In our experiments on the analysis of estuarine sediments for methyl mercury we have observed changes in methyl mercury levels over a number of days following sampling⁴. Changes in the redox conditions of the sediment following sampling were suspected as a possible cause of this effect. In a series of such experiments we passed H_2S through a container of freshly-sampled sediment; the sediment was later sub-divided into a series of bottles. Single bottles were analysed for methyl mercury over 28 days and compared with a control set which was not exposed to H_2S .

These experiments have demonstrated that diffusion of H_2S in a sediment significantly reduces the level of methyl mercury in that sample relative to a control (Fig. 3.). We have also been able to show that dimethyl mercury is evolved into the gaseous phase from a mercury-containing sediment which has been treated with H_2S . A control sediment not exposed to H_2S did not evolve $(\text{CH}_3)_2\text{Hg}$ in detectable quantities. For this latter experiment we were forced to raise the concentration of methyl mercury to $100\text{ }\mu\text{g g}^{-1}$ by 'spiking' with CH_3HgCl . At natural concentrations of methyl mercury, of the order of 15 ng g^{-1} , we could not detect $(\text{CH}_3)_2\text{Hg}$ in control or H_2S exposed samples.

Our results suggest that monomethyl mercury species in sediments may be mobilised into the atmosphere as $(\text{CH}_3)_2\text{Hg}$ if H_2S is generated in the sediments. This points to a natural mechanism for the removal of mono-methyl mercury from situations where it may be incorporated into fish. In positively identifying $(\text{CH}_3)_2\text{Hg}$ as the volatile species another route in the general mercury cycle has been demonstrated. In view of the potential generation of further monomethyl mercury species from the large 'reservoir' of inorganic mercury that accompanies monomethyl mercury in sediments⁹, there is the possibility of volatilisation of larger amounts of mercury than the equilibrium amounts of methyl mercury present.

We thank the SRC for support for purchase of GLC equipment and Leicestershire County Council for a research assistantship for PDB. We also thank Mrs D. Sutherland, Mr M. I. Needham and Dr A. Temple for assistance and useful discussions.

Reevaluation of the role of dimethyl sulphide in the sulphur budget

THE possible existence of an oceanic source of atmospheric SO_2 has recently been suggested for the following reasons. First, to account for the observed¹ SO_2 background concentration of $0.1 \times 10^{-6}\text{ g m}^{-3}$ of air, even very far from any continental source and in areas as remote as the Antarctic ocean—despite a residence time for SO_2 in the marine atmosphere of $\sim 0.7\text{ d}$ (refs 2, 3). Second, because another major source such as the ocean is necessary to complete the global atmospheric sulphur budget⁴⁻⁷. Because of the basic pH of seawater, SO_2 cannot be emanated directly from the oceans. According to Lovelock *et al.*⁸, the dimethyl sulphide (DMS) produced in the sea by many living systems, could be evolved in a first step into the atmosphere and subsequently oxidised to SO_2 . These authors observed a mean DMS concentration of the order of $12 \times 10^{-9}\text{ g l}^{-1}$ in Atlantic ocean water. We have developed an improved method for the measurement of DMS in seawater and have used this technique on several recent oceanographic research cruises. Our results suggest that the oceans could contribute over 30% of the amount of sulphur required to balance the sulphur budget.

DMS was first extracted from the seawater using carbon tetrachloride, then by 5% aqueous solution of mercuric chloride as a Hg^{2+} -DMS complex which remains stable for more than 6 months. In the laboratory, DMS was released by 6 M HCl, redissolved in propan-2-ol at -35°C and finally measured by gas chromatography with a flame photometric detector. The limit of detection is $5 \times 10^{-11}\text{ g}$ of DMS. With the usual yields, this figure corresponds to a limit of $5 \times 10^{-9}\text{ g l}^{-1}$ for a 15-l sample of seawater.

A preliminary list of DMS concentrations for the Atlantic and Indian Ocean waters is shown in Table 1. The lowest values found agree well with the results of Lovelock *et al.*⁸. The highest concentrations observed (samples 1, 4 and 12) characterise areas with presence of algae (principally of *Fucus* and *Ascosiphium* with *Polysiphonia Lanosa*). Sample 2 was taken in water highly polluted by oil, 1 week after the oil spill of the Amoco Cadiz.

We determined levels of DMS in the microlayer and the concentration distribution with depth in the Mediterranean. To the best of our knowledge, this is the first report of such measurements. Surface microlayer samples (about $400\text{ }\mu\text{m}$) were obtained by using the Garrett screen⁹. The DMS concentrations found for these samples are given in Table 2.

As a general rule, the values observed in the Mediterranean are significantly higher than in the Atlantic. The concentrations

measured in samples 13 and 14 seem to be anomalously high. Possible contamination during the sampling can be ruled out, however, because of the strict precautions taken (for instance, the water was sampled from a small dinghy 1 km forward of the ship). The microlayer is more concentrated in DMS than the subsurface water, with ratios of microlayer and subsurface

levels of between 1.2 and 5.3. Similar ratios (~ 3) have been observed for particulate organic carbon and nitrogen in the microlayer^{10–13}.

The DMS depth profiles obtained are shown in Fig. 1 together with those of temperature, salinity and density of the seawater. These profiles show the existence of high DMS concentration layers under the sea surface. The maximum DMS concentrations seem to be connected with a sharp variation in the gradient of density and therefore to a dynamically stable water layer. A similar observation is usual in the case of marine particulate matter.¹⁴

From these preliminary studies, we can draw several conclusions. First, a very large range of DMS concentrations is observed in the superficial seawater, the figures previously obtained by Lovelock⁸ appearing to be a lower limit rather than typical of the average oceanic value. Second, the DMS concentration also varies quite rapidly with depth: factors of 3 have been observed, as in Fig. 1, between the surface and the depth of the maximum concentration (10 and 30 m). These maximum DMS concentration layers seem to be able to move up, and to reach the surface, which could explain the existence of sometimes very high surface DMS concentrations. Both of these observations suggest that the mean oceanic DMS concentration should be of the order of $30 \times 10^{-9} \text{ g l}^{-1}$ instead of $12 \times 10^{-9} \text{ g l}^{-1}$ indicated by Lovelock⁸. Third, from the knowledge of the oceanic content of DMS, it should be possible to evaluate the flux of this sulphur compound to the atmosphere. Liss and Slater¹⁵ have suggested a method of calculation based on Fick's law of molecular diffusion and a Henry's law constant of 0.3:

$$F = K_1(C_{\text{air}} - C_1)$$

where F is the DMS flux ($\text{g cm}^{-2} \text{ h}^{-1}$), K_1 the exchange constant equal to 19.2 cm h^{-1} , C_{air} and C_1 respectively the DMS concentration in the air (negligible¹⁶) and in the seawater immediately under the molecular diffusion layer, that is here the microlayer concentration.

According to the present work, $C_1 > 90 \times 10^{-9} \text{ g l}^{-1}$ which is 3 times the mean subsurface concentration, since the sampling method of the microlayer partially mixes the superficial film with the subsurface water. This formula gives for the oceans a flux of at least $2.7 \times 10^{13} \text{ g yr}^{-1}$ of sulphur. Such a flux could represent more than 30% of the amount needed to balance the sulphur budget.

Fig. 1 DMS depth profile.

Derivation of K-rich ultramafic magmas from a peridotitic mantle source

THE genesis of a wide spectrum of basaltic magmas by partial melting of a peridotitic upper mantle with small amounts of H_2O as its only volatile component is well established¹⁻³, as is the role of CO_2 in magma genesis in the upper mantle^{4,5}. However, the origin of K-rich mafic to ultramafic magmas has not been satisfactorily explained by mechanisms involving partial melting of commonly accepted upper mantle sources. We report here experiments on an olivine ugandite from Bufumbira, south-west Uganda⁶, in conditions of H_2O and H_2O-CO_2 mixtures ($x_{CO_2} \sim 0.75$) up to 40 kbar, and at an $f_{O_2} \gg Ni-NiO$ buffer⁷. These are the first experiments reported on a lava of the ultramafic alkaline type with $K_2O > Na_2O$ using both H_2O and CO_2 as volatiles and showing that K-rich ultramafic magmas can be derived by partial melting of a 'normal' peridotitic mantle containing both H_2O and CO_2 . Olivine ugandite is believed to be the most primitive lava occurring in this K-rich province^{6,8-10} and may reasonably be considered as a model composition for K-rich ultramafic magmas generally.

Magmas with increasing degrees of undersaturation can be produced only by progressively decreased amounts of partial melting of a peridotitic upper mantle if H_2O is the only volatile component present³; olivine nephelinites or olivine basanites represent the most undersaturated types¹¹. Experiments up to 40 kbar on an olivine melilitite^{7,11,12} indicate that partial melting of an upper mantle source containing H_2O alone cannot produce such a magma, whereas partial melting of an upper mantle peridotite containing both H_2O and CO_2 ($x_{CO_2} \sim 0.75$) provides a satisfactory mechanism. Experiments on such magmas using both H_2O and CO_2 as volatile components have only involved compositions with $Na_2O \gg K_2O$. A high pressure study¹³ of a very K_2O -rich lava shows that such lavas cannot be produced by partial melting of a peridotitic mantle in which H_2O is the only volatile component.

Figure 1a shows the results of experiments in anhydrous, 5%, 15% and water-saturated conditions. The absence of orthopyroxene and garnet and the dominance of olivine and clinopyroxene at, or near, liquidus temperatures precludes the possibility of this magma being derived by partial melting of a peridotitic mantle source containing only H_2O . In contrast to studies of a composition richer in K_2O (ref. 13), phlogopite in the olivine ugandite does not occur in near-liquidus conditions (Fig. 1b), indicating that mechanisms of differentiation involving early fractionation of phlogopite¹³ are untenable.

Figure 1c shows phase relations with $x_{CO_2} \approx 0.75$ representing 27.5% weight CO_2 and 3.8% weight H_2O (equivalent to the 15% weight H_2O conditions of Fig. 1b). In these conditions, orthopyroxene, clinopyroxene and spinel are the near-liquidus

Fig. 1 P - T projection of olivine ugandite composition. a, Liquidus relations in anhydrous, 5% H_2O , 15% H_2O and H_2O -saturated conditions. b, Liquidus and subliquidus relations at 15% H_2O . c, Liquidus and subliquidus relations with H_2O and CO_2 at $x_{CO_2} \approx 0.75$ (mol %). O, Above liquidus; ■, olivine; x, clinopyroxene; +, orthopyroxene; ●, phlogopite; □, spinel; ◇, garnet.

phases at 20 kbar and orthopyroxene is the near-liquidus phase at 30 kbar, closely followed by garnet and clinopyroxene. Comparison of these results with those for an olivine melilitite^{7,11,12} indicates that the olivine ugandite could be produced by very small amounts of partial melting (<5%) of a peridotitic mantle source containing both H_2O and CO_2 .

Calculations using the microprobe analyses of the minerals crystallised in our experiments indicate that it is highly unlikely that mechanisms involving fractionation of garnet and/or orthopyroxene can develop a K-enrichment trend from parental magmas of olivine ugandite compositions. However, calculations using data on the minerals present in the runs done with 15% H_2O as the only volatile component (Fig. 1b) show that sequential fractionation of olivine, olivine + clinopyroxene, and olivine + clinopyroxene + phlogopite between about 20 kbar and 1,200 °C to about 10 kbar and 1,000 °C can produce successive liquids with compositions closely corresponding to the olivine ugandite-ugandite-olivine leucitite-leucitite series of the Bufumbira region⁶. Such liquids show an enrichment in K relative to Na (as $100 K/(K+Na)$) from 41 in the olivine ugandite to 55 in the leucitite, with a concomitant decrease in $100 Mg/(Mg+Fe^{2+})$ from 81 to 46.

On the basis of these experiments using olivine ugandite as a model parental composition, we propose that such magmas may be derived by small amounts of partial melting from a 'normal' (non K-enriched) peridotitic mantle source containing H_2O and CO_2 as essential constituents at ≥ 30 kbar and $\geq 1,350^\circ C$. In conditions of crustal warping due to rifting¹⁴, this magma may rise and its temperature decrease, producing a decrease in the solubility of CO_2 relative to H_2O (ref. 15) which suppresses crystallisation of garnet and orthopyroxene. At approximately 20 kbar and $1,200^\circ C$, olivine begins to fractionate, followed by olivine + clinopyroxene at lower pressures and temperatures (Fig. 1b). Residual liquids are depleted in MgO and enriched in TiO_2 , Al_2O_3 , CaO, Na_2O and K_2O . With further decrease in pressure and temperature, this residual liquid incorporates phlogopite which has previously crystallised from one of the liquids derived from the olivine ugandite or, less likely, from the olivine ugandite itself. This phlogopite may crystallise at ≈ 20 kbar (Fig. 1b) and rise by flotation to shallower depths equivalent to pressures of 10–20 kbar. With the addition of phlogopite and further fractionation of olivine and clinopyroxene, liquids substantially enriched in K_2O relative to Na_2O can be evolved at 10–20 kbar and $\geq 1,000^\circ C$. This mechanism of K-enrichment for lavas with $K_2O > Na_2O$ differs from those previously proposed^{6,8–10,16} in that the phlogopite is derived from the parental magma or its derivatives and is not a xenocrystic phase.

We thank the NRC of Canada for financial support, Dr A. R. Wooley (British Museum, Natural History) for a specimen of olivine ugandite and R. L. Barnett, J. Forth and R. Shirran for technical assistance.

Late Precambrian microfossils from Brioverian cherts and limestones of Brittany and Normandy, France

THE discovery of assemblages of unicellular, colonial and multiunit (endosporangium-like) algal microfossils in thin sections and in macerations of carbonaceous cherts and dolomitic limestones from the late Precambrian Brioverian 'Series' of northwestern France is reported here. These assemblages represent new links in the now rapidly expanding known record of Precambrian life. They are of interest because of (1) their similarity to microbiotas of comparable age reported from Canada and Alaska, a similarity suggesting that such assemblages could prove useful for global biostratigraphic correlation of late Precambrian strata; (2) their presence in partially metamorphosed sediments, an occurrence indicating that Precambrian organic-walled microfossils may not be as susceptible

to metamorphic alteration as has widely been assumed; (3) one of the assemblages is preserved in carbonates, a facies previously little studied by Precambrian micropalaeontologists.

Brioverian rocks are of demonstrably Precambrian age: they underlie lavas having a radiometric age of about 550 Myr (ref. 1); in Normandy, they unconformably underlie sediments containing a lower Cambrian fauna, and they are older than intrusive granites dated at about 580–620 Myr (ref. 2). The sequence is apparently substantially younger than 2,000 Myr, the approximate age of the underlying gneissic basement^{3,4}.

In Brittany and Normandy, Brioverian rocks can be subdivided into two age-groups: (1) a lower, metamorphosed sequence which in its upper portions contains metasediments (including black cherts locally known as 'phtanites') and which is older than 695 Myr, the age of plutonic massifs intrusive into the sequence^{2,3}; (2) a younger, unconformably overlying sequence which at its base locally contains volcanic material dated at about 640 Myr (ref. 4) and which is comprised largely of laminated shales and siltstones containing lenses of sandy dolomitic limestone. Three categories of microfossils (types I–III, below) were detected in lower Brioverian black cherts from the Pont–Mazet Quarry, near Quibou (between Coutances and St-Lô), Normandy, and from Le Pelikan (near Lamballe), Brittany; a fourth category (type IV) has been discovered in upper Brioverian dolomitic limestones from Vern-sur-Seiche (near Rennes), Brittany (Fig. 1).

Fig. 1 Sketch map showing distribution of late Precambrian (cross-hatched) and Mesozoic–Cainozoic (stippled) sediments in Brittany and Normandy and locations of fossiliferous lower Brioverian black cherts (1, Le Pelikan, near Lamballe; 3, Pont–Mazet Quarry, near Quibou) and of upper Brioverian dolomitic limestones (2, Vern-sur-Seiche, near Rennes).

Like previously described microfossils from other fine-grained, carbonaceous Precambrian cherts^{5,6}, those of the lower Brioverian cherts have been preserved by siliceous permineralisation in a three-dimensional, structurally little altered condition (Fig. 2a–q). Organic matter comprising these fossils ranges in colour from light-grey to dark-grey or nearly black; like the particulate kerogen that is dispersed throughout these cherts, the carbonaceous microfossils were evidently heated, geochemically altered and 'coalified' during metamorphism of the sedimentary sequence. Microfossils detected in the upper Brioverian dolomitic limestones (Fig. 2r–v) are composed of light- to dark-brown organic matter, are permineralised in carbonate, rather than in silica, and in some cases seem to have been physically disrupted during compaction and diagenesis of the surrounding carbonate matrix (for example, Fig. 2v). These

Fig. 2 Late Precambrian, organically preserved microfossils in thin sections (*a-c, f, i, j, l, p, r, s, v*) and in macerations (*d, e, g, h, k, m-o, q, t, u*) of lower Brioverian black cherts from Pont-Mazet, Normandy (*a-o*) and from Le Pelikan, Brittany (*p, q*), and of upper Brioverian dolomitic limestones from Vern-sur-Seiche, Brittany (*r-v*). Type I microfossils occur singly (*b, d, p, q*), in cell-pairs (*c*) or in irregular colonies (*a*); type II microfossils contain many spore-like coccoids (*e-m*); type III microfossils contain fewer, somewhat larger, spore-like bodies (*n, o*); type IV microfossils occur singly (*t, u*) or in globular colonies (*r, s, v*).

observations, together with studies of the textural relationships between these fossils and their encompassing mineral matrices and the fact that each of the four types of microfossils occurs abundantly (as demonstrated by studies both of acid-resistant macerations and of petrographic thin sections), establish that the Brioverian unicells and colonies are *bona fide* Precambrian fossils: they are indigenous to sediments of established Precambrian age and they were deposited syngenetically with Precambrian sedimentation.

Type I microfossils are spheroidal, thin-walled, unornamented unicells 2–15 μm in diameter (mean diameter = 5.6 μm , $n = 993$; Fig. 3*a*), that occur singly (Fig. 2*b, d, p*), in partially divided cell-pairs (Fig. 2*c*), or in mucilage-ensheathed, irregular colonies composed of a few to hundreds (Fig. 2*a*) of closely packed cells. Such cells comprise about 60% of microfossils detected in the lower Brioverian cherts.

Type II microfossils are spheroidal, noncolonial, multiunit cells, 2–12 μm in diameter (mean diameter = 4.9 μm , $n = 472$; Fig. 3*a*), that contain many spore-like, coccoidal bodies. These internal, closely packed coccoids, which in well-preserved specimens (for example, Fig. 2*e, g*) form three to four contiguous layers or 'shells' concentric about the centre of the spheroids, range in diameter from <0.5 to about 2 μm . A thin, unornamented cell wall can be discerned in those spheroids in which the spore-like coccoids only partially fill the enclosing cell (Fig. 2*h, m*), a condition resulting from degradation of the internal coccoids or, as evidenced by the common occurrence of

solitary, μm -sized, spore-like bodies in the cherts, from the release of such coccoids into the surrounding medium before preservation. Type II microfossils constitute nearly 40% of all forms detected in the lower Brioverian cherts.

Type III microfossils are noncolonial, multiunit, spheroidal cells 7–10 μm in diameter, that enclose two or three concentric 'shells' of closely packed, spore-like bodies (Fig. 2*n, o*). These bodies range in diameter from <2 to ~4 μm ; such cells thus contain fewer, but appreciably larger, coccoidal bodies than those contained in type II microfossils. Type III microfossils comprise only a small portion (<1%) of either of the two assemblages detected in the Brioverian cherts. Cells of this category, and of type II microfossils, are very similar in size to the type I microfossils described above (Fig. 3*a*). Indeed, except for the occurrence of coloniality (exhibited only by type I microfossils) and of distinctive, internal, spore-like bodies (characteristic of types II and III), members of the three categories of microfossils are virtually indistinguishable.

Thus, although additional morphotypes may also be represented, the lower Brioverian 'cherts' from the Pont-Mazet Quarry and Le Pelikan contain at least two morphologically distinct types of unicellular fossils: colonies and (at least in part) solitary type I microfossils; and type II (?) type III + (in part ?) solitary type I microfossils. These Brioverian assemblages bear only limited resemblance to microfloras previously described from late Precambrian cherts of western Europe⁷, for although simple 'type I-like' unicells (for example, *Paleocryptidium cayeuxi*) have been detected in Brioverian black cherts at Lamballe, Brittany⁹, and in late Proterozoic cherts of Bohemia¹⁰, they have not been found in association with the distinctive multiunit microfossils described here. In contrast, however, the Pont-Mazet and Le Pelikan assemblages seem strikingly similar to microfloras recently reported by Moorman from late Precambrian sediments of North America^{11,12}, microbiotas regarded by her as being composed solely of growth stages of a single taxon, *Sphaerocongregus variabilis*, a coccoid blue-green alga somewhat similar to the modern pleurocapsalean *Pleurocapsa fuliginosa*. According to Moorman¹¹, solitary or colonial unicells (as in our type I microfossils) represent vegetative growth stages of *S. variabilis* multiunit cells containing many small, spore-like bodies (as in our type II microfossils) are reproductive endospores, and multiunit cells that contain fewer, larger, coccoids (as in our type III microfossils) are sporangia containing 'nannocytes'. Fossils of the Pont-Mazet Quarry, Le Pelikan and North American assemblages seem virtually identical in morphology; thus, although the Brioverian material does not permit us to substantiate all phases of the "hypothetical growth cycle" proposed by Moorman for *S. variabilis*¹¹ (in particular, we find no evidence of the multiseriate,

Fig. 3 *a*, Size distribution of colonial type I microfossils (---, $n = 260$, measured in thin sections), of solitary type I microfossils (—, $n = 733$, measured in macerations), and of type II microfossils (---, $n = 472$, measured in macerations) from lower Brioverian black cherts of Normandy and Brittany. *b*, Size distribution of type IV microfossils from upper Brioverian limestones of Vern-sur-Seiche, Brittany; histogram shows sizes of solitary cells measured in macerations ($n = 386$); Acol ($n = 29$) and Bcol ($n = 23$) show size ranges for cells in two well-preserved colonies, measured in thin sections.

vegetative, filament-like structures she depicts), these newly discovered assemblages support several of her interpretations. Specifically, it seems increasingly plausible (1) that the multiunit cells may represent reproductive stages, and that the solitary and colonial cells may be vegetative stages of a single taxon; (2) that this taxon is probably of blue-green algal affinity (although its referral to the Pleurocapsales remains in question, as endosporeulation also occurs among chroococcalean and chamaesiphonacean cyanophytes); and (3) that *S. variabilis* was chiefly planktonic, rather than benthonic, in habit (an interpretation supported in both the North American and French material by, among other lines of evidence, the more-or-less random distribution of the fossils within the sediments). In addition, the Brioverian specimens of *Sphaerocongregus*, in which the cells are preserved as organic residues rather than as 'pyritic replacements'¹², confirm that the multiunit cells are authentic microfossils rather than the nonbiological pyrite framboids to which they bear superficial resemblance^{13,14}.

In North America, *S. variabilis* has been detected in shales of the 850–570 Myr-old Hector Formation of the Windermere Supergroup of southwestern Alberta, Canada¹¹, and in carbonaceous shales and mudstones of approximately the same age from the Tindir Group of east-central Alaska, USA¹². Multiunit microfossils similar to the types II and III microfossils described here have also been reported from sediments of the Soviet Union (small-celled species of *Symplastosphaeridium* Timofeev = *Microconcentrica* Naumova) in which they reportedly range in age from the mid-part of the Middle Riphean (about 1,100 Myr in age) into the Late Cambrian¹⁵. Based on these known distributions, and in view of stratigraphical and geochronological data available for the Brioverian sequence, it seems reasonable to suggest that the fossiliferous lower Brioverian phanites at Pont-Mazet and Le Pelikan are probably Middle to Late Riphean (1,100–695 Myr) in age.

Type IV microfossils (Fig. 2*r–v*), detected in upper Brioverian (Vendian age) sandy dolomitic limestones from Vern-sur-Seiche (Fig. 1), are spheroidal, relatively thick-walled (Fig. 2*r, t*), unornamented unicells, 1–20 µm in diameter (mean diameter = 5.9 µm, *n* = 386; Fig. 3*b*), occurring singly (Fig. 2*t, u*) or in globular colonies composed of a few to many cells (Fig. 2*r, s, v*). Colonies range from <30 to >70 µm in diameter and have a measured abundance of about 50 colonies per cm³ of rock; they most commonly occur within (and tend to be orientated parallel to) fine, organic, bedding-plane laminations, a distribution suggesting that they were predominantly benthonic in habit. In size, shape and colonial organisation, type IV fossils bear considerable resemblance to modern, coccoid (for example, chroococcalean) blue-green algae, and the broad size range exhibited by the total assemblage, in comparison with the rather uniform size of member of single colonies (Fig. 2*r, s*; Fig. 3*b*), indicates that several cyanophytic taxa are probably represented. Fossils of this size and organisation have been reported from many Precambrian deposits⁵; the Vern-sur-Seiche assemblage, however, is unusual in that only one¹⁶ other of the nearly four dozen permineralised microbiotas now known from the Precambrian^{5,6} has been discovered in carbonates, the remaining permineralised assemblages occurring exclusively in bedded cherts or in cherty portions of algal stromatolites.

In addition to representing new links in the now rapidly expanding knowledge of Precambrian life, the three microfossil assemblages described here are of interest for the following reasons: (1) two of these assemblages, those occurring in the lower Brioverian phanites, are similar in composition to microfossils of apparently comparable age in North America; taken with other data⁵, these similarities suggest that such assemblages may ultimately provide a reliable basis for global biostratigraphic correlation of Precambrian strata. (2) The occurrence of structurally preserved microorganisms in partially metamorphosed Brioverian cherts seems to indicate that Precambrian organic-walled microfossils may not be as susceptible to metamorphic alteration as has widely been assumed; there is thus good reason for continued palaeobiological and biostratigraphical studies of such facies, especially in western France where many cherts of similar metamorphic grade but of uncertain geological age occur. (3) The occurrence of permineralised, well-preserved microfossils in upper Brioverian limestones suggests that in addition to shales and cherty facies, carbonates represent a productive, but as yet largely untapped, source of new evidence regarding the diversity, evolution and biostratigraphical usefulness of the Precambrian biota.

Samples were collected by J.J.C.; laboratory work at UCLA was supported by grants from the NSF (DEB 77-03888 and DEB 77-22518), from NASA (NGR 05-007-407) and from the University of Rennes.

Influence of a predator on the optimal foraging behaviour of sticklebacks (*Gasterosteus aculeatus* L.)

ACCORDING to the principle of natural selection, each individual animal is assumed to maximise its inclusive fitness¹. Thus, observed behaviour patterns should result from optimisation processes involving costs and benefits measured in a currency of fitness^{2,3}. Certain foraging strategies have been shown to maximise energy intake per unit time^{3–6}. Maximisation of the rate of energy intake, however, is an optimal strategy only if feeding behaviour does not conflict with other needs, such as the detection of predators. If the foraging animal runs a high risk of being preyed upon, the optimal strategy may be a compromise of both needs. A predator's influence on optimal foraging has been dealt with, so far, only in a hypothetical manner^{3,5}. We have investigated this problem experimentally using three-spined sticklebacks (*Gasterosteus aculeatus*) attacking a swarm of water fleas (*Daphnia magna*). We report here that after exposure to a model of an avian predator the sticklebacks' foraging behaviour changes such that they attack swarm regions of lower density which provide a lower feeding rate but should increase their ability to detect an approaching predator. This is predicted by a model using Pontryagin's principle of maximisation.

Sticklebacks first attacked swarm regions of high prey density, but with decreasing attack readiness (for example, induced by decreasing hunger) showed a preference for less dense regions, directing their last attacks at stragglers⁷. A high swarm density

LEADING UK MANUFACTURERS OF

The SCORAH Automatic Electric all glass WATER STILL (patented)

Automatic Can be left on without attention. Heater current cuts off if water supply is interrupted, or inadequate or forgotten. When receiver (5 litres capacity) is full, current cuts off. When distilled water is drawn from receiver, the still resumes operation until receiver is refilled.

Purity Electrostatically charged condenser droplets can pick up fumes, dust and air-borne organisms from the laboratory atmosphere. The design of the receiver vessel ensures absence of such contamination.

Efficiency Heater of Scoraa design and manufacture, consumption 1,700 watts, output 2.4 litres per hour (the full theoretical yield). Cost less than 2p per gallon at 1/2p per unit.

Safety The heating element is out of contact with the feed water, thus eliminating danger from "live" water supply or electrolytic effects of "burn out".

Assembly No retort stands or clamps are required. The 2 1/2-in. diameter ball joint gives a stainless set-up. Outlet cap on boiler for quick periodical drain-off of sediment. The still may be installed on a shelf or platform about 1 ft. above bench level near a sink and enclosed in a transparent plastic cover to keep out dust.

Heat-resisting glass. Interchangeable ground glass joints.

Circle No. 14 on Reader Enquiry Card.

poly-vessels

These expanded polystyrene vessels are used in laboratories and industry for carrying liquid Nitrogen and Dry-Ice. The P.97 size can be used for carrying 'Winchester' bottles of chemicals safely. Supplied with or without carrying handles and lids.

enables the predator to achieve a high feeding rate because of short inter-prey distances. However, at high prey densities the predator has increased difficulty in aiming at individual prey targets^{8,9} ('confusion effect'). Thus it seems likely that feeding in high swarm densities reduces the stickleback's ability to pay attention to other visual stimuli, for example, an approaching predator.

We have developed a model representing the situation of a stickleback confronted with a swarm of water fleas. At any time t its costs in terms of fitness units, result from its hunger state $s(t)$ and confusion while feeding at a capture rate $c(t)$ in a density $d(t)$. The dependence of fitness on hunger state is assumed to be $\alpha s^2(t)$, due to an increased risk of starvation², the costs resulting from confusion are assumed to be $\beta d(t)c^2(t)$, due to a higher vulnerability in the face of predators (greek symbols are used as constants of proportionality to enable adjustment of considered influences). These costs will rise with increasing feeding rate and/or density (our unpublished results). During a given time interval $(0, T)$ the stickleback should minimise its total costs². In other words it will minimise the integral value

$$\int_0^T \alpha s^2(t) + \beta d(t)c^2(t) dt \quad (1)$$

Because the decrease in hunger is proportional to the capture rate we have

$$\frac{ds}{dt} = -\gamma c(t) \quad (2)$$

Capture rate $c(t)$ and density $d(t)$ cannot vary independently, because a high capture rate is impossible at a low prey density. On the other hand $c(t)$ is limited by the minimum time taken to swallow an item of prey; that is

$$(a) \delta c(t) \leq d(t) \quad \text{and} \quad (b) 0 \leq c(t) \leq c_{\max} \quad (3)$$

Therefore the stickleback is able to vary $d(t)$ and $c(t)$ freely in an area under a linear curve reaching a plateau. The predictions deduced from the model will remain true if a dependency similar to Holling's disk equation is assumed. In order to choose the combination of $d(t)$ and $c(t)$ with lowest costs, equality will hold in equation (3a). According to Pontryagin's maximum principle, (1) can be minimised by maximising the hamiltonian¹⁰

$$H(c, t) = -[\alpha s^2(t) + \beta \delta c^3(t) + \gamma c(t)p(t)] \quad (4)$$

with unknown adjoint variable $p(t)$. This gives

$$c(t) = \begin{cases} c_{\max} & p(t) < -\frac{3\beta\delta c_{\max}^2}{\gamma} \\ \sqrt{\frac{\gamma p(t)}{3\beta\delta}} & \text{otherwise;} \\ 0 & p(t) > 0 \end{cases} \quad (5)$$

$d(t) = \delta c(t)$ always.

By solving the system of first order differential equations:

$$\frac{ds}{dt} = -\gamma c(t), \quad \frac{dp}{dt} = 2\alpha s(t) \quad (6)$$

the optimal courses of $s(t)$, and therefore $c(t)$ and $d(t)$, can be calculated. This model leads to the following predictions. First, the stickleback has to start in a high density with a high feeding rate; with decreasing hunger, a lower feeding rate should be achieved with less confusion at a lower prey density (our unpublished results and Fig. 1). Second, if the stickleback's costs of confusion are raised because of a predator presence, a lower capture rate within a lower density will be optimal at the start (Fig. 1). Higher capture rates for some time provide a lower

Fig. 1 Optimal courses of capture rates and densities in time (arbitrary units) for different risks of predation. For clarity the same set of curves indicates both the appropriate capture rates, when read with the left scale, and simultaneously the densities, when read with the scale on the right. The more elevated the risk of predation the lower should be the stickleback's initial capture rate and its aimed density. —, low risk; — — —, medium risk; — · —, high risk.

hunger state after this time. Thus sticklebacks initially feeding faster, will have lower capture rates in lower densities afterwards.

Thus in the presence of a predator a hungry stickleback which would normally attack the most dense region of a swarm with a high feeding rate, has to divide its attention between prey and predator and would be expected especially at the start to slow its feeding rate and to attack a region inducing less confusion, that is, a swarm region of a lower density. These qualitative predictions have been tested by the following experiments.

A tank (25.5 × 12.5 × 17 cm) was divided into halves by a partition which included a sliding door. In front of the back wall of one half of the tank there was a transparent plexiglass cell containing the prey, 9 cm from the sliding door. This cell was divided into seven adjacent compartments, each with a base of 1 × 1 cm. These contained 0, 2, 0, 40, 20, 2, and 0 water fleas of approximately equal size (water level 1.5 cm). To simulate the presence of a stickleback¹¹ predator a black silhouette of a European kingfisher (*Alcedo atthis*, 16 cm beak to tail length) suspended on two nylon threads was made to glide over the other half of the tank (start compartment) at a mean distance of 41 cm and at an angle of 50° subtended horizontally. To ensure that the bird stood out from the 'sky' there was a large white canvas sheet 2 m above the tank illuminated from above by a 500 W bulb. Two alternating experiments (with and without predator) were conducted.

Before each trial three water fleas and then a stickleback which had last fed on the previous day were transferred to the start compartment. In the first experiment after the *Daphnia* had been eaten the silhouette was made to glide over the tank and then the sliding door was opened. In the second experiment the bird was not shown. The initial meal of three *Daphnia* ensured that the stickleback reacted to the cell. All fish passed through the door within five minutes and began biting at the prey-containing cell. Attacks on the prey cell were recorded until there was no bite for at least one min. Each fish was used only once. Mean fish length did not differ significantly between experiments.

The sticklebacks in the presence of the predator (disturbed) hesitated longer between door and first bite (median 10.2 s; quart. 7.1 and 18.8) than those in its absence (undisturbed) (median 6.7 s; quart. 5.2 and 7.7; $P < 0.01$, Mann-Whitney U -test, 2-tailed). The undisturbed fish initially attacked the most dense region whereas the disturbed sticklebacks preferentially the least dense region, that is the stragglers (Fig. 2). In subsequent attacks the disturbed fish continued to prefer the two least dense regions and the stragglers in

Fig. 2 Attacks in relation to swarm density in the presence (black columns) and absence of the predator model (white columns). Parts of columns below bar represent the first half of total number of attacks. $n = 60$; P after Mann-Whitney U -test, 2-tailed; P_F after Freeman-Halton test.

particular. With decreasing attack readiness the undisturbed sticklebacks changed their initial preference for dense regions to a preference for the least dense regions (Fig. 2). During the first ten bites, each region was attacked nearly equally often, during the first half of the total reaction, there was a slight preference for the less dense regions, while the stragglers were strongly preferred in the second half. Overall, the disturbed fish bit less often (26.0 ± 16.8) than the undisturbed ones (49.7 ± 23.1 , $P < 0.0001$, Mann-Whitney U -test, 2-tailed).

The presence of any predator, for example the kingfisher, should distract the fish's attention when detected. Indeed sticklebacks showed a marked fright response to a dark object about the size of a bird moving above them^{12,13}. It seems improbable that the change in the sticklebacks' preference is an epiphenomenon of a more general adaptation to shock, because electric shock increases the sticklebacks' feeding intensity¹⁴, whereas our disturbed fish decrease their feeding intensity. Also in starlings, surveillance diminished their feeding activity¹⁵. There is good reason to believe that a decrease in motivation to bite against the prey cell acts in a similar way on chosen densities and capture rates as a decrease in hunger (our unpublished results). Thus, as proposed by the model, the changed foraging behaviour is an optimal strategy supplying both needs, namely to pay attention to a predator and with the remaining attention to maximise energy intake by attacking a less confusing swarm density.

Effect of reduced litter size on the suckling behaviour of developing rats

DURING the past 20 years considerable attention has been drawn to the effects of altered litter size on the growth and development of various mammals. Studies with rodents have shown that increasing litter size permanently reduces body growth by attenuating the rate of cell division and the final number of cells per organ¹⁻⁵. Conversely, reduction of litter size enhances growth and development^{1,6-9}. Altering litter size has also been shown to effect adult behaviour; by elevating emotional reactivity^{8,12}, and reducing learning ability¹³ in pups raised in large litters, and by reducing emotionality in pups raised in small litters¹⁰⁻¹². It is not known, however, how quickly behavioural differences may result from alterations in litter size. Moreover, it is unclear whether such behavioural effects are a consequence of nutritional changes or of alterations in the pups' developmental experiences. For example, behavioural differences may be due to alterations in maternal behaviour, as rats nursing small litters spend more time in the nest with these pups, and more time handling and manipulating them^{14,15}. Additionally, varying litter size probably alters within litter competition for the nipples, and this may effect behavioural development as well. Utilising recently developed techniques for the measurement of suckling¹⁶⁻¹⁸ and activity¹⁹ we attempted to discover whether altering litter size directly affects the behaviour of pre-weanling rats. We now report that reducing litter size has the surprising effect of reducing both the willingness of pups to suckle and the vigour of their search behaviour on the mother. Moreover, these effects seem more directly linked to alterations in the litter experience than to nutritional differences.

Sprague-Dawley rats were mated and bred in our own colony. Each experimental comparison was made between two litters of pups born within 3 h of each other. In half the replications the pups were randomised between the mothers and culled to produce a normal size litter ($\bar{x} = 12$, range 8-16) and a small litter of three pups. In the other replications the same litter sizes were used but each pup remained with its natural mother. Culling took place on the day of birth, which was considered day

0. Altogether 36 pups raised in litters of three, and 144 pups raised in 12 natural size litters were studied. Half of the litters were tested on day 5, and the remainder on day 10.

Five hours before the start of testing half the pups from the large litter and randomly either 1 or 2 pups from the small litter were removed and placed in an incubator. These pups constituted the deprived groups. Following deprivation each mother was anaesthetised (Chloropent, 2 ml per kg body weight, intraperitoneally, Fort Dodge Laboratories) and laid supine in a clear plexiglas trough. Both deprived and nondeprived pups were placed individually next to the mother and tested for nipple attachment^{17,18}. Numbers of pups attaching and latency scores were recorded. Each pup was tested for 5 min. Pups were tested both on their own mother and the paired complementary mother.

In addition to this suckling test, a second procedure was used¹⁶. In this test each pup was independently held and gently positioned so that its snout came into direct contact with a presuckled nipple. Attachment latencies were recorded, and a 1 min ceiling was used. Previous research has shown that these are both sensitive tests for the appetitive components of suckling, though the former test (pups on mother) requires that the pups locate the nipples while the latter (pups on nipple) does not¹⁸.

Maternally-directed activity was measured using a digital readout vibrational activity monitor¹⁹ modified to record activity only when the pup was in the immediate vicinity (3 cm) of the mother. Each pup was placed on the sensitive surface with its snout in direct contact with its anaesthetised mother. Activity was recorded for 15 s, which was sufficient time for an accurate measurement of maternally-directed exploration, but was too brief to permit the pups to attach to a nipple.

By 10 days of age serious deficits in suckling behaviour were noted in pups raised in small litters (see Fig. 1). Per cent attachment fell from 100% to 50% (deprived) and from 92% to 0% (nondeprived) on the pups on mother test ($z = 4.49$, $P < 0.001$; $z = 5.42$, $P < 0.001$. Test for the significance of the difference between two proportions²⁰). Testing the pups from the small litters on the mother raising the larger litters had absolutely no restorative effects on suckling. This indicates that the deficit is primary to the pups and is not simply due to some inadequacy of their mother as a target stimulus. Furthermore, the deficits were fully apparent when the pups were placed in contact with highly salient nipples; falling from 100% to 30% (deprived $n = 10$), and from 94% to 25% (nondeprived $n = 8$) respectively ($z = 5.43$, $P < 0.001$; $z = 4.61$, $P < 0.001$).

These deficits in nipple attachment were in part mirrored in the activity scores. Normally pups of these ages show an immediate response to anaesthetised mothers, and begin searching the mother's ventrum for nipples. Raising pups in small litters attenuated this behaviour ($F(1,40) = 11.03$, $P < 0.005$; main effect of litter size), though the effect was age dependent, showing up only at day 10 ($F(1,40) = 6.56$, $P < 0.025$; interaction of age $\times$ litter size, day 5: $t(22) = 0.39$, not significant, day 10: $t(22) = 5.80$, $P < 0.001$), and more specifically within the normally very vigorous deprived group ($F(1,40) = 4.24$, $P < 0.05$ interaction of age $\times$ litter size $\times$ deprivation; day 10 deprived: $t(10) = 13.73$, $P < 0.001$, day 10 nondeprived: $t(10) = 2.11$, $P < 0.10$). This observation highlights the fact that the failure of deprived 10-day-old pups to locate and suckle in these test protocols was not just due to an inability to find the nipple (as happens to normal pups on washed mothers²¹) but stems from a general failure to initiate any sort of active search process.

The suckling behaviour of 5-day-old pups however, was less markedly affected by alterations in litter size. Both deprived and nondeprived pups raised in litters of three attached in fewer numbers than normally reared pups when they were required to forage for the nipples of the mothers with which they were reared (deprived: $z = 2.69$, $P < 0.01$; nondeprived: $z = 2.28$, $P < 0.025$). Nondeprived pups also attached in fewer numbers when held in contact with these nipples ($z = 3.58$, $P < 0.001$), although deprived pups attached as readily as controls. Overall,

these deficits in suckling behaviour were less pronounced than those seen on day 10. Moreover, these early deficits were partially ameliorated by testing the pups raised in small litters on mothers raising larger litters, and in most instances significant litter size effects were no longer seen (pups on mother: deprived, $z = 1.21$, not significant; nondeprived $z = 1.49$, not significant; pups on nipple: nondeprived, $z = 2.07$, $P < 0.05$). In short, the suckling behaviour of 5-day-old pups raised in litters of three is slightly abnormal and exacerbated by the apparently poor mammary development of mothers raising these small litters.

We have demonstrated that raising pups in litters of three markedly affects their pre-weaning suckling behaviour. This finding is of particular importance because we are able to detect the litter size effect at such an early age. However, it raises the interesting question of what factors, nutritive or experiential, create these differences in behaviour. Are the deficiencies in nipple attachment of 10-day-old pups raised in small litters due directly to their elevated body weights (29.5% greater than controls) or to certain experiential differences such as reduced competition in the smaller litter? Fortunately, the general facilitatory effect of reduced litter size on body weight and growth was not absolute, but was relative to the body weight of the mother. Thus pups raised in a litter of three with a small mother frequently weighed no more than siblings raised in a litter of 12 with a much heavier mother. This allowed us to separate experiential effects from nutritive effects. In doing so it became clear that litter size *per se* and not body weight was the crucial factor. Pups reared in litters of three with light mothers (who obtain only normal weight levels) clearly manifest the same deficits in nipple attachment as much heavier pups reared in

Fig. 1 Effects of reduced litter size on suckling (pups on mother and pups on nipple test) and maternally-directed activity. Litters were culled and pups cross-fostered on the day of birth to produce both natural ($\bar{x} = 12$ pups) and small (3-pup) litters. Pups were tested at either 5 or 10 days of age. Open columns, litters of 12 tested on mother raising litters of 12; cross-hatched columns, litters of 3 tested on mothers raising litters of 12; solid columns, litters of 3 tested on mothers raising litters of 3.

litters of three with large mothers. The correlations between litter size and attachment latency for both test protocols were very high even when body weight was excluded from the analysis^{22,23} ($r = -0.935$ and -0.732 pups on mother and pups on nipple test respectively, all P -values < 0.001). On the other hand, the correlations between body weight and attachment latencies were insignificant when litter size was excluded ($r = -0.234$ and 0.114 respectively, all P values not significant). This result strongly suggests that the litter size manipulation was not affecting suckling simply through its modulation of food availability and body weight. Rather, some experiential aspect of the situation seems to be influencing the pups behaviour. One possibility is that the reduced level of competition in the small litters was not adequate to maintain performance on these suckling tasks, while an alternative possibility is that pups from small litters are accustomed to, and require, a great degree of maternal stimulation before suckling and fail to suckle anaesthetised mothers who do not provide this stimulation.

Overall, it is apparent that raising pups in litters of three attenuates both the appetitive component of suckling, and the vigour with which these pups search their anaesthetised mothers. These differences were small at day 5 and to a large extent reflected differences between the mothers, more than differences between the pups. By day 10 however, deficits in suckling behaviour were marked, and were primary to the pups. Finally, although rats raised in small litters usually weigh more than siblings raised in larger litters, this increase in body weight was not a necessary condition for the disruption in suckling behaviour. It may seem paradoxical for 10-day-old pups from small litters to weigh more than siblings raised in large litters given their apparent hypomotivational state. However, it must be pointed out that the mother's lactational capacity is clearly the rate limiting factor for weight gain in pre-visual pups raised in large litters^{24,25}. Thus, although these pups may be more vigorous in their suckling behaviour, their body weights are in fact limited by restricted food availability.

This study demonstrates that early experience may have significant effects on the ontogeny of ingestive behaviour. What precisely these experiences are, and whether their effects extend beyond the suckling period, remains to be determined. However, this study clearly indicates that 'nutritional' studies relying on litter size manipulations may be producing effects which are not in fact due primarily to changes in nutrition.

Thermal acclimation in temperate lizards

THERMAL acclimation has been studied most intensively in aquatic ectotherms¹ in which body temperature closely approximates water temperature, which changes slowly with season. As aquatic ectotherms must therefore be active over a range of slowly changing body temperatures, acclimation usually functions as a homeostatic mechanism; following a temperature change in the environment, the organism's metabolic rate is adjusted so that it is returned to near its original level². Some terrestrial animals, particularly reptiles which thermoregulate behaviourally, are subject to considerable daily fluctuations in body temperature³. This difference in the thermal ecology of aquatic ectotherms and terrestrial reptiles, which may cause a difference in the acclimatory responses of the two groups, has not been considered in the work on thermal acclimation in reptiles⁴⁻⁶. Consequently, this work is of little use in predicting the acclimatory responses of reptiles to seasonal temperature changes in the field. We present here evidence that lizards allowed to thermoregulate behaviourally acclimate only at low body temperatures and that the common pattern of acclimation differs from that of aquatic organisms in being determined by requirements of low temperature energy conservation rather than metabolic homeostasis.

Males of four lizard species were used, two from a warm temperature climate (*Podarcis hispanica* and *Psammotriton hispanicus*) and two from a cool temperate climate (*Lacerta vivipara* and *Anguis fragilis*). The experimental design was similar for all species. Lizards were housed in vivaria in a constant temperature room with the temperature adjusted to the mean night time temperature of the season under study. Heat lamps in the vivaria were turned on daily for a period corresponding to the mean photoperiod of the season (Table 1). When allowed access to these lamps, the lizards maintained a relatively constant body temperature which was considerably higher than, and independent of, shade air temperature. At night, with the heat lamps off, the lizards' temperatures fell quickly to ambient. Thus, under these experimental conditions, the lizards were subjected to a fluctuating daily temperature

Table 1 Photoperiod and night time temperature regimes used in the seasonal acclimation study

	Climatic type			
	Warm temperate		Cool temperate*	
	Night time temperature (°C)	Photoperiod (light:dark) (h)	Night time temperature (°C)	Photoperiod (light:dark) (h)
Spring	10	13:11	5	13.75:10.25
Summer	20	14:10	15	15.50:8.50
Autumn	15	11:13	10	10.75:13.25
Winter	5	10:14	—	—

* Cool temperate lizards were studied only in spring, summer and autumn because they are in hibernation, and therefore not exposed to a fluctuating temperature regime, in winter.

regime similar to that experienced under natural conditions. All animals were maintained in this way for at least a month before measurements of metabolic rate were made. Metabolic rate was measured as the rate of oxygen consumption of lizards in small constant pressure respirometers immersed in a constant temperature water bath. All measurements were made on quiescent, post-absorptive animals and therefore approximate to standard metabolic rate. Oxygen consumption rates were measured at 5 degree intervals from 5 °C (the lowest temperature experienced by any animal under the experimental regime) to 30 or 35 °C (the upper body temperatures attained when the heat lamps were on⁷).

For each species, seasonal acclimation had little or no effect on rates of oxygen consumption at the higher temperatures, although significant differences between seasonal groups occur at the lower temperatures for all species (Fig. 1). In other words, differences in metabolic rate do not generally occur when oxygen consumption is measured at temperatures experienced by all groups every day; it is only at temperatures experienced by some seasonal groups but not by others (the lower temperatures) that differences in metabolic rate occur. These seasonal differences in low temperature metabolic rate can be interpreted as mechanisms for energy conservation. In *Podarcis hispanica*

and *Psammodromus hispanicus* (Fig. 1a, b) low temperature metabolic rates are lowest in winter and spring. In the region where these lizards originate, it is at these seasons that there are the longest periods of adverse weather when the lizards cannot come out to bask and feed. In *Lacerta vivipara* and *Anguis fragilis* (Fig. 1c, d) low temperature respiration is less in autumn than in spring or summer; this is possibly a mechanism for reducing low temperature energy expenditure in cool temperate animals entering or about to enter hibernation.

As many reptiles utilise solar radiation to maintain high, relatively constant body temperatures^{8,9}, it is not surprising that little or no thermal acclimation occurs at high temperatures because such body temperatures can be attained each day that the sun shines. To the animal, the main thermal difference between the seasons is the temperature to which its body drops at night, and it is at these low temperatures that seasonal differences in metabolic rate (acclimation) occur. The animal is incapable of feeding at these low body temperatures and it is therefore energetically efficient to effect some measure of energy conservation when the animal has to spend long periods at low temperatures. Thus the common pattern of acclimation in temperate reptiles is determined by considerations of low temperature energy conservation. Some other terrestrial ectotherms also thermoregulate behaviourally¹⁰⁻¹² and it is possible that this pattern of acclimation is widespread in terrestrial animals.

Feeding, blood glucose and plasma insulin of mice at dusk

MOST omnivorous species exhibit a circadian rhythm of food intake. During one part of the day food is consumed at a rate in excess of immediate metabolic needs, and the surplus is stored to support metabolism for the remainder. Le Magnen and Devos¹, for example, have shown a predominance of lipogenesis in the night-time feeding period of the rat, and pronounced lipolysis during the day, when little food is consumed. A variety of metabolic adaptations exists to match this discontinuous pattern of food intake with relatively constant metabolic use of nutrient², but the question remains whether the hyperphagia at one time of day produces these changes or is a consequence of them. Le Magnen suggests the latter³, at least in the case of increased night-time meal frequency, and in models of feeding, such as that of Toates and Booth⁴, an increased rate of metabolic

clearance of food at night is a considerable factor in promoting increased food intake. On the other hand, eating at a high rate clearly will promote metabolic changes, as bunching of the normal daily intake into a very short period will lead to increased weight gain⁵. A compromise possibility is that a greatly increased rate of feeding at dusk rapidly promotes metabolic changes subsequently favouring a high rate of feeding in the ways suggested by previous authors. The results reported here suggest that such a mechanism may operate in the feeding of mice, in that a great increase in feeding rate around the onset of darkness produces changes in carbohydrate metabolism which may both favour storage of energy and tend to increase subsequent food intake.

All experiments used individually caged female C57 mice, ~100 d old at the start of the experiments, and kept for their entire lives in a temperature-controlled room ($23 \pm 1^\circ\text{C}$), on a constant 12-h light, 12-h dark cycle (lights off 13.00). Unless stated otherwise, standard laboratory food (Spratts rodent breeding diet) and water were available *ad libitum*. Food intake was measured where necessary by regularly weighing feeder inserts in the cages⁶. Blood samples were withdrawn from a tail vein within 2 min of removal from home cage (this technique yields assay results indistinguishable from blood obtained by immediate decapitation). Glucose was assayed in duplicate 100-

Fig. 1 Effects of food restriction on blood glucose (a) and insulin levels (b) at dusk. In the control group (circles), blood glucose falls and blood insulin rises significantly at dusk ($P < 0.01$ in each case, *t*-test with 14 d.f.). There is no significant change in either variable (squares on each graph) if food intake is restricted ($P > 0.1$ in each case, *t*-test with 14 d.f.).

Fig. 2 Effects of combinations of meals on blood glucose and insulin levels. Each graph shows blood glucose (circles) and insulin (squares) levels at 15-min intervals after one (a), two (b) or three (c) meals taken at regular intervals around dusk. Each glucose point is the mean of 12 observations and each insulin the mean of 8. Glucose levels rise significantly only after one meal ($P < 0.01$, *t*-test 22 d.f.), and fall significantly after the third ($P < 0.01$, *t*-test 22 d.f.). Blood insulin levels rise significantly after all combinations of meals, although the magnitude of the rise clearly varies ($P < 0.01$, *t*-test with 14 d.f. in each case).

μl samples of whole blood, using a standard glucose oxidase technique (Glucostat, Worthington). Insulin was measured by radioimmunoassay, again using a standard kit (Radiochemical Amersham), on duplicate 100- μl samples of plasma. A human insulin standard was used, but as all conclusions are drawn from comparisons of insulin levels in different groups of animals, any slight systematic error thereby introduced will not affect their validity. In any one experiment each animal was bled only once, and at least 3 weeks passed between successive bleedings of the same individual, none of which were bled more than three times.

In the first study, the hourly rate of food intake of mice was measured for a few hours before and after dusk, and blood samples were removed at regular intervals for assay. Second, a group of mice were fed normally until 1 h before dusk, and thereafter restricted to their afternoon rate of feeding. Blood glucose and insulin levels sampled at regular intervals were compared with a control group allowed *ad libitum* access to food.

Mice normally eat in meals^{6,7}, and in the final experiment the normal dusk pattern of meal taking was mimicked to examine its metabolic consequence. Mice were allowed *ad libitum* food and water until 2 h before dusk, after which food was removed.

Starting 90 min later, groups of animals were given one, two or three 'meals' by allowing 10-min periods of access to food, separated by 20 min. Animals were observed to eat about the same amount in each period, and the 5% of animals who failed to eat in any or all of the periods were discarded. Blood samples were taken from groups of animals at 15-min intervals after their last meal.

There is a fivefold increase in the hourly rate of feeding at dusk. ($P < 0.001$ t -test with 31 d.f.), and this is closely associated with a fall in blood glucose ($P < 0.01$ t -test with 34 d.f.) and a rise in blood insulin ($P < 0.01$ t -test 14 d.f.). As the rate of feeding subsequently declines, these changes are reversed. If food intake is restricted (Fig. 1), blood glucose levels do not fall, and insulin levels do not rise. In the third experiment, the three 'meals' had quite different consequences. Figure 2 shows that the first meal promotes a rise in blood glucose, with little secretion of insulin, the second a further rise in glucose with a considerable rise in insulin, and the third very high insulin levels, associated with a fall in blood glucose. Insulin levels, however, fall more rapidly after the third meal than after the previous two.

Around dusk, therefore, the rate of insulin secretion in these animals increases to an extent sufficient to depress blood glucose levels in spite of a high rate of feeding. This increase could be due either to some endogenous rhythm of pancreatic activity, or to some direct or indirect effect of the sudden increase in feeding. The disappearance of the changes when food intake is restricted would favour the latter explanation. The high rate of feeding is known⁶ to be due to a very high meal frequency (three per hour), and the final experiment shows that during a series of meals very similar to that taken spontaneously by free-feeding animals, there is a transition between the day-time pattern of elevated glucose with relatively little insulin secretion to the night-time pattern of high insulin secretion, high rate of metabolic clearance of glucose, and presumably storage of energy. The voluntary pattern of feeding adopted by mice at dusk therefore seems to promote metabolic changes leading to more rapid clearance of a meal, which may, as suggested by Le Magnen, and Toates and Booth, facilitate a greater rate of food consumption by shortening the interval between subsequent meals, thus forming a type of metabolic 'positive feedback' of feeding upon itself. There are several, as yet inseparable, ways in which this might occur. Clearly, the activity of eating frequently, the operation of the gut receiving meals in rapid succession, or the metabolic effects of feeding at a high rate provide some additional stimulus to the pancreas, leading to a higher rate of insulin secretion at a given blood glucose level. The pancreatic islets are known to be influenced by both the nervous system and the gut hormones, so that either or both may contribute to the effect⁸.

If such a positive feedback could be shown to operate in other species, such as our own, then its inappropriate activation by frequent voluntary consumption at high rates may facilitate excessive weight gain.

Cardioactive substances in the monarch butterfly and *Euploea core* reared on leaf-free artificial diet

THE monarch butterfly (*Danaus plexippus*) is one of the best known species which sequester and store cardiac glycosides¹⁻³ obtained directly from their larval food plants. On the other hand *Euploea core*, a related Danaid species feeding on the same family, Asclepiadaceae, is a poor storer of these substances⁴. Cardenolides are absent if the butterflies are reared on plants which do not contain them, and, in the past, all cardioactivity in the insects' body tissues has been attributed to dietary cardenolides. We now report that extracts of both larva and pupa reared on a leaf-free artificial diet⁵ proved cardioactive, slowing the action of an isolated rat heart (Langendorff preparation)⁶ and increasing the amplitude of contraction.

Specimens were extracted by grinding in a mortar with saline. The volume of saline varied depending on the weight of material, and, where possible, volumes were adjusted to give the same proportion of material to saline. The extraction mixture was centrifuged and 0.1-ml aliquots of this supernatant were injected into the perfusion feed line of the isolated rat heart (Langendorff) preparation. The number of hearts used and the weight of material extracted per 0.1 ml of saline are indicated in Table 1. The maximum change in amplitude of contraction is expressed as a percentage of the control value, and the heart rate was measured over 10-30 s after injection and is also expressed as a percentage of control values.

The emetic effect of mascerated specimens and extracts of *D. plexippus* (at all stages of the life cycle) when fed to pigeons is well known^{2,3,7}. The sensitivity of this test is greater than that of the isolated rat heart, as the presence of small amounts of cardiac glycosides in a butterfly extract can produce delayed emesis when administered to the pigeon, although no response may be observed when the same extract is applied to the rat heart⁸.

Extracts of larvae of *D. plexippus* reared on *Asclepias curassavica* produced an effect typical of cardiac glycosides (Table 1 and Fig. 1b), that is, a marked increase in the strength of contraction, seen most clearly in the latter half of the trace. Note that the drop in heart rate, although associated with cardenolide action, is also reminiscent of the effect of potassium ions which may have been present in the extracts, or could equally be due to

Fig. 1 a, Effect of artificial diet-reared *D. plexippus* larval extract on the rate and strength of contraction of the isolated rat heart (each vertical trace represents one heart beat). b, Effect of *A. curassavica*-fed *D. plexippus* larval extract on the isolated rat heart. c, Effect of *A. curassavica* extract on the isolated rat heart. On each figure the horizontal line indicates 10 s (this is omitted in Fig. 2b); extracts were given at the beginning of the 10-s period.

Table 1 Assay of larvae and pupae of *D. plexippus* on the rat heart

		No. of experiments	Average weight of material extracted (mg)	No. of insects extracted	% Change in Rate Amplitude	
Artificial diet fed	Larvae (2nd instar)	2	283	7	-78	+67
	Larvae (4th instar)	2	249	7	-66	+56
<i>Asclepias</i> fed	Larvae (2nd instar)	1	283	5	-97	+119
	Larvae (4th instar)	1	249	5	-98	+127
<i>Asclepias</i> fed	Pupae	2	161	2	-79	+84

Larvae were starved for 24 h before testing. Diet-reared malformed pupae did not produce emesis when fed to the pigeon whereas pupae reared on *Asclepias* did³.

the insect's own secretions. Figure 1c shows that the extract of the food plant produces a qualitatively similar effect. Comparison of this with Fig. 2c, produced by an extract from a cardenolide-free *Asclepiad* plant, *Marsdenia erecta*, shows that the latter had no discernible effect on the isolated rat heart. The same negative result was obtained with extracts from the cardenolide-free artificial diet. In contrast, extracts of larvae of both *D. plexippus* (Fig. 1a) and *E. core* (Fig. 2a) reared on the artificial diet, showed cardio-activity. The same effect was produced by extracts of the latter species reared on *Marsdenia* (Fig. 2b). However, the relatively brief slowing of the heart rate and increase in contraction are not typical of the cardenolide response elicited by *Asclepias*-reared material.

For comparison, we tested *Tyria jacobaeae*, an aposematic moth, highly repellent to vertebrate predators^{9,10}, containing large concentrations of pyrrolizidine alkaloids which it sequesters from its food plant¹¹. Neither pupa (Fig. 2d) nor foliage of the food plant on which it was reared (*Senecio jacobaeae*) produced any marked action on the rat heart.

It is unlikely that the cardioactive substance produced by *D. plexippus* is a cardenolide, despite its action on the isolated heart and the fact that some insects are known to secrete them¹², for Roeske *et al.* found no cardiac glycosides in this species reared on plants such as *Gonolobus rostratus* and *A. amplexicanlis*², which lack such substances. They did not, of course, test their

specimens for other cardio-active substances, which we can, nevertheless, assume were present. Furthermore, a substance with a very similar effect, found in *Ipomoea batatas*, and also present in the butterfly *Hypolimnas bolina* fed on it⁴, was demonstrated by Reichstein (in Dixon *et al.*)³ not to be a cardenolide.

Most highly coloured insects possess more than one chemical deterrent¹³, frequently a combination of both a primary self-secreted or self-manufactured substance, and a secondary, superimposed, plant-sequestered toxin. Such a primary defence must be particularly important in the case of *D. plexippus*, as the cardenolides which it sequesters and stores, and which so far have been considered by many workers to be its only defence mechanism, are frequently lacking in the foliage of its favourite food plants such as *A. syriaca*¹⁴. Thus, a self-secreted cardio-active substance, even though non-emetic, will make the population much less dependent on the variation and fluctuations characteristic of the secondary plant substances.

Experiments are in progress with various predators and live Danais reared on an artificial diet. It is essential to use fresh material in these feeding experiments, as, unlike the secondary plant substances, the majority of toxic self-secretions of Lepidoptera are lost or destroyed¹⁵ by storage.

The relationship between tonicity and flagellar length

THE manner in which a cell regulates the size and number of its organelles is not fully understood. We have studied the regulation of flagellar length. Flagella are organelles involved in cellular motility and sensory transduction¹, and in standardised conditions, the flagella of a given species are constant in length and number. Thus, taxonomists include these characteristics in species descriptions². The organism we are investigating is the unicellular biflagellate green alga *Chlamydomonas reinhardtii*, in which the two flagella are of equal length². If the flagella of *Chlamydomonas* are amputated, they regenerate to their original length in approximately 90 min (ref. 3). If only one flagellum is removed the remaining organelle shrinks while the new flagellum is elongating, until both are of the same length. At this point both organelles proceed to elongate, stopping when the normal length is reached^{3,4}. Resorption of organelles containing microtubules has been shown to occur under a number of conditions in different organisms⁵. Recently it has been shown that the flagella of *Chlamydomonas* can be caused to shorten by a variety of agents such as pyrophosphate⁶⁻⁸, chelators⁶, halothane⁹ and other salt solutions^{6,10,11}. This large variety of substances led us to study the effects of tonicity, *per se*, on flagellar length.

To determine what effect osmotic pressure has on flagellar length, vegetative cells of *Chlamydomonas reinhardtii* were incubated in two salt solutions: sodium chloride and sodium pyrophosphate, and two sugar solutions: mannitol and sucrose, all at a tonicity approximately three times that of normal growth media. Figure 1 shows that the flagella shorten to almost half their original length during the first 60 min, regardless of the solution used to alter the tonicity. Furthermore, the rate of shortening is similar in all cases. Since the only similarity between the various solutions is tonicity (not molarity), we attribute the shortening to the increased osmotic pressure.

After 60 min the flagella of cells which are in salt continue to shorten, until a steady state is reached. However, the flagella of cells which are in sugar begin to regrow, reaching near normal lengths after six h. This regrowth of flagella in the sugar can be prevented by placing the cells in the dark (data not shown). This phenomenon is under investigation.

For any given solution, the length of the flagella, at 60 min, appears to be inversely related to the tonicity of the surrounding medium. This is shown in Fig. 2a and b. Figure 2a presents data for NaCl at various tonicities and Fig. 2b presents data for sucrose at different tonicities.

The experiments in Figs 1 and 2 were of short duration (6 h), and it was of interest to determine if in continuous culture in salt solutions of different tonicities, the cells would adapt to the increased osmotic pressure and possess flagella of normal

Fig. 1 Change in flagellar length at increased osmotic pressure. Vegetative cells of *Chlamydomonas reinhardtii* were grown on a 12 h light–12 h dark cycle as previously described^{1,12,13}. An equal volume of a cell suspension at a concentration of 3×10^7 cells per ml were mixed with solutions of either mannitol, sucrose, sodium chloride or sodium pyrophosphate (made up in growth media with the pH adjusted to 7.0). At timed intervals thereafter, aliquots of the cellular suspension were removed, fixed with 2.5% glutaraldehyde and flagellar lengths measured as previously described¹³. In addition, aliquots were centrifuged to remove the cells and the osmotic pressure of the supernatant was measured on a model 5100 vapour pressure osmometer (Wescor). □ Mannitol (260 mOsm kg⁻¹; 0.25 M); ● sucrose (235 mOsm kg⁻¹; 0.2 M); ▲ sodium chloride (240 mOsm kg⁻¹; 0.125 M); ■ sodium pyrophosphate (257 mOsm kg⁻¹; 0.05 M); △, normal growth medium (81 mOsm kg⁻¹).

length. The data presented in Table 1 show that the flagella of cells grown for 2 weeks in various NaCl concentrations were shorter than normal, and the higher the salt concentration, the shorter the flagella. It should be noted that at higher salt concentrations (0.1 M and higher) the rate of cell division was partially inhibited, indicating a stress condition. Thus, flagellar length might be an indicator of osmotic stress on the cells. Furthermore, the short flagella at higher salt concentrations were not a result of mutant selection, since cells washed free of salt regenerated longer flagella (data not shown).

The evidence presented here indicates that the flagella of *Chlamydomonas reinhardtii* respond to changes in osmotic pressure. Higher osmotic pressures (increased by either salt or sugar) causes shortening of the flagella. Thus we conclude that flagellar length is, in part, controlled by the osmotic pressure of the medium. This conclusion is further substantiated by the work of Telser⁹, in which flagella of *Chlamydomonas reinhardtii* were observed to elongate when the cells were placed in distilled water. We have repeated those experiments with similar results. Also, increased osmotic pressure has been shown to lead to the stoppage of the ciliary beat and ultrastructural changes in the cytosol of mussel gill cilia¹⁴. We speculate that some of the flagellar length mutants of *Chlamydomonas reinhardtii*^{15,16} might be osmoregulatory mutants; the cells may be altered in their ability to osmoregulate and therefore have shorter or longer flagella than normal.

We do not yet know the mechanism of shortening due to increased osmotic pressure. One possibility is the action of high tonicities on the microtubules forming the axoneme of the flagella. Protein turnover has been demonstrated in full length flagella, and it appears that the organelle is maintained in a state of dynamic equilibrium¹⁷⁻¹⁹. The loss of water from the cells (due to the osmotic stress) could change the concentrations of solutes in the cell and flagella, which, in turn, would alter the polymerisation and depolymerisation of microtubules.

The regulation of the length of flagella is obviously under the control of complex metabolic processes. Osmotic pressure seems to be an environmental factor which can influence those processes. However, not all flagellar shortenings are due to osmotic effects. Drugs, such as halothane⁹ and herbicides such as amiprophosmethyl⁶ probably cause flagellar shortening by

Table 1 Flagellar length of cells grown in various salt concentrations

Salt concentration (osmolarity)	Flagellar length (µm)	Per cent reduction in flagellar length
Normal medium (81)	13.3	—
0.02 M (90)	6.5	51
0.05 M (116)	4.4	67
0.1 M (196)	1.2	91

Flasks containing 50 ml of culture media, at various salt concentrations, were inoculated with 2×10^6 cells and placed to grow on a 12 h light–12 h dark cycle. After two weeks samples were removed, fixed with glutaraldehyde and flagellar lengths measured as in Fig. 1. Osmolarities were measured as in Fig. 1.

Fig. 2 Change in flagellar length in solutions of different osmolarities. Conditions of cell growth and experimental procedure were the same as in Fig. 1. *a*, Changes in flagellar length in sodium chloride solutions of various osmolarities: Δ , 163 mOsm kg⁻¹ (0.075 M); $\square$, 221 mOsm kg⁻¹ (0.1 M); $\blacktriangle$, 256 mOsm kg⁻¹ (0.125 M). *b* shows changes in flagellar length in sucrose solutions of various osmolarities: Δ , 153 mOsm kg⁻¹ (0.125 M); $\square$, 193 mOsm kg⁻¹ (0.175 M); $\blacktriangle$, 229 mOsm kg⁻¹ (0.2 M). Normal growth medium has an osmolarity of 81 mOsm kg⁻¹. The molarities of the solutions given above are in addition to normal medium.

specific chemical action. Innate cellular properties are also involved in control of flagellar length as illustrated by the alga *Euglena gracilis* which has two flagella of unequal length²⁰.

Our results are significant not only to the cell biologist interested in the physiology of the flagellum, but are also directly related to algal classification, where flagellar length is often included as a species characterisation². Attention should be paid to the salinity of the environment when comparisons are made of flagellar lengths of presumed different species.

After submission of this manuscript a paper which dealt with flagella shortening in *Chlamydomonas* was published²¹. It was reported that 150 mM NaCl caused shortening of flagella while equimolar KCl did not. Our unpublished results show that equimolar KCl will cause flagella to shorten. However, the flagella re-elongate (as in the presence of sugar) and by 90 min (the time at which flagella were measured by Quader *et al.*²¹) the flagella are of normal length. In addition we find that during re-elongation of flagella in the presence of sugar there is a simultaneous accumulation of potassium by the cells. The relationship of potassium to flagellar re-elongation is under study.

We thank Dr Aletha Solter for critical reading of the manuscript and Darryl Ray and Drs L. Wilson, R. Trench, P. Laris, D. Morse and N. Sharon for their comments. This work was supported by NSF grant PCM 77-07380.

Degenerating nerve products affect innervated muscle fibres

THE main factor controlling mammalian muscle fibre membrane characteristics is the fibre's activity^{1,2}. Other influences may be a trophic factor³⁻⁵, and a loosely termed 'inflammatory effect'^{1,6}. The latter effect is unspecific, appearing when a thread or degenerating nerve is placed over the muscle⁶, after operative procedures near the muscle (ref. 2 and our unpublished observations) and after axonal degeneration within the muscle's own nerve^{1,7,8}. This inflammatory effect may underlie the observations of Cangiano and Lutzemberger⁷ that the innervated fibres in a partially denervated muscle show certain membrane changes similar to those seen on inactive muscle fibres. Such surface changes in inactive muscles have been implicated as the cause of α motoneuronal terminal sprouting⁹, and that they may also occur on innervated fibres in partially denervated muscles provides an explanation for the occurrence of terminal sprouting here too without invoking additional mechanisms. However Cangiano and Lutzemberger's results have been disputed¹⁰. We now report an experiment which demonstrates that degenerating nerve fibres can affect innervated muscle fibres, and that this interaction may well stimulate motoneuronal terminal sprouting.

We produced muscles with afferent nerve fibre degeneration but with normal efferent innervation by cutting the dorsal roots supplying the muscles, peripheral to the dorsal root ganglia. We used the soleus and peroneus tertius muscles of mice weighing 30 g or more. Under chloral hydrate anaesthesia (0.2 ml of 3.5% solution per 10 g body weight) the L4 and L5 spinal foraminae were exposed and as much of the dorsal root ganglia as possible removed, care being taken to avoid damaging the ventral roots. Five to eight days later (when any inflammatory effect should be present¹) the acute experiment was performed, the muscles being examined *in vitro* using methods described previously¹¹. We confirmed the absence of motor denervation by comparing the nerve and directly evoked twitch and 50 Hz, tetanic tensions. We also counted the number of motor units in the muscle using carefully graded stimuli to the nerve and compared this total with that obtained from contralateral control muscles. Muscles with any indication of motoneurone death were discarded (8 muscles from 38 operations). A muscle's acetylcholine sensitivity was taken as the size of its contracture in 5×10^{-4} g ml⁻¹ acetylcholine perchlorate, expressed as a percentage of its maximum directly evoked 50 Hz tetanus. The muscles with their nerves were stained in zinc iodide and osmium tetroxide, and the amounts of degeneration within the nerve, de-afferented muscle spindles, and motoneuronal sprouting were determined.

Controls consisted of the normal contralateral muscles from experimental animals, and also muscles from mice with dorsal roots cut central to the ganglion and hence with intact afferent axons (rhizotomy). This latter group controls for the effects of removing some afferent input to the spinal cord on muscle activity, and also for any effects of nerve degeneration within the spinal cord.

Fig. 1 Histograms of the acetylcholine sensitivities of the various groups of muscles. The rhizotomised solei (*b*) are not significantly different from the normal control muscles (*a*). However, the ganglionectomised solei (*c*) are significantly different from normal muscles ($P < 0.001$ Mann-Whitney *U* test), and significantly different from the rhizotomised control muscles ($P < 0.025$). The rhizotomised peronei are significantly different from normal controls ($P < 0.05$); as are the ganglionectomised peronei ($P < 0.01$). The two operative procedures do not produce significantly different acetylcholine sensitivities in this muscle, although the mean sensitivity is higher in the ganglionectomies (10 ± 0.5 , $n = 15$ compared with 7 ± 1.6 , $n = 10$). The black portions on the histograms are the results from muscles where more than 40% of the spindles were de-afferented.

Figure 1 shows the acetylcholine sensitivity of the three groups of muscles. The ganglionectomised solei are significantly more sensitive than either of the control groups ($P < 0.025$, Mann-Whitney *U* test), which are not significantly different from one another. Both the ganglionectomised and rhizotomised peronei are significantly more sensitive than the control normal muscles ($P < 0.01$ and $P < 0.05$, Mann-Whitney *U* tests). In this muscle the two operations do not produce significantly different effects, though ganglionectomy does produce the higher mean sensitivity (10 ± 0.5 , $n = 15$ compared with 7 ± 1.6 , $n = 10$, mean $\pm$ s.e.m.). Figure 2*a* shows a scattergram of the relationship between the acetylcholine sensitivity and the amount of de-afferentation within soleus. The correlation ($r_s = 0.525$) is significant ($P < 0.05$). Thus, particularly in the soleus, nerve degeneration products do seem to cause innervated muscle fibres to become acetylcholine sensitive.

Examination of the α -motoneurone terminals in experimental muscles reveals terminal sprouting. Figure 2*b* is a scattergram of the relationship between terminal sprouting and de-afferentation in soleus, and there is a significant correlation ($r_s = 0.453$, $P < 0.05$). The percentage of terminals with sprouts was 17 ± 5.6 , $n = 16$ in ganglionectomised solei, 6 ± 1.0 , $n = 9$ in rhizotomised solei and 7 ± 2.8 , $n = 10$ in normal solei.

These results support the suggestion that muscle fibre surface changes are a local stimulus to terminal sprouting⁹, and agree with the results of other experiments¹². However, we cannot rule out the possibility that some feature of degenerating nerves might act directly on intact nerve fibres to stimulate terminal sprouting, as seems to be the case for collateral or nodal sprouting¹³. We do in fact see some collateral sprouting in the

intramuscular nerve branches of these de-afferented preparations.

Extensive de-afferentation is required to give significant increases in acetylcholine sensitivity (Fig. 2*a*) and it is only in such muscles that we see much sprouting (Fig. 2*b*). However, it is well known that relatively small amounts of partial motor denervation are sufficient to produce large increases in sprouting. In fact, removing only one or two motor units from soleus by selective ventral root damage can produce up to 60% terminal sprouting (data not shown). This might suggest that muscle fibres or motoneurons are especially responsive to motoneurone degeneration. A simpler explanation is that motoneurons arborise profusely within a muscle and pass close to one another's endplates, unlike afferent fibres which do not branch much nor run through the endplate zone. Consequently a single degenerating efferent fibre may produce larger amounts of active substances closer to their sites of action than a single degenerating afferent. A third possible explanation for the apparently greater amount of sprouting after ventral root damage is that denervated muscle fibres might liberate a sprouting agent which could spread through the muscle. This seems unlikely, because in a muscle where transmission is partially blocked, sprouting occurs only from the blocked terminals⁹. If the inactive and hence altered muscle fibres liberated diffusible chemicals which could elicit sprouting then one might expect unblocked terminals to sprout also.

Fig. 2 *a*, A scattergram of the relationship between acetylcholine sensitivity of solei and the amount of de-afferentation produced in ganglionectomised preparations, r_s (Spearman rank correlation coefficient) = 0.525, which is significant ($P < 0.05$). The degree of de-afferentation was assessed by counting the number of deafferented muscle spindles and expressing this as a percentage of the total number of spindles in that muscle. A normal soleus has 6–8 spindles. Obviously this may only be a rough estimate of the total amount of de-afferentation. This graph demonstrates that large amounts of de-afferentation must be produced to have much effect on the muscle's acetylcholine sensitivity, and this may explain the small size of the differences seen in Fig. 1. Especially in the earlier experiments, in trying to avoid ventral root damage the surgery was over cautious and removed rather little of the ganglia. Histologically, only small amounts of degeneration were seen, and the proportion of de-afferented spindles was small. This problem was particularly acute in the peroneus, because this muscle appears to receive the bulk of its afferents through L5, and this ganglion being harder to remove is usually less damaged. The result was that fewer than half the peronei had any completely de-afferented spindles. Considering only the black squares in Fig. 1 (de-afferentation > 40%), the effect of ganglionectomy is quite obvious. (The rhizotomy operation is relatively easy, and always destroys 100% of the limb's afferent input to the spinal cord.) The particularly small effect of ganglionectomy in peroneus might also be because it contains 'fast' motor units. It has been shown that a fast pattern of muscle activity is particularly effective in inhibiting the development of acetylcholine supersensitivity¹. *b*, A scattergram of the relationship between terminal sprouting and de-afferentation. There is a significant correlation ($r_s = 0.453$, $P < 0.05$). There is also a significant correlation between the amount of sprouting and the acetylcholine sensitivity of the muscle ($r_s = 0.523$, $P < 0.05$), as is found in certain other circumstances in which sprouting occurs^{9,12}.

Finally, in order to unravel complex innervation patterns (for example, those of the muscle spindle), it is common to use de-afferented or de-efferented preparations. Our experiments have shown that de-afferentation causes efferent sprouting; clearly this may produce misleading descriptions of the normal pattern of innervation in such preparations. Perhaps this explains some of the controversy¹⁴ over the innervation of the muscle spindle.

Adjuvant-induced thymus-derived suppressor cells of cell-mediated tumour immunity

THE use of immunoadjuvants in enhancing immune responses to various antigens and particularly in tumour therapy is based largely on the concept that an increased level of specific immunity may be achieved by nonspecific stimulation of the immune system¹. However, the tumour-protective effect of adjuvants has not been entirely consistent in all systems studied, and also, an immune suppressive effect of adjuvants has been demonstrated mainly by using *in vitro* assays of cell-mediated immunity². It remains to be determined whether a defect measured by such general tests of lymphocyte function may also represent an indication of depressed cell-mediated immunity against the progressive growth of tumours. Moreover, the target cell in the immune system for adjuvant effect has not been characterised clearly. Our laboratory has made extensive study of immune response to SV40-induced syngeneic transplantable MKSA cells of BALB/c mice³⁻⁵. This tumour has been shown to possess tumour-associated antigens which can immunise specifically against the growth of MKSA cells. The role of T lymphocytes in the immune response against SV40-induced tumour-associated antigens was shown by *in vivo* tumour cell neutralisation assay (Winn)⁶ and by *in vitro* ⁵¹Cr release assay⁷. We now report that injection of complete Freund's adjuvant (CFA), one of the most useful adjuvants in enhancing immune responses, markedly inhibited the ability of immune spleen cells to prevent SV40-induced tumour growth in the Winn assay and to lyse SV40-transformed cells in the cytotoxicity assay. Moreover, untreated mice which reject suboptimal numbers of tumour cells die of progressive tumour growth following treatment with CFA and tumour cells; adult thymectomy reverses the suppression caused by CFA; and the target cell for CFA effect is the T lymphocyte. These data suggest that treatment

Table 1 The effect of CFA on growth of SV40-induced tumour and on cell-mediated cytotoxicity against SV40-transformed cells

Treatment	Challenge with MKSA cells* (dead/total)	Neutralisation of MKSA cells† (dead/total)	% Cytotoxicity against C57SV cells‡
None	0/10	0/10	39.2
CFA	9/10	10/10	2.3

This is a representative experiment out of five experiments with similar results.

* CBF₁ mice were inoculated s.c. with 2 × 10⁷ C57SV cells. After 15 d the animals were challenged s.c. with 1 × 10⁵ MKSA cells.

† CBF₁ mice were inoculated s.c. with 2 × 10⁷ C57SV cells. After 15 d the spleens were removed and a T-cell-enriched fraction was prepared as described earlier. The cells were incubated with 1 × 10⁵ MKSA cells, at a 300:1 lymphocyte:tumour cell ratio, for 45 min at 37 °C in a CO₂ incubator and injected s.c. into normal CBF₁ mice.

‡ CBF₁ mice were inoculated s.c. with 2 × 10⁷ C57SV cells. After 8 d a T-cell-enriched fraction was prepared from the spleens of these mice and used in the *in vitro* ⁵¹Cr release assay. The assay was carried out in the wells of flat-bottom microplates. C57SV target cells were trypsinised and 1 × 10⁴ cells and 5 µCi Na⁵¹CrO₄ in 0.2 ml RPMI 1640 medium containing 5% fetal bovine serum were added to each well. After 18 h at 37 °C in a CO₂ incubator, the target cells were washed and effector cells were added in a 0.2 ml volume in a ratio of 200:1 lymphocyte:target cell. After 6 h incubation at 37 °C in a CO₂ incubator, the plates were centrifuged at 350g for 5 min and 0.1 ml of the supernatant was removed for counting. results are calculated from the mean of triplicate samples and expressed as:

% Specific lysis

$$= \left(\frac{\text{c.p.m. } ^{51}\text{Cr released in the presence of immune cells}}{\text{c.p.m. } ^{51}\text{Cr released in the presence of normal cells} - \text{c.p.m. } ^{51}\text{Cr released in the presence of 1\% SDS}} \right) \times 100$$

The ⁵¹Cr released in the presence of normal cells was always either very close or identical to the release in medium and ranged over 5-15%.

with CFA causes depression of specific anti-tumour cell-mediated immunity by activation of suppressor thymus-derived lymphocytes.

Female CBF₁ (BALB/c × C57BL/6)F₁ mice aged 8-12 weeks (unless otherwise indicated) were used and SV40-transformed cells, C57SV, of C57BL/6 mice. These cells are good targets in the *in vitro* ⁵¹Cr release assay^{7,8} but do not grow *in vivo*. SV40-transformed cells, MKSA, of BALB/c mice grow *in vivo*⁹ but are poor targets *in vitro*. Both cell lines were shown to possess tumour-associated transplantation antigens which can immunise specifically against the growth of MKSA cells^{4,8}.

In the first experiment the mice were inoculated intraperitoneally (i.p.) with 0.5 ml of CFA (0.5 mg ml⁻¹ *Mycobacterium tuberculosis*, Difco) or left untreated, and immediately afterwards they were inoculated subcutaneously (s.c.) with 2 × 10⁷ C57SV cells. (The amount of CFA and the timing of inoculation in relation to C57SV cell immunisation were based on preliminary experiments.) The mice were then divided into three groups. The spleens of the first group of mice were removed 8 d after immunisation^{7,8}, and a T-cell-enriched fraction was prepared using nylon wool columns, as described by Julius *et al.*¹⁰. About 30% of the starting spleen cell population was recovered in the nonadherent fraction; of these, 1-3% (compared to 40-45% in the unfractionated population) were surface immunoglobulin-positive cells, and 0.3% were phagocytic cells (compared to about 5% in the unfractionated population) as judged by latex particle ingestion. The cells were used in the ⁵¹Cr release assay against C57SV target cells. Marked depression of cell-mediated cytotoxic activity was observed in the CFA-treated group as compared to the control group (Table 1). This suppression was demonstrated by using various attacker:target cell ratios and by testing spleen cells at various times after C57SV cell immunisation. The second group of mice was challenged s.c. with 1 × 10⁵ MKSA cells 15 d after immunisation.

Table 2 The effect of CFA-induced suppressor T cells on growth of SV40-induced tumours

Treatment and no. of spleen cells transferred		Challenge with MKSA cells† (dead/total)
Untreated unfractionated	6×10^7	0/10
CFA-treated unfractionated	6×10^7	8/10
CFA-treated unfractionated	3×10^7	1/10
CFA-treated unfractionated	1.5×10^7	1/10
Untreated nylon column	6×10^7	1/10
CFA-treated nylon column	6×10^7	9/10
CFA-treated nylon column	3×10^7	8/10
CFA-treated nylon column	1.5×10^7	1/10
Untreated anti- θ and complement (C)*	6×10^7	2/10
CFA treated anti- θ and C	6×10^7	0/10
CFA treated anti- θ and C	3×10^7	1/10
CFA treated anti- θ and C	1.5×10^7	1/10
CFA treated C alone	6×10^7	8/10

* The preparation of AKR anti-Thy 1.2 C3H antibody and the treatment of lymphoid cells were carried out according to the technique described in detail in ref. 12. This antiserum lysed more than 97% of C3H thymocytes and 35–40% of C3H spleen cells by trypan blue dye exclusion. The T-cell response of spleen cells to phytohaemagglutinin was abolished after treatment, whereas the B-cell response to lipopolysaccharide was left intact.

† CBF₁ mice were inoculated i.v. with various spleen cell preparation as shown and immediately s.c. with 1×10^5 MKSA cells.

The third group was killed 15 d after immunisation and T-enriched spleen cell populations were mixed with 1×10^5 MKSA cells and injected s.c. into normal CBF₁ mice. All the mice were inspected until death from tumour growth.

In both groups, CFA treatment caused suppression of tumour immunity (Table 1); thus, most CFA-treated mice died of progressive tumour growth after challenge whereas no tumours were observed in untreated animals and no animal died. Similarly, in the Winn assay, inhibition of tumour cell neutralisation activity of lymphocytes from CFA-treated mice resulted in tumour growth and death of all animals as opposed to untreated animals, in which tumour cell neutralisation resulted in complete protection against tumour growth. Similar results were observed at various times after immunisation and by using various lymphocyte:tumour cell ratios. Incomplete Freund's adjuvant did not have such an effect. No animal died if inoculated with CFA alone. These experiments suggested that suppression of specific cell-mediated tumour immunity may be caused by either a defect in T-cell function or by activation of suppressor cells. To test these hypotheses further, the following *in vivo* experiment was carried out. Normal CBF₁ mice were inoculated i.p. with 0.5 ml of CFA or left untreated. Seven days later (a time based on preliminary experiments), the animals were killed and their spleens were either left unfractionated, passed through nylon wool columns to remove B cells and phagocytic cells, or treated with specific anti-Thy 1.2 serum and complement to remove T cells. The various spleen cell populations were inoculated intravenously (i.v.) into normal CBF₁ mice which were then injected s.c. with 1×10^5 MKSA cells (the number of tumour cells which in preliminary experiments was found to result in no tumour growth in normal CBF₁ mice as opposed to a higher number of cells). The results of a representative experiment out of two experiments with similar results are summarised in Table 2. Injection of mice with spleen cells from untreated animals, either unfractionated or enriched for T cells or B cells and macrophages, and challenge with MKSA cells did not result in tumour growth or death of these animals. On the other hand, injection of mice with spleen cells from mice pretreated with CFA, either unfractionated or enriched for T cells, resulted in tumour growth and death of the animals.

Treatment of cells with specific anti-Thy 1.2 serum and complement but not with complement alone abolished the suppressive activity. These results suggested that suppressor T cells were generated in CFA-treated animals and suppressed *in vivo* the immune response against MKSA cells.

A similar experiment was carried out using adult thymectomy, as it was shown that adult thymus may actively regulate the function of T cells¹¹. Normal CBF₁ mice 6–8 weeks old were either sham thymectomised, thymectomised or left untreated. Ten days later the mice were inoculated i.p. with 0.5 ml CFA or were left untreated, and all mice were inoculated s.c. with 1×10^5 MKSA cells. The results of a representative experiment out of three experiments with similar results are summarised in Table 3. Normal mice treated with CFA died of tumour growth as compared to nontreated animals. Similar results were obtained with sham thymectomised mice. On the other hand, thymectomy and treatment with CFA did not result in tumour growth, similar to results with thymectomy without CFA treatment. Thus, adult thymectomy reversed the suppressive effect of CFA, and protected mice from the lethal effect of tumour growth.

Table 3 The effect of adult thymectomy and CFA on growth of SV40-induced tumour

Treatment	CFA	Challenge with MKSA cells* (dead/total)
None	—	1/10
None	+	9/10
Sham thymectomy	—	0/10
Sham thymectomy	+	8/10
Thymectomy	—	2/10
Thymectomy	+	1/10

* CBF₁ mice were treated as shown and described in the text and inoculated s.c. with 1×10^5 MKSA cells.

The present study demonstrates the suppression of anti-tumour cellular immunity by treatment with CFA, as assessed by *in vivo* tumour rejection and *in vitro* cell-mediated cytotoxicity, two immunological functions mediated by T cells. CBF₁ mice challenged with syngeneic SV40-transformed cells and CFA failed to develop effector cells, and instead they developed suppressor T cells which inhibited *in vivo* effector T-cell functions. In contrast, adult thymectomy reversed the suppression caused by CFA, suggesting that the intact adult thymus was necessary for the induction of suppressor cells, that is, the thymus may regulate immune responsiveness by the export of suppressor T cells which regulate other T-cell responses. These studies agree with those demonstrating suppression of *in vitro* immune responses to alloantigens by CFA^{13–15}. In contrast to suppressing effector-cell function to antigens, CFA augmented antibody responses to the same antigens^{16,17}. Those studies suggested that increased helper T-cell activity is favoured by adjuvant. Taken together, these and our own studies suggest that CFA has a differential effect on at least two T-cell subpopulations. Regulation of T-cell function is accomplished by the induction of suppressor T cells that selectively interact with pre-killer T cells while sparing helper T cells. A relevant aspect of tumour immunology suggested by the present study is that there may be quite a delicate balance between the beneficial anti-tumour effects of adjuvants and their immunosuppressive effects. Considerable experimentation seems to be necessary to determine the various factors contributing to this complex situation; therefore, caution should be exercised in using adjuvants for immunotherapy of cancer.

I thank Dr Lloyd W. Law for his interest and support and Linda Brunson for help with the preparation of this manuscript. CBF₁ mice were obtained from the NIH breeding colony, C57SV from B. B. Knowles, the Wistar Institute, and AKR anti-Thy 1.2 C3H antibodies from H. Holden, NCI.

Characterisation of a tumour-specific antigen on the surface of feline lymphosarcoma cells

IN domestic cats, regression of tumours originally induced by inoculation of feline sarcoma virus (FeSV) as well as the resistance to feline leukaemia virus (FeLV)-induced lymphosarcoma in the natural environment are correlated with high titres of antibody to the feline oncornavirus-associated cell membrane antigen (FOCMA)¹⁻⁴. FOCMA is present on FeLV-producing and nonproducing feline lymphosarcoma (LSA) cells and FeSV-infected fibrosarcoma cells but is absent from FeLV-infected normal cells. This finding is consistent with the interpretation that FOCMA represents an FeLV or FeSV-induced transformation-specific protein⁵⁻⁷. Other workers have initiated studies of the biochemical nature of FOCMA derived from cytoplasmic extracts of cells of a heterologous species (mink) nonproductively transformed by FeSV⁸⁻¹⁰. However, our primary interest has been to analyse FOCMA expressed on naturally occurring LSA cells from pet cats. We describe here the identification of a hitherto unrecognised protein on the surface of feline LSA cells and cultured transformed feline lymphoblastoid cells which exhibits antigenic determinants in common with FOCMA. The molecular weight of this protein is approximately 70,000. Our data agree with the accumulating evidence that FOCMA is distinct from all FeLV and RD114-coded virion antigens^{4,6-11}.

Cell-surface molecules carrying FOCMA determinants were characterised by methods previously used in studies of murine leukaemia virus-coded cell-surface components of normal and leukaemic murine lymphoid cells: enzymatic radioiodination of viable cells, precipitation with typing serum from detergent lysates, and analysis of proteins in immunoprecipitates by polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulphate (SDS-PAGE)^{12,13}. Correct interpretation of the results obtained was dependent on the availability of monospecific FOCMA typing sera. Therefore, a preliminary comparative analysis of feline sera for antibodies to FOCMA and to FeLV structural protein antigens was made. A panel of selected coded sera were tested for the presence of (1) FOCMA-reactive antibodies by the viable cell membrane immunofluorescence test, (2) FeLV-neutralising antibodies, and

(3) precipitating antibodies to individually purified FeLV-AB virion proteins in radioimmunoassays. We were able to select cat sera (Table 1) which reacted only against FOCMA and not against FeLV structural protein antigens (hereafter referred to as FOCMA typing serum (from a class 6 cat)), sera reacting only against FeLV proteins (class 3 cat), or sera negative for FOCMA or FeLV antibodies (class 5 cat).

Figure 1 shows electropherograms of proteins precipitated from lysates of surface-iodinated primary feline LSA cells by sera from different classes of FeLV-exposed cats. Figure 1a and

Fig. 1 SDS-polyacrylamide gel (PAG) analysis of ¹²⁵I-labelled surface proteins of primary feline lymphosarcoma (LSA) cells precipitated from cell lysates by antibodies in different classes of feline sera (●). Tumour tissue was obtained from animals at autopsy; thymic LSA cells, FeLV-positive in a fluorescent antibody test for FeLV gs antigens¹⁷, were obtained from cat no. 3304. LSA cells negative for FeLV antigen expression were obtained from a lymph node of a second animal (3309) with multicentric LSA. Preparation of cells and radioiodination of cell-surface proteins were accomplished according to protocols published in detail elsewhere¹². Labelled proteins were solubilised by incubating cells in a cell lysis buffer (CLB) (0.05 M NaCl, 0.02 M Tris-HCl, pH 7.4, 0.5% Nonidet P40, 0.5% sodium deoxycholate) containing 10% Trasylol, a general protease inhibitor (FBA Pharmaceuticals). After dialysis for 16 h at 4 °C, insoluble material was removed by centrifugation. For our double-antibody precipitation procedure, 2 µl of test feline sera was added to aliquots of lysate from 5 × 10⁶ cells (final volume 100 µl in CLB, 2-3 × 10⁶ trichloroacetic acid (TCA)-precipitable ¹²⁵I c.p.m.). The suspensions were incubated at 4 °C for 30 min and the total IgG was precipitated by further incubation (4 °C, 2 h) with an excess of rabbit anti-cat IgG. Precipitates were collected by centrifugation at 3,000g and sequentially washed with 1-ml aliquots of cold (1) 0.5 M NaCl, 0.02 M Tris-HCl, pH 7.4, 0.5% NP40, (2) 1.0 M NaCl, 0.02 M Tris-HCl, pH 7.4, 0.5% NP40, and (3) 0.002 M Tris-HCl, pH 7.4, 0.5% NP40. Labelled polypeptides in immunoprecipitates were analysed by PAG electrophoresis in the presence of SDS and 2-mercaptoethanol in 0.5 × 8.5 cm cylindrical gels (7.5% acrylamide) topped with 0.6 × 1.5 cm stacking gels (4.5% acrylamide) according to the method of Laemmli¹⁸. The ratio of acrylamide to bisacrylamide was 30:0.8. After electrophoresis at 3 mA per gel for 3 h, gels were fractionated and ¹²⁵I in the fractions was determined in a Beckman radioimmuno analyser γ counter. a-c show proteins immunoprecipitated from 3304 LSA cell lysate with FOCMA typing serum 3192A (a), FeLV-neutralising serum 2934C (b) and control cat serum 2263A (c). Proteins immunoprecipitated from 3309 LSA cell lysate with feline sera 3192A, 2934C and 2263A are shown in d, e and f, respectively. ³H-glucosamine-labelled AKR murine leukaemia virus was subjected to co-electrophoresis with immunoprecipitates to serve as a marker for viral gp70 (○).

Ultra-low temperature freezers you can depend on.

Forma freezers were made for times like these. Bad times. Because when the power goes off you risk losing some pretty valuable material. That's why the safety is built-in to every cabinet we deliver.

Forma freezers are guaranteed to perform to design operating temperatures as low as -85°C in a warm $+90^{\circ}\text{F}$ (32.2°C) ambient... no other manufacturer will make that promise! This rugged construction means two things: lower operating costs during normal operation and super slow warm-up times that buy time when the lights go out.

Think about it. If you're looking for a dependable ultra-low temperature freezer, look to the company that makes them for the good times and the bad.

Forma... the Freezer People.

Tomorrow's results today

Get gel filtration results faster with Sephacryl S-200 Superfine. It has speed and resolution to spare.

- Cut separation times. Typical flow rates are 30 cm hour or better in standard laboratory columns.
- Cut column packing times. Sephacryl is pre-swollen ready-to-use in packs of 750 ml and packs fast.

Sephacryl S-200 Superfine is the new gel filtration medium for proteins, polysaccharides and other biopolymers. It combines excellent chemical and physical rigidity with an exclusion limit of 250,000 daltons for globular proteins. Sephacryl can be used in detergents, structure-breaking media and organic solvents. It can be autoclaved repeatedly at 120°C.

Don't wait until tomorrow, send for further details today. From your usual supplier of Sephadex, Sepharose and other separation media.

* Classification of Hardy *et al.*⁴. Class 1 cats are those uninfected cats not exposed to FeLV who do not have neutralising or FOCMA antibody. Classes 2, 3 and 4 cats are uninfected cats exposed to FeLV but not persistently infected with the virus; class 2 cats develop antibodies to FOCMA but no FeLV-neutralising antibodies, class 3 cats develop only neutralising antibodies and class 4 cats develop both types of antibodies. Classes 5 and 6 cats are persistently infected with FeLV; class 5 cats develop no FeLV-neutralising or FOCMA-reactive antibodies, and class 6 cats develop only antibodies to FOCMA.

† Immunofluorescent antibody tests of peripheral blood leukocytes¹⁷.

‡ Titres are the reciprocal of serum dilution giving complete neutralisation of the ability of 40 infectious units of FeLV to induce fluorescent foci in cultured feline fibroblasts.

§ Titres are reciprocals of serum dilutions staining at least 50% of 7.5×10^5 target feline transformed lymphoblastoid cells (FL74)⁶.

|| Titres are reciprocals of dilutions of monospecific rabbit immune sera still precipitating 2.5 ng of corresponding radioiodinated FeLV protein.

d shows that antibodies in our FOCMA typing serum precipitated a single protein species from LSA cells, regardless of whether these cells showed concomitant expression of FeLV structural antigens. In contrast, immunoprecipitation of a presumed FeLV gp70 molecule with the FeLV-neutralising serum from a class 3 cat was restricted to the FeLV-positive cells (Fig. 1*b, e*). The latter molecule was not precipitated by serum from the antibody-negative class 5 cat (Fig. 1*c, f*). The data shown are representative of results obtained in a series of experiments with biopsied tumour tissue from thymic, multicentric and alimentary forms of feline LSA. Cells from LSAs of the thymus, lymph nodes, kidneys or blood, including tumours of both T- and B-cell origin, were analysed. The molecular weights of the molecules reactive with the gp70 and FOCMA typing sera were estimated to be about 70,000 daltons by virtue of their co-migration with ³H-glucosamine-labelled AKR virus gp70 subjected to co-electrophoresis. A comparison by co-electrophoresis in slab gels of these molecules and several marker proteins of known molecular weight led to a similar conclusion.

These results suggested that the virus-neutralising serum reacted with cell-surface FeLV gp70 and the FOCMA typing serum with a similarly sized molecule possessing different antigenic characteristics. To clarify the reactivities in these sera for FeLV-producing transformed cells a standard target cell line was needed. For this, we chose the well characterised transformed feline lymphoblastoid line FL74 (ref. 5), the standard line used for detection of FOCMA antibodies in cat sera. These cells had been shown to produce FeLV of A, B and C serotypes and to express FeLV envelope and core protein antigens on their surface^{5,14}. A second transformed feline lymphoblastoid cell line (FOCMA-positive but not expressing FeLV antigens) recently established in our laboratories was also studied as a control (W.D.H. Jr *et al.*, in preparation).

In initial experiments (Fig. 2), using a radioimmuno-precipitation assay as described above, we verified that our FOCMA-reactive and FeLV-neutralising sera recognised cell surface molecules on FL74 cells which were similar to those detected on freshly biopsied tumour tissue. That the FOCMA-specific and FeLV-neutralising cat sera were in fact recognising different 70,000-dalton molecules on these cells was established in absorption experiments. Absorption of FOCMA typing serum with normal cat lymph node cells (cells from six animals were tested, including one replicating FeLV), cultured uninfected or FeLV-producing feline lung fibroblasts (FLF), or cultured heterologous mink lung fibroblasts (CCL64)¹⁵, had a negligible effect on precipitation of FOCMA. However, absorption with LSA cells (three samples of FeLV producers

and four FeLV nonproducers) or heterologous mink lung fibroblasts nonproductively transformed by FeSV (64F3CL7 cells)¹⁵ led to a sharp decrease in precipitating activity, such that electropherograms resembled that obtained with antibody-negative cat serum (for example, Fig. 2*c*). Conversely, absorption of precipitating activity in the FeLV-neutralising serum was achieved with FeLV-infected normal feline lymph node cells, cultured FLF cells and LSAs, but not with FeLV-uninfected cells of those types. In other experiments, complete absorption

Fig. 2 SDS-PAGE analysis of ¹²⁵I-labelled surface proteins of cultured transformed feline lymphoblastoid cells precipitated from cell lysates by antibodies in different classes of feline sera. The transformed feline lymphoblastoid cell lines studied were FL74, producing FeLV of subgroups A, B and C, and 3201B, an FeLV nonproducer line established in this laboratory from a naturally acquired feline lymphosarcoma (W.D.H. Jr *et al.*, in preparation). The cells were maintained as suspension cultures in T-75 plastic flasks (Falcon) using McCoy's medium and 15% fetal bovine serum (FBS). Cell surface proteins were radioiodinated, solubilised, immunoprecipitated and electrophoresed as described in the legend to Fig. 1. *a–c* show polypeptides immunoprecipitated from an FL74 cell lysate with FOCMA typing serum 3192A (*a*), FeLV-neutralising serum 2934C (*b*) and control cat serum 2263A (*c*). Polypeptides immunoprecipitated from 3201B cells with feline sera 3192A, 2934C and 2263A are shown in *d, e* and *f*, respectively. ●, ¹²⁵I c.p.m.; ○, ³H-glucosamine-labelled AKR gp70.

of reactivity in the FeLV-neutralising serum could be achieved with a 70,000 dalton fraction from purified FeLV obtained by gel filtration in the presence of 6 M guanidine hydrochloride (GuHCl)¹⁶, whereas fractions containing p30, p15 and p12 had negligible effects. No absorption of reactivity in the FOCMA-specific serum was achieved with any of these fractions of virus in a parallel experiment. The above results indicate that feline LSA cells express on their surface a 70,000-dalton molecule carrying FOCMA which can be distinguished serologically from cell-surface antigens related to FeLV structural proteins.

FOCMA is also induced by FeSV infections, and evidence suggests that in this instance FOCMA may actually be encoded in the FeSV genome⁹. By gel filtration in 6 M GuHCl of proteins from mink cells nonproductively transformed by FeSV, Stephenson *et al.* detected a protein of 85,000 daltons (p85) expressing FeLV p15 and p12 and FOCMA antigens⁹. Pulse-chase experiments showed that this protein is cleaved to give a 65,000-dalton species containing FOCMA and a 25,000-dalton species containing p15 and p12. In addition, Sherr *et al.* described a phosphorylated polypeptide in pseudotype feline sarcoma virus virions (pp85) that seems to be analogous to the p85 precursor described above¹⁰. Surface molecules of FeSV-transformed nonproducer mink cells (64F3CL7) carrying FOCMA were analysed by radioiodination, immunoprecipitation and SDS-PAGE (Fig. 3). In this case, two protein species were precipitated by FOCMA antiserum, and their mobilities in gels corresponded to the intracellular p85 and p65 species described previously. Neither species was precipitated by the control cat serum (Fig. 3a). Identification of the more slowly migrating species as p85 was supported by our finding that it was precipitated with rabbit antiserum to FeLV p12 (Fig. 3b) or p15 (not shown) but was not reactive with anti-FeLV p30 (Fig. 3b). In a control experiment no protein species from similarly

labelled mink cells nonproductively transformed by Kirsten murine sarcoma virus was precipitated by the anti-FOCMA serum (Fig. 3c). These results suggest that the FOCMA-associated p85 and p65 molecules previously described in FeSV-transformed mink cells are associated with the cell membrane. It is likely that the p65 on 64F3CL7 cells is biochemically similar if not identical to the 70,000-MW species described on feline LSA cells. However, in an analysis of many primary feline LSAs we have not detected a larger species (that is, p85) containing both FOCMA and FeLV gag gene-coded antigens. This suggests that expression of a FOCMA-associated p85 species may be a unique feature of FeSV-transformed cells, and possibly of 64F3CL7 cells in particular.

The biological function of the FOCMA protein is unknown. Purification and further biochemical analysis of this protein should contribute to a better understanding of initiation and maintenance of neoplastic transformation.

Cytogenetic mapping of the trisomic segment of chromosome 15 in murine T-cell leukaemia

A NONRANDOM cytogenetic change in the form of trisomy of chromosome 15 is associated with mouse T-cell leukaemia induced by various agents, such as Gross, Rad and Moloney leukaemia viruses, X rays and a chemical carcinogen, 7,12-dimethylbenz(a)anthracene (DMBA)¹⁻⁴. The uniformity of the chromosomal change and its apparent independence of the inducing agent suggest that it plays an important and perhaps decisive part in the neoplastic transformation of the mouse T lymphocyte. During our studies of the role of chromosome 15 and related factors in lymphoma development, we have investigated whether any particular region of the chromosome needs to be duplicated. Using DMBA to induce T-cell leukaemias in

Fig. 1 Schematic illustration of two alternatives (a and b) for chromosome 15 trisomic T-cell leukaemias in CBAT6T6 mice.

mice carrying chromosome 15 translocations, we have found, and now report that the duplicated chromosome segment is located distal to the T6 breakpoint of chromosome 15.

T-cell leukaemias were induced by feeding DMBA to female and male CBAT6T6 mice (Weizmann Institute) as described elsewhere⁵. Overt leukaemias were transplanted subcutaneously to CBA recipients of the opposite sex. The chromosomes of leukaemic cells of the first passage generation were analysed by G banding. Banded metaphase plates were prepared from subcutaneous tumours, spleens and bone marrow by a slight modification of Wang and Fedoroff's procedure⁶. Magnified photographs were used for karyotype analysis, and trisomic chromosomes were also identified under the microscope in metaphase plates with high banding quality. Chromosome identification followed the nomenclature of the Committee of Genetic Standardization⁷. Because all leukaemic cells originated from donor CBAT6T6 mice, they could be distinguished easily from host cells by the double criteria of the sex chromosome and the T6T6 markers. The CBAT6T6 mouse carries the reciprocal translocation T(14;15)6 (ref. 8). Chromosome 15-trisomic T-cell leukaemias were expected to conform to one of the two patterns illustrated schematically in Fig. 1.

Chromosome counts of six tumours are summarised in Fig. 2. Five out of six leukaemias were aneuploid; tumours with a modal number of 41 chromosomes and tumours with a modal number of 42 and 40 + 1 bi-armed (total 42) chromosomes. Only one tumour (mice 2 and 3) had a modal number of 40 chromosomes. Table 1 shows the results of banding analysis. All five aneuploid leukaemias with a modal number of 41 and 42

1	42	14+8*	T(14;15)6
2	40	20+10*	
5	40+1B	15+15*	T(14;15)6
9	42	10+5*	T(14;15)6
10	42	12+4*	T(14;15)6
11	41	10+8*	T(14;15)6

B, bi-armed. The bi-armed chromosome was formed by centromeric (Robertsonian) fusion between one of chromosomes T(14;15)6 and chromosome 12.

* Karyotyped from magnified photos.

† The second trisomy involved mostly chromosomes 2, 6 and 19.

chromosomes had a trisomy T(14;15)6 (Fig. 3). The second trisomy of tumours with a modal number of 42 chromosomes was distributed randomly, involving mostly chromosomes 2, 6 and 19. The banding pattern of the single tumour with a modal number of 40 chromosomes was indistinguishable from a diploid CBAT6T6 cell.

These results show that the gene(s) that tend to be duplicated during DMBA leukaemogenesis are located distal to the T6 breakpoint of chromosome 15. The consistency of the change further emphasises the specific role of genes associated with

Fig. 3 G-banded karyotype and metaphase plate of a leukaemic cell originating from a female CBAT6T6 mouse and inoculated s.c. into a male CBA mouse. Note the presence of trisomy T(14;15)6 (arrows). The second trisomy involved chromosome 6.

chromosome 15 in T-cell leukaemia. However, the occurrence of a diploid leukaemia in one tumour shows that the change is not exclusive. This agrees with previous findings on AKR and the RadLV leukaemias^{1,2}. In possible analogy with the present work, a specific chromosome aberration affecting one chromosome 14 was found in human B-cell derived neoplasias³, suggesting that certain chromosome segments carry genes that are critical to the neoplastic growth of given target cells.

An inducible gene involved in commitment of lymphocytes to transform

CONCAVALIN A (Con A) stimulates nondividing lymphocytes (in G_0) to transform and enter the division cycle¹. Within 3 h a significant proportion of the cells become committed to transform and do so after the removal of Con A (ref. 2). When the translation of mRNA into protein is inhibited (by low concentrations of anisomycin) lymphocyte transformation is also blocked³. Anisomycin has proved particularly useful in studying lymphocyte transformation because its effect is reversible: in the presence of Con A it holds the cells in G_0 , apparently without adverse effects, and the cells transform following its removal³. Using anisomycin it has been shown that Con A induces the synthesis of factor(s) which commit lymphocytes to transform³. I have examined the stability and nature of the 'transformation signal', again exploiting the reversible effect of anisomycin, and report here that on binding to the surface of nondividing lymphocytes, Con A induces the transcription of a short-lived mRNA. This mRNA encodes a 'transformation factor' which, when translated, commits lymphocytes to enter the division cycle; extracellular Con A is no longer required.

Spleen cells from BALB/c mice (6–10-week-old males) were cultured in RPMI medium (see legend to Table 1). Transformation was measured by the incorporation of tritiated thymidine ($^3\text{H-TdR}$) into cellular DNA over 48–50 h; the stimulation index was calculated as the ratio of c.p.m. in Con A-treated cultures to c.p.m. in control cultures. The mitogenic response to Con A peaked at $1 \mu\text{g ml}^{-1}$ and this concentration was used routinely. Anisomycin (10 ng ml^{-1}) was used to hold Con A-treated cells in G_0 for the first 24 h in culture, after which extracellular Con A was removed using α -methyl-D-

Fig. 1 Plan of experimental procedures described in the text. *a*, The $t_{1/2}$ of the transformation signal was estimated by treating BALB/c spleen cells with Con A ($1 \mu\text{g ml}^{-1}$) plus anisomycin (10 ng ml^{-1}) for 24 h. Con A was removed at 24 h using α -methyl-D-mannoside (50 mM), and anisomycin was continued for a further 2 or 4 h before it also was removed. The cells were then cultured in normal medium and $^3\text{H-TdR}$ was added at 48 h for 2 h to assess DNA synthesis. The cells were collected at 50 h. *b*, The possibility that the transformation signal might be mRNA was examined by culturing BALB/c spleen cells with Con A ($1 \mu\text{g ml}^{-1}$) plus anisomycin (10 ng ml^{-1}) for 24 h. At 22 h α -amanitin ($10 \mu\text{g ml}^{-1}$) was added to inhibit mRNA transcription for 2 h and mRNA translation was then inhibited by anisomycin for a further 2 h after the removal of Con A plus α -amanitin. The cells were subsequently cultured and labelled as above. α = α -amanitin.

mannoside³. Additional experimental procedures are summarised in Fig. 1.

The stability of the transformation signal was estimated by continuing anisomycin for various periods after the removal of Con A. The cells recovered and transformed when anisomycin was continued for 2 h after Con A removal but when it was continued for 4 h after Con A removal cell transformation fell by 60% (Table 1). This indicates a half life ($t_{1/2}$) of approximately 3–4 h for the transformation signal (in the presence of anisomycin). This relatively short $t_{1/2}$ suggests that it must be continually expressed in Con A-treated cells held in G_0 for 24 h (by anisomycin) because the cells transform following the simultaneous removal of mitogen plus inhibitor³. Continuous production of the transformation factor presumably depends on the continued presence of Con A, as the ability of the cells to transform fell rapidly 2 h after the removal of Con A (Table 1).

α -Amanitin, a selective inhibitor of mRNA transcription^{4,5}, was used to examine the possibility that the transformation signal might be a species of mRNA transcribed in response to Con A. If the signal is Con A-dependent mRNA, with a $t_{1/2}$ of 3–4 h, it follows that cell transformation should decline markedly when mRNA transcription (in the presence of Con A) and translation (in the absence of Con A) are inhibited sequentially for 2 h each. Again, spleen cells were cultured with Con A plus anisomycin for 24 h. α -Amanitin ($10 \mu\text{g ml}^{-1}$) was added to the cultures at 22 h and removed at 24 h, together with the Con A (Fig. 1*b*). Anisomycin was continued for a further 2 h before it also was removed. Experimental controls showed that continued exposure to α -amanitin blocked transformation, whereas cells recovered and transformed when exposed to either α -amanitin at 22–24 h or continued anisomycin for 2 h after Con A removal (Table 2). However, transformation fell by 50% in those cells treated with α -amanitin 2 h before and anisomycin 2 h after the removal of Con A. In other words, the sequential inhibition of mRNA transcription and translation for a total of 4 h resulted in a 50% drop in cell transformation, consistent with the transformation signal being mRNA.

Interpretation of these results clearly depends on the actions of the two antibiotics α -amanitin and anisomycin. In cell-free systems, each has been shown to be highly selective: anisomycin blocks peptidyl transferase activity on 80S ribosomes⁶ and α -amanitin inhibits RNA polymerase II^{4,5} (mRNA synthesis). At very high concentrations ($\geq 200 \mu\text{g ml}^{-1}$) α -amanitin also

Table 1 Recovery and transformation after prolonged anisomycin inhibition for 1, 2 and 4 h after removal of Con A (see Fig. 1a)

Treatment	³ H-TdR incorporation (c.p.m.)	Stimulation index
Untreated control	2,645	—
Con A throughout	48,273	18
I Con A + anisomycin throughout	3,267	1.2
Con A removed at 24 h	44,842	17

Con A + anisomycin, removed at 26 h	42,375	16
Con A + anisomycin, removed at 28 h	17,290	6.5

BALB/c spleen cells exposed to Con A ($1 \mu\text{g ml}^{-1}$) and anisomycin (1 ng ml^{-1}): the $t_{1/2}$ of the transformation factor was determined by continuing anisomycin inhibition for various periods after removal of Con A at 24 h. Washed spleen cells from a single mouse were diluted to $5 \times 10^6 \text{ ml}^{-1}$ with RPMI plus 100 IU ml^{-1} penicillin and 100 $\mu\text{g ml}^{-1}$ streptomycin. Aliquots (100 μl) were dispensed into flat-bottomed wells of a microtitre tray and cultured in a humidified atmosphere of 10% CO_2 in air at 37°C . After removal of Con A (group II) the medium was replaced with Con A-free medium plus α -methyl-D-mannoside (50 mM) to displace any cell-bound Con A (ref. 3). At 25 h the medium was replaced with normal medium. Anisomycin (10 ng ml^{-1}) was added to the replacement media for 1, 2 or 4 h after the removal of Con A; thereafter, it was replaced with normal medium. Transformation was assessed by measuring DNA synthesis using standard techniques after labelling each culture with 2 μCi [$6\text{-}^3\text{H}$]thymidine (specific activity 5 Ci mmol^{-1}) for 2 h at 48–50 h. Each value represents the mean of four cultures.

inhibits RNA polymerase III⁷ (tRNA and 5S RNA synthesis). Intact cells are reputed by some to be impermeable to α -amanitin and this seems to be true for rat hepatoma cells⁸. However, this is not a generalised phenomenon and normal rat liver cells *in vivo*⁹, adrenal cortical cells⁹ and lymphocytes *in vitro* (this work) are all sensitive to α -amanitin at concentrations known to block mRNA synthesis selectively. α -Amanitin may also indirectly affect rRNA synthesis which seems to depend on

Table 2 Recovery and transformation after the sequential inhibition of mRNA transcription (by α -amanitin) and translation (by anisomycin) for 2 h each (see Fig. 1b)

BALB/c spleen cells cultured and labelled as described in the legend to Table 1. Group I, Con A present throughout, group II, Con A removed at 24 h. Anisomycin (10 ng ml^{-1}) and α -amanitin ($10 \mu\text{g ml}^{-1}$) were added to the culture medium as indicated. Each value represents the mean of four cultures.

mRNA with a $t_{1/2}$ of about 20 min (see ref. 10, in which actinomycin D, rather than α -amanitin, was used). If rRNA synthesis in lymphocytes is similarly affected by α -amanitin the effect must be reversible, as inhibition for 2 h is reversible (Table 2). It follows that the present results with α -amanitin cannot be attributed to an indirect effect on rRNA synthesis.

Using α -amanitin and anisomycin as inhibitors of mRNA transcription and translation respectively it has been shown that (1) the transformation factor in lymphocytes seems to be coded for by mRNA; (2) the mRNA has a $t_{1/2}$ of 3–4 h; (3) extracellular Con A is necessary for its continuous production when cell transformation is blocked by anisomycin. The effect of anisomycin is reversible and when mRNA translation is allowed to proceed normally (within 2 h of Con A removal), the cells transform independently of extracellular Con A. On the basis of these observations it is postulated that Con A induces the transcription of a new species of mRNA(s) in lymphocytes. When this mRNA is translated the newly synthesised protein takes over and commits the cells to enter the division cycle; extracellular Con A is no longer required.

Release of vasoactive intestinal polypeptide in mast cells by histamine liberators

VASOACTIVE INTESTINAL POLYPEPTIDE (VIP), originally isolated from porcine duodenum¹, is a potent relaxant of vascular and nonvascular smooth muscle², and a stimulant of adenylate cyclase activity^{3,4}. The peptide has been localised in endocrine cells in the gastrointestinal tract and pancreatic islets^{5,6}, as well as in nervous structures in these and other organs^{7–9}, the peripheral autonomic nervous system and selected areas of the brain^{8–11}. We report here immunological evidence that VIP, or a closely related peptide, occurs in mast cells, from which it can be released by compound 48/80 or by the Ca^{2+} ionophore A23187.

Rat peritoneal mast cells were collected from the peritoneal cavities of rats. Under ether anaesthesia, the rats were injected intraperitoneally with 12 ml of Sorensen phosphate buffer, pH 7.0. The rats were killed with ether 5–10 min later, their abdomens were opened and the peritoneal fluid removed and centrifuged at 400g for 8 min. The cell pellet, resuspended in 2–3 ml of buffer per rat, contained approximately 10^6 mast cells (10% of the total cell population). Aliquots of washed cell suspensions were incubated for 15 min at 37°C with 0.1 μg per ml of compound 48/80 (Burroughs-Wellcome) or 1 μg per ml of Ca^{2+} ionophore A23187 (Lilly). After incubation the media were separated from the cells by centrifugation at 400g for 8 min. The supernatants were decanted and then assayed for VIP immunoreactivity by a specific radioimmunoassay¹² sensitive to 10 pg per ml, and for histamine by the fluorometric method of Shore¹³. The amounts of the peptide and amine released were expressed as per cent of their respective total

Table 1 VIP and histamine in rat peritoneal mast cells

content, measured after disrupting the cells by boiling in water for 3 min.

The mean VIP content in suspensions of rat peritoneal mast cells (3.6 ± 0.8 ng per ml or 1.4 ng per 10⁶ mast cells) was a fraction of their histamine content (689.3 ± 3 ng per ml); 1 ml contained approximately 4 × 10⁵ mast cells. Incubation of the cells with compound 48/80 or with A23187 provoked release of the peptide in proportions similar to those of the associated histamine release (Table 1).

For immunohistochemical studies, VIP antibodies were raised in rabbits against porcine VIP (GIH Laboratory, Stockholm), and included the same antibody (89N) used for radioimmunoassay, and two others (TR₁ and TR₂). Samples of lung and small intestine were obtained from adult and newborn Wistar rats and from mice, and were processed for immunohistochemistry according to the method of Pearse and Polak¹⁴. The samples were quenched in melting Arcton 22, freeze-dried, vapour-fixed in recrystallised benzoquinone at 60 °C for 3 h and embedded in paraffin; sections were cut at 5–7 µm. Pellets of rat peritoneal mast cells were processed for immunohistochemistry in the same way. The indirect immunofluorescence technique (24–48 h incubation at 4 °C) was carried out using the three VIP antibodies (dilutions 1:5 to 1:100), and antibodies against porcine secretin, synthetic human G-17 gastrin and porcine glucagon. As a second layer, fluorescein-labelled goat anti-rabbit IgG was used. The following control procedures were carried out: (1) incubation with VIP antisera (1:5) to which pure VIP (60 µmol per ml) had been added; (2) the first layer was replaced by non-immunised rabbit serum or phosphate buffer; (3) incubation with the second layer only. Following examination under the fluorescence microscope the sections were stained with toluidine blue (pH 5) to identify and confirm the presence of mast cells.

Sections of rat and mouse lungs incubated with VIP antisera (up to 1:100 dilutions) showed strong positive fluorescence in mast cells in perivascular, peribronchial and interstitial locations (Fig. 1). Examination at higher magnification revealed that VIP was localised within mast-cell granules (Fig. 1 inset). Mast cells

Fig. 1 Many strongly fluorescent, VIP-immunoreactive mast cells in rat lung. Mast cells are scattered in the connective tissue, but some are concentrated along the wall of a blood vessel (BV). (Indirect immunofluorescence method, VIP antibody TR₂, 1:50, ×400.) Inset, higher magnification (×900) of mast cells showing VIP immunoreactivity confined to cytoplasmic granules (arrow).

in sections of small intestine and in cell preparations from peritoneal lavage also showed strong VIP immunoreactivity. No fluorescence was observed with VIP-treated VIP antisera, or with the antisera against the other peptides. Mast cells were cross-identified in sections stained with toluidine blue; the cells contained typical metachromatic granules and their size, appearance and distribution were identical to those of VIP-immunoreactive cells.

The demonstration of immunoreactive VIP in mast cells from different locations from two mammalian species, and the release of the peptide by histamine releasers suggest interesting functional implications. The mast cell is the principal target cell in immediate hypersensitivity, playing a key part in anaphylaxis, extrinsic (allergic) asthma, hay fever and other IgE-dependent immunological responses¹⁵. The release of VIP by the ionophore A23187 is of special interest as this agent releases histamine by a mechanism similar to that of anaphylaxis¹⁶. As VIP stimulates the production of cyclic AMP in the lung and other tissues^{3,4}, and as agents which promote cyclic AMP accumulation in the lung also inhibit mediator release¹⁷, VIP could have an important modulating influence on the release of histamine and other mediators from mast cells.

Further, VIP may, when discharged from pulmonary mast cells, exert its relaxant actions on bronchial and vascular smooth muscle², providing another level of modulation of airway and vascular responses by the peptide.

VIP immunoreactivity has been reported in peptide extracts of normal porcine lungs¹⁸. The evidence presented here of VIP immunofluorescence in pulmonary mast cells provides an anatomical basis for that finding. Finally, mast cells are widely distributed in connective tissues of various organs of the body and are generally concentrated along the blood vessels. VIP in mast cells is therefore in a position to influence local or regional blood flow, in normal or pathological conditions.

We thank Dr J. Gauldie, McMaster University, for help with the production of VIP antibodies TR₁ and TR₂. This work was supported in part by a grant from the Ontario Thoracic Society and by a Lung Center Award from the National Heart, Lung and Blood Institute, USPHS.

Are dopamine receptors accessible to intracellularly applied agonist?

THERE is much evidence that receptors to neurotransmitters are generally on the outer surface of cell membranes¹⁻³. The experiments reported here raise the possibility that acinar cells of cockroach salivary glands may be activated intracellularly as well as by extracellularly applied agonists.

Studies were performed using the isolated innervated salivary gland of *Nauphoeta cinerea* (Olivier) bathed in flowing solution (2 ml min⁻¹) containing (mM) NaCl, 160; KCl, 1; CaCl₂, 5; Tris-HCl pH 7.6 buffer, 5 and mounted as previously described⁴. Cells were impaled with microelectrodes containing agonists in concentrations of up to 1.0 M dissolved in either potassium acetate or KCl. The electrodes were used not only for intracellular recording but also for ejecting the agonist by means of current pulses. The reservoir ducts were drawn into a small suction electrode to allow stimulation of the salivary nerve. Figure 1a shows two successive responses of an acinar cell, N to a single nerve stimulus and D to the application of a current pulse to the intracellular electrode equivalent to a charge of 40 nC. The responses can be seen to be very similar. In Fig. 1b the response to a burst of nerve stimuli, N, is followed by three responses to increasing ionophoretic charges and it can be seen that there is a graded relationship between amplitude of response and charge.

Intracellular applications of dopamine were made to about 100 cells and responses were obtained from about two-thirds of these. In a few experiments responses were also obtained from intracellular applications of adrenaline, noradrenaline and 5-hydroxytryptamine which, like dopamine, have also been shown to be effective when applied extracellularly⁵.

Two possible explanations for these responses are (1) receptors are activated intracellularly by the ionophoretically applied agonists or (2) the receptors on the outer membrane surface are activated by agonist which has leaked through the membrane. Attempts to distinguish between (1) and (2) have so far been inconclusive. In one experiment we compared the sensitivity of a series of cells to extra- and intracellular application from the same ionophoretic pipette. The cell was first impaled with a separate recording electrode, the ionophoretic pipette was brought as close as possible to the outer surface of the acinus and a response to a pulse of dopamine was elicited. An attempt was

Fig. 1 a, Lower trace, voltage; upper trace, current passed through recording electrode. N, intracellularly recorded response to a stimulus applied to the salivary nerve; D, response to a dopamine pulse ejected by a 100 nA current for 0.4 s. Downward deflection corresponds to hyperpolarisation. The electrode contained 0.7 M dopamine and 1 M potassium acetate. b, Intracellular response, N, to a burst of three nerve stimuli followed by responses to three pulses of dopamine ejected from the intracellular electrode by currents of 100 nA for durations of 0.2, 0.4 and 0.6 s respectively. The electrode contained 0.3 M dopamine and 1 M potassium acetate.

Fig. 2 Effect of phentolamine on intracellularly recorded responses from the same cell. a, Int, pulses of dopamine ejected from the intracellular electrode (100 nA for 0.4 s); Ext, pulses of dopamine ejected from an extracellular pipette (200 nA for 0.08 s). Both electrode and pipette contained 0.5 M dopamine and 3 M potassium acetate. Top records, control; middle records, during recovery from a short exposure to 150 μ M phentolamine; bottom records, in 25 μ M phentolamine. b, part of time course of experiment from which records in a were taken. $\circ$, Intracellularly applied dopamine; $\square$, extracellularly applied dopamine.

then made to insert the ionophoretic pipette. The initial recording electrode was usually dislodged in the process but this did not matter because if the cell was successfully impaled with the ionophoretic pipette it could also be used for recording. Little difference was found between the maximum sensitivities with the two different methods of application. For an electrode containing 50 mM dopamine in 3 M potassium acetate the largest value for the ratio of response to ionophoretic charge was 3 mV nC⁻¹ for intracellular and 2.3 mV nC⁻¹ for extracellular application. (If it is assumed that half the current is carried by cations and that the transport number of the dopamine ion is the same as that of K⁺, 1 nC would correspond to the ejection of about 10⁻¹⁶ mol; this would give rise to an internal concentration of about 10⁻⁷ M if the dopamine was uniformly distributed throughout an acinus of the usual diameter of about 100 μ m.) This result might be thought to argue against the leakage hypothesis, (2), but the result of a second type of experiment was found to be consistent with it. Cells were impaled with one ionophoretic pipette for intracellular recording and dopamine application and a second similar pipette was placed close to the acinar surface for extracellular dopamine application. After matching responses were obtained, phentolamine⁵, which is known to antagonise extracellularly applied dopamine⁵, was added to the flowing bathing solution. Responses to both intracellular and extracellular dopamine were reduced to the same extent (Fig. 2); thus the leakage hypothesis cannot be rejected. However, as phentolamine may be able to leak into the acinar cells, the possibility that the receptors might be accessible from both sides of the membrane cannot be excluded.

Ionophoretic model for Na-Ca counter transport

IN most mammalian cells the cytosolic concentration of free ionised Ca^{2+} is thought to approximate 10^{-6} – 10^{-7} M, whereas the extracellular Ca^{2+} concentration is close to 10^{-3} M (ref. 1). The efflux of Ca^{2+} across the cell membrane, which takes place against an electrochemical gradient, is apparently mediated either by a Ca^{2+} -stimulated ATPase² or by a Na-Ca counter transport process. In the latter process, the entry of Na^+ into the cell, which is a passive event driven by the electrochemical gradient of Na^+ across the plasma membrane, is thought to be coupled with the uphill outwards transport of Ca^{2+} (ref. 3). Although a possible modulatory effect of ATP on such a process has been suggested, it is generally assumed that the Na-Ca counter transport mechanism does not consume ATP (discussed in ref. 4). Because several passive ionic movements (such as the influx of Na^+ or Ca^{2+} into the cell) could be mediated by native ionophoretic molecules, we have explored whether it was possible, using an artificial system for the study of ionophoresis, to reproduce the major characteristics of the Na-Ca counter transport process. We report here our success.

A CCl_4 organic phase (3.2 ml) containing Br-X537A (1.4 mM, Roche) was placed in the bottom of a Pressman cell⁵. Ionophore Br-X537A was used because it transports both monovalent and divalent cations⁶. The composition of the supernatant aqueous phases (1.6 ml) which was placed in each chamber of the Pressman cell is given in the legend of Fig. 1.

At the end of the experiments—after 24 h—the immiscible organic phase contained only trace amounts of ^{22}Na , representing no more than $0.22 \pm 0.05\%$ of the total radioactivity in the system. The ^{45}Ca content of the final immiscible phase was greater. Relative to the total amount of radioactivity present in the system and with 4 mM Ca^{2+} in each chamber, it averaged $4.5 \pm 0.7\%$ ($n=13$) and $11.8 \pm 1.0\%$ ($n=8$) in the presence of Na^+ (121 mM in both chambers) and the absence of Na^+ , respectively. These values correspond to apparent calcium concentrations, in the immiscible phase of 0.18 ± 0.03 and 0.47 ± 0.04 mM (as distinct from 2.4 ± 0.9 μM in the absence of X537A).

In the absence of ionophore, no significant amount of ^{22}Na ever seemed to be translocated. Relative to the total amount of ^{45}Ca present in the system, the transfer rate for ^{45}Ca averaged no more than $0.21 \pm 0.03\%$ per h.

In the presence of Br-X537A but in the absence of ionic gradient, that is when both aqueous phases had the same ionic concentration at time zero, ^{45}Ca (which was added to only one of the chambers) moved towards the other chamber, and eventually the radioactivity was equally distributed among both chambers (Fig. 1, left). At the same Ca^{2+} concentration (4 mM), the initial rate at which the radioactivity moved from one chamber to the other was greater in the absence than in the presence of Na^+ (120 mM). The latter observation is consistent with the fact that Na^+ decreases the ability of the ionophore to translocate ^{45}Ca into an organic immiscible phase (our unpublished observation). When 4 mM Ca^{2+} and 120 mM Na^+ were present in both chambers, ^{22}Na was transferred relatively slowly (approximately 1.0% of the total radioactivity transferred per h) so that, even after 24 h, the partition equilibrium for ^{22}Na was not reached.

The pattern for ^{45}Ca translocation was different when an ionic gradient was imposed on the system at time zero. When 4 mM Ca^{2+} was present in both chambers, but Na^+ was distributed asymmetrically (120 mM out (O) and 6 mM in (I)), most of the ^{45}Ca initially added to the I compartment was transferred to the O compartment. After 24 h, more than 80% of the total radioactivity was recovered in the O chamber. This occurred independently of any electrical gradient, also being observed

when the two chambers were connected by an agar-agar bridge (4%, w/v, in Hartmann's solution Na^+ 158 mM, K^+ 5 mM, Ca^{2+} 2 mM, Cl^- 139 mM, $\text{CH}_3-\text{CHOH}-\text{CO}_2^-$ 28 mM). When, in addition to the Na^+ gradient (120 mM O and 6 mM I), a Ca^{2+} gradient (0.2 mM I and 4 mM O) was also introduced, up to 90% of the ^{45}Ca initially present in the I compartment was transferred to the O compartment. A dramatic uphill translocation of $^{45}\text{Ca}^{2+}$ (I $\rightarrow$ O) also occurred when only a trace of $^{45}\text{Ca}^{2+}$ (1.0 μM) and no $^{40}\text{Ca}^{2+}$ was added to the I chamber (data not shown). These observations indicate that ^{45}Ca can move against the Ca^{2+} gradient. The initial rate of ^{45}Ca transfer was much greater when the Ca^{2+} gradient was superimposed on to

Fig. 1 Transfer of ^{45}Ca (upper graphs) and ^{22}Na (lower graphs) in a Pressman cell, across an immiscible organic phase containing Br-X537A. The aqueous phases consisted of a Hepes solution (25 mM) buffered to pH 7.0 with either NaOH or $\text{Ca}(\text{OH})_2$ and containing, as required, CaCl_2 , NaCl and trace amounts of $^{45}\text{CaCl}_2$ (0.5–1.0 $\mu\text{Ci ml}^{-1}$) or $^{22}\text{NaCl}$ (0.25 $\mu\text{Ci ml}^{-1}$). The organic phase was stirred continuously (about 120 r.p.m.) with a magnetic bar, the experiments being carried out at room temperature (about 22 °C). At the onset of the experiments and at timed intervals thereafter, a sample of the aqueous phase (0.05 ml) was removed from each chamber and examined for its radioactive content by liquid scintillation counting. The observed radioactivity was corrected for the change in volume due to the sampling procedure. Evaporation was minimised by the use of a glass cover and was corrected for by expressing individual data as a percentage of the total radioactivity recovered at each sampling time in both the I and O chambers. In the left panels, both aqueous phases contained Ca^{2+} (4 mM) in the presence (★) or absence (●) of Na^+ (120 mM). The control data for ^{45}Ca translocation obtained in the absence of Br-X537A are also shown (○). In the right-hand graphs, a Na^+ gradient (120 mM O, and 6 mM I) was always used, either the same Ca^{2+} concentration (4 mM) being initially present in both aqueous phases (○) or a Ca^{2+} gradient (0–0.2 mM I, and 4 mM O) being superimposed on the Na^+ gradient (●). The data for ^{45}Ca always refer to the radioactivity found in the O compartment, whether ^{45}Ca was initially located in the I (ascending curves) or O (upper flat curve) chamber. The data for ^{22}Na always refer to the radioactivity found in the I compartment, the tracer being in all cases initially located in the O chamber. In the inset (upper right graph), the data for ^{45}Ca transfer (●) are shown in a semi-logarithmic plot, the difference between equilibrium and observed values for ^{45}Ca being ranged on a logarithmic scale. Mean values ($\pm$ s.e.m.) refer to 6–12 individual experiments.

the Na^+ gradient than when only the Na^+ gradient was initially present (Fig. 1, right). This difference is attributable to the much lower initial Ca^{2+} concentration (0.2 mM compared with 4.0 mM) in the I compartment, so that much more radioactivity moved from I to O even if the same total Ca^{2+} was translocated in the same direction. Using a comparable experimental design (that is Na^+ 120 mM O and 6 mM I; Ca^{2+} nil I and 4 mM O) but with ^{45}Ca initially located in the O chamber, about 95% of radioactivity remained in the O chamber, even after 24 h of incubation. In all these experiments, ^{22}Na (which was initially located in the O chamber) moved in the I chamber at a rate comparable with that seen in the absence of Na^+ gradient (Fig. 1, lower graphs). Less than 15% of the total ^{22}Na was transferred from the O to the I chamber after 24 h of incubation.

The true concentration of Na^+ and Ca^{2+} in the two chambers was also measured. In the absence of ionophore, Na^+ and Ca^{2+} concentrations remained close to their respective initial values, whatever the experimental conditions (data not shown). In the presence of the ionophore Br-X537A and with a Na^+ gradient (Na^+ 120 mM O, and 6 mM I; Ca^{2+} 4 mM on both sides), the Ca^{2+} concentration progressively decreased in the I compartment and concomitantly increased in the O compartment at a mean rate of 0.48 ± 0.02 mM per h, so that 96% of the total amount of Ca^{2+} was present in the O chamber at the 8th h. In the presence of both Na^+ and Ca^{2+} gradient (Na^+ 120 mM O and 6 mM I; Ca^{2+} 4 mM O and nil I), no significant translocation of Ca^{2+} was observed, the concentration of Ca^{2+} plateauing at 4.06 ± 0.04 mM in the O chamber and no detectable amount of Ca^{2+} (less than 0.1 mM) appearing in the I chamber, even after 24 h. In both types of experiment, the Na^+ concentration slightly decreased in the O chamber and concomitantly increased in the I chamber at a rate not exceeding 0.8 ± 0.3 mM per h. Even at the 24th h, the concentration of Na^+ remained six to seven times higher in the O than in the I chamber.

The experimental condition which mimics more closely the situation encountered in most mammalian cells corresponds to the following distribution: in the O chamber (that is the extracellular fluid) Na^+ 120 mM and Ca^{2+} 4 mM; in the I chamber (that is the intracellular compartment) Na^+ 6 mM and $\text{Ca}^{2+} \leq 0.2$ mM. In such conditions the initial rate of transfer of radioactivity averaged 0.9% per h for $^{22}\text{Na}(\text{O} \rightarrow \text{I})$ and at least 88.0% per h for $^{45}\text{Ca}(\text{I} \rightarrow \text{O})$; see inset Fig. 1). These values correspond to cationic fluxes of 1.1 mM Na^+ per h and 0.2 mM Ca^{2+} per h. In living cells, three to four sodium ions are thought to enter the cell for each Ca^{2+} ion extruded by the Na-Ca counter transport process⁷.

In conclusion, Br-X537A can represent a model for the Na-Ca counter transport process. Our results show that a Na^+ gradient can be sufficient to maintain a Ca^{2+} gradient and to insure the transport of Ca^{2+} against such a gradient by ionophoresis.

Potassium channels in the apical membrane of the toad gallbladder

It has been demonstrated that the apical and the basolateral cell membrane of the gallbladder have a high K^+ permeability^{1,2} and that the electrochemical potential for potassium in the cytosol is about 50 mV more positive than that in the bathing solutions³. Because of the existence of an $(\text{Na}^+, \text{K}^+)\text{ATPase}$ ⁴ which is located on the basal lateral surface of the epithelial cells⁵, it is possible that K^+ is actively transported in the cells at the serosal side and partially leaves the cellular compartment through the apical membrane under the influence of its electrochemical gradient. In the present study we have investigated this hypothesis by analysis of the current fluctuations recorded in voltage-clamp conditions. This method has been shown to be very useful for the investigation of the kinetic properties of ion transport in such different biological tissues as nerve, postsynaptic membranes^{6,7} and epithelia⁸. We have found K^+ -selective channels which open and close randomly in the apical membrane of the toad gallbladder. However, this study did not reveal the presence of fluctuating ionic channels in the serosal membrane.

The gallbladder epithelium of the Mexican toad *Bufo marinus* was mounted in a modified Ussing chamber with a free surface of 0.16 cm^2 . With Na Ringer's solutions (115 mM NaCl, 1 mM CaCl_2 , 1 mM MgCl_2 , 1.08 mM K_2HPO_4 and 0.36 mM KH_2PO_4) on both sides, the transepithelial resistance was $212 \pm 15 \Omega \text{ cm}^2$ ($n = 79$) and the transepithelial potential was $0.44 \pm 0.16 \text{ mV}$ ($n = 34$), serosa positive. Strong amplification of this potential reveals that it is not constant but fluctuates around its macroscopic mean value. These voltage fluctuations were clamped to zero with a low-noise voltage-clamp circuit using a FET input amplifier⁹. The resultant current noise signal was sampled at a frequency of 500 Hz. The power spectrum of a time series of 2,048 data points was calculated on a PDP11/34 computer. The final spectra represent an average of 40 records.

With Na Ringer's on both sides, we observed a spontaneous lorentzian component in the power spectrum in 30 of 95 bladders (curve *a* in Fig. 1A). The plateau value (S_0) and the corner frequency (f_c) could be quite accurately determined in 16 bladders: $S_0 = 3.7 \pm 0.8 \times 10^{-19} \text{ A}^2 \text{ s cm}^{-2}$ and $f_c = 4.0 \pm 0.2 \text{ Hz}$. In many cases, as in curve *a* of Fig. 1B, there was also a low-frequency noise component. In most of the experiments the lorentzian component was either masked by low-frequency noise or its intensity was too small to be detectable. The lorentzian noise component could be caused by one of the following mechanisms: (1) conductance fluctuations in one of the cell membranes or in the paracellular shunt produced by 'open and close' kinetics of ion-selective channels; (2) fluctuations in the active ion-transport flux in the case of an electrogenic transport mechanism. The relaxation time, τ , of the process we measured can be calculated from f_c ; thus, $\tau = 1/(2\pi f_c)$, being in this series of experiments $41 \pm 2 \text{ ms}$. The addition of a metabolic inhibitor (3 mM KCN + 3 mM sodium iodoacetate) to the serosal solution resulted in a complete disappearance of the lorentzian component within 20 min (Fig. 1A). The application of 1 mM ouabain to the serosal solution caused a slow decrease of S_0 with a concomitant increase of f_c (Fig. 1B). From these experiments it cannot be concluded that the underlying transport mechanism is an active one because the inhibition of active transport reduces the electrochemical gradients across the mucosal and the serosal membrane². Consequently, it is possible that the metabolic inhibitors and ouabain cause an indirect decrease of S_0 by reducing the driving force for passive ionic movements. The increase of f_c after ouabain cannot be explained with the available data.

In most of the remaining bladders we investigated, large low-frequency components were recorded and a lorentzian component could not be detected with Na Ringer's on both

Fig. 1 Power spectra of the current fluctuations through the toad gallbladder epithelium in control conditions and after the addition of various agents. **A**, Curve *a*, spontaneous lorentzian noise spectrum recorded with Na Ringer's on both sides. The plateau value is $S_0 = 4.3 \times 10^{-19} \text{ A}^2 \text{ s cm}^{-2}$ and the corner frequency $f_c = 5.3 \text{ Hz}$. Curve *b*, fluctuations are depressed to levels comparable to the amplifier noise after the addition of 3 mM KCN + 3 mM sodium iodoacetate. Because of the capacitive reactance component in the membrane impedance, the amplifier noise increases in the high frequency range and may become larger than the excess noise of the preparation¹⁵. This explains the increase of the spectral density observed at higher frequencies. **B**, Influence of ouabain. Curve *a*, spectrum recorded in control conditions: $S_0 = 2.7 \times 10^{-19} \text{ A}^2 \text{ s cm}^{-2}$ and $f_c = 5.7 \text{ Hz}$. Curve *b*, 15 min after the addition of 1 mM ouabain to the serosal solution: $S_0 = 1.2 \times 10^{-20} \text{ A}^2 \text{ s cm}^{-2}$ and $f_c = 17.1 \text{ Hz}$. Curve *c* was recorded 35 min after the addition of ouabain. **C**, Influence of TEA. Curve *a*, lorentzian recorded with Na Ringer's on the serosal side and with Ringer's in which all Na^+ was replaced by K^+ on the mucosal side: $S_0 = 3.1 \times 10^{-18} \text{ A}^2 \text{ s cm}^{-2}$ and $f_c = 4.7 \text{ Hz}$. Curve *b*, the addition of 5 mM TEA to the mucosal solution abolished the current fluctuations.

sides. The low-frequency component could be depressed by replacing 36 mM of the serosal Na^+ by K^+ . It cannot be excluded that these fluctuations, which we shall not discuss further, are due to smooth muscle activity, and consequently can be depressed by a K^+ -induced depolarisation. A lorentzian could be shown in 71% of these preparations after replacing all Na^+ by K^+ at either the mucosal or the serosal side. This indicates that the underlying mechanism depends on the presence of potassium in the bathing solutions. We therefore investigated the dependence of S_0 and f_c on the mucosal ($[\text{K}]_m$) and the serosal ($[\text{K}]_s$) K^+ concentration. These experiments were done with bladders which showed a spontaneous lorentzian component in the power spectrum. During all Na^+/K^+ replacements f_c did not change significantly. The substitution of 36 mM of the mucosal Na^+ by K^+ led to a complete disappearance of the lorentzian component (Fig. 2). The increase of $[\text{K}]_m$ reduces the electrochemical gradient across the mucosal membrane¹¹, so that possibly the K^+ efflux to the mucosal side decreases. A further increase of $[\text{K}]_m$ enhanced the fluctuations, and the lorentzian component reappeared. At $[\text{K}]_m = 115 \text{ mM}$, S_0 was even larger than in control conditions. In these circumstances a K^+ influx through the mucosal membrane can be expected. An increase of $[\text{K}]_s$ led to an increase of S_0 over the entire range of K^+ concentrations. Even after poisoning the epithelium with a metabolic inhibitor, the lorentzian component could be observed in the spectra when a large K^+ gradient was applied.

From these data it can be concluded that the relaxation process underlying the lorentzian component is related to K^+ movements through the mucosal membrane. The gradual rise of S_0 with $[\text{K}]_s$ can be understood because the increase of $[\text{K}]_s$ depolarises the intracellular potential² and possibly leads to an increase of the cellular K^+ concentration. Consequently, the increased electrochemical gradient for K^+ across the mucosal membrane results in a rise in the K^+ efflux.

More evidence for the existence of K^+ -selective channels in the mucosal membrane was found in the following experiments. It is known that tetraethylammonium (TEA) blocks the K^+ channels in nerve membrane¹² and reduces the permeability of the mucosal membrane of the gallbladder¹. The addition of 5 mM TEA to the mucosal bathing solution completely

inhibited the lorentzian noise components (Fig. 1C). This was observed for the spontaneous lorentzian current fluctuations recorded with Na Ringer's on both sides, as well as in experiments where the lorentzian was produced by a K^+ gradient across the epithelium. The inhibitory effect of TEA occurred in less than 5 min and was completely reversible. Added to the serosal side, TEA had no effect on the fluctuations. This clearly demonstrates that the fluctuating K^+ channels are located on the mucosal side.

As the paracellular shunt path of the gallbladder has a high conductance¹³, especially for K^+ (ref. 2), we investigated the possibility that the fluctuations are caused by a K^+ flux through

Fig. 2 Plateau values, S_0 , as a function of the serosal ($[\text{K}]_s$) and mucosal ($[\text{K}]_m$) K^+ concentration. Na^+ was replaced by K^+ at constant ionic strength. Closed circles represent the K^+ replacements at the mucosal side with normal Ringer's on the serosal side. The open circles are data obtained with normal Ringer's on the mucosal side and with different $[\text{K}]_s$ values. At $[\text{K}]_m = 36 \text{ mM}$, S_0 was smaller than the amplifier noise level, which is about $1.0 \times 10^{-21} \text{ A}^2 \text{ s cm}^{-2}$. As the exact position of this point is unknown, it is indicated with dashed lines, s.e.m. values are indicated.

the shunt. The cationic permeability of the paracellular pathway can be decreased with the addition of 20 mM 2,4,6-triaminopyrimidine (TAP) to both sides of the epithelium¹⁴. With Na Ringer's on both sides, the transepithelial resistance increased in this series of experiments from 128 ± 20 to $355 \pm 38 \Omega \text{ cm}^2$ ($P < 0.0005$, $n = 8$). When all Na^+ was replaced on both sides by K^+ , an increase from 169 ± 46 to $251 \pm 67 \Omega \text{ cm}^2$ ($P < 0.01$, $n = 6$) was found. We therefore assume that TAP reduces the K^+ permeability of the paracellular shunt, as was shown for other cations¹⁴. The plateau values of the lorentzians recorded either with Na Ringer's on both sides, or in the presence of a K^+ gradient across the epithelium, did not change significantly with the addition of 20 mM TAP to both bathing solutions. Therefore, as TAP reduces the paracellular K^+ fluxes and does not change the lorentzian current fluctuations, it seems unlikely that the K^+ -selective structures are located in the paracellular pathway.

From our data, we conclude that K^+ -selective channels, which open and close randomly, exist in the mucosal membrane of the toad gallbladder. No rectification characteristics could be shown, as both an inward- and an outward-directed K^+ gradient across the mucosal membrane caused an increase of the lorentzian current fluctuations. TEA, as in other tissues, acts as a reversible blocker for the K^+ channels. Further investigations, which allow us to determine the probabilities for the open and closed state, can give an insight into the mechanism which controls the K^+ permeability.

We thank Mrs L. De Handschutter-Janssens for technical assistance.

Absence of measles proviral DNA in systemic lupus erythematosus

MEASLES VIRUS usually causes an acute self-limiting infection in humans and a productive cytolytic infection in susceptible tissue culture cells. However, measles-like virus has been isolated from the brains of patients with subacute sclerosing panencephalitis (SSPE), a chronic progressive neurological disorder of children¹. Also, persistent measles infection has been implicated in the pathogenesis of several chronic diseases of unknown aetiology, including multiple sclerosis² and systemic lupus erythematosus (SLE)³. Manipulation of the conditions of infection can result in persistently infected tissue culture cells, which have been proposed as a model system for studying the molecular mechanisms responsible for cytolytic virus persistence in man^{4–6}. There is experimental evidence for at least four mechanisms leading to the induction of persistent measles infections: the production of defective virus particles which interfere with the replication of complete virus⁷, the generation of mutant virus strains with the capacity for non-cytolytic replication⁸, and infection of certain cell types (for example, neurones) restricted in their capacity to support all steps in virus

replication⁹. Zhdanov *et al.*^{10–13} have proposed that measles virus persists in cells by a mechanism similar to that shown for retroviruses, that is, the synthesis of a DNA copy of the viral genome and the insertion of the proviral DNA into the host cell chromosome. This would be a novel mode of replication, as the replication of measles virus in cytolytic infections involves a double-stranded RNA intermediate. Using tritium-labelled viral RNA probes in molecular hybridisation assays, Zhdanov *et al.* have demonstrated the presence of measles virus-related DNA in chick embryo cells¹¹ and human lymphoid cells¹³ persistently infected with measles virus. Further, they detected measles virus-related DNA in leukocytes, lymph nodes, kidney and urine cell sediment from five SLE patients¹². Negative results were obtained using cells from appropriate control tissues. The obligative reverse transcriptase was found in the persistently infected cell lines and SLE tissues, and concomitant retrovirus infection was proposed as a prerequisite for persistent measles infection. Thus, these studies not only provide insights into the molecular mechanisms of measles virus persistence but suggest aetiological relationships for a fatal disease of unknown cause. However, we report here that, using a more sensitive nucleic acid hybridisation assay, we were unable to confirm the presence of measles virus-related DNA in either persistently infected cells or cells from patients with SLE.

We used a radioisotopically labelled complementary DNA probe (MV cDNA) generated from an *in vitro* reverse transcriptase reaction, using measles virus-specific mRNA as template and reverse transcriptase from avian myeloblastosis virus. Reaction conditions were selected to optimise the extent of transcription of the viral mRNA^{14,15}. The measles virus-specific mRNA (MV mRNA) used as template in this reaction was obtained by infecting CV-1 cells at a high multiplicity of infection and then treating the cells with actinomycin D and cycloheximide (for details see legend to Fig. 1). High concentrations of actinomycin D ($25 \mu\text{g ml}^{-1}$) are necessary for complete suppression of host cell RNA synthesis in infected cells¹⁶. Cycloheximide decreases virion RNA synthesis but increases the yield of viral mRNA¹⁷. Infected cells were ruptured and polyribosomes isolated by differential centrifugation. RNA was extracted from polyribosomes by caesium chloride centrifugation and poly-A-rich RNA purified by affinity chromatography. MV mRNA had a sedimentation coefficient of $\sim 20\text{S}$ in sucrose-SDS gradients and its separation into discrete species by formamide-polyacrylamide gel electrophoresis is reported elsewhere¹⁸.

MV ³H-cDNA was purified as described in the legend to Fig. 1. The cDNA was 93% single stranded, as determined by sensitivity to S_1 nuclease, and had a sedimentation coefficient of $\sim 7\text{S}$ in alkaline sucrose gradients¹⁹. Hybridisation of ³²P-labelled MV mRNA to excess MV ³H-cDNA (ratio 1:10) protected 90% of the labelled RNA from hydrolysis with RNase¹⁸. Further evidence of nearly complete transcription of the RNA template was found in the kinetics of annealing of the cDNA to the MV mRNA template (Fig. 1). The half-saturation value (C_{t1}) of the MV probe to its template was compared with the C_{t1} of polio cDNA annealed to polio virion RNA using the relationship described by Birnstiel *et al.*²⁰. A nearly complete DNA copy of polio RNA (98% of polio genome) was synthesised using the method of Kacian and Myers¹⁷. The kinetic complexity of MV mRNA was 2.3-fold greater than that of polio RNA. As the molecular weight of polio RNA is estimated to be $\sim 2.6 \times 10^6$ (ref. 21), the calculated complexity of MV mRNA of $\sim 6 \times 10^6$ is consistent with data obtained from sedimentation analysis of virion RNA²². The thermal stability of the measles virus mRNA-cDNA hybrid was analysed by hydroxyapatite chromatography; the T_m value was 87.5°C (temperature at which 50% of hybrid eluted from the column), indicating a high degree of base-pair matching²⁵.

The specificity of the viral cDNA probe was demonstrated by a series of hybridisation experiments shown in Table 1. There was minimal hybridisation to relevant synthetic homopolymers (rA, rG) and unrelated viral and bacterial RNA, and a small

degree of hybridisation to monkey kidney cell nucleic acid (<6%). It is likely that this results from *in vitro* transcription of normal cell mRNA contaminating the MV mRNA preparation used as template. If there is non-preferential transcription of viral and cell mRNA, the percentage of the cDNA hybridising to normal cell DNA represents the fraction of the template which is cell mRNA. This fraction has varied over ~3–20% using probes generated from different MV mRNA preparations. 87% of the probe hybridised to RNA from infected cells but there was only minimal hybridisation to DNA from either lytically or persistently infected cells. A higher degree of hybridisation to RNA from lytically infected cells probably did not occur because of the presence of unlabelled negative-strand (virion) RNA which competes with the probe for positive-strand viral mRNA in the hybridisation reaction. Removal of negative-strand viral RNA from the RNA preparation by oligo-dT cellulose chromatography increases the hybridisation of the probe to 94%.

We attempted to hybridise the MV cDNA probe to DNA from various organs (spleen, kidney, placenta) of 15 patients with SLE, and DNA from six normal individuals (that is, the organ demonstrated no histopathology). With the exception of four patients from whom placenta was obtained, all patients had aggressive disease and the majority of specimens were obtained at necropsy. The conditions of the annealing reactions were as described in the legend to Fig. 1. Annealing mixtures contained 210 µg of cell DNA and 400 pg of ³H-cDNA, and were incubated to a C_0t value of 5,000. We found that <5.2% of the probe hybridised to the DNA samples from SLE patients compared with 1.0–5.2% hybridisation to DNA from the same organs of normal controls. Similarly, there was no difference in cDNA–cell RNA hybridisation experiments using RNA from seven SLE patients and four normal controls in the same reaction conditions as those used in the DNA–DNA hybridisation reaction. 1.0–2.5% of the probe hybridised to RNA from SLE samples compared with 2.5–3.5% hybridisation to RNA from normal controls.

Therefore, the data described here do not support the findings of Zhdanov *et al.*^{10–13}. We were unable to find evidence of measles virus-related DNA sequences in persistently infected cell lines despite the use of a nucleic acid probe with 2 logs higher specific activity than that used in their studies. The persistently infected cell lines studied by Zhdanov *et al.* showed evidence of concomitant infection with a retrovirus, as determined by the presence of 70S RNA and reverse transcriptase. We could not detect evidence of retrovirus infection in our cell lines by assays

for viral reverse transcriptase²⁸, despite previous reports that some clones of HEP-2 cells contained type 'B' retrovirus²⁹. Differences in the expression of this retrovirus-specific enzyme by the cell line could determine whether other viral RNA molecules are transcribed into a DNA form and integrated.

Fig. 1 Hybridisation of viral RNAs to ³H-cDNA probes. MV mRNA (○) and polio virion RNA (●) were hybridised to their respective cDNA. CV-1 cells grown in monolayer in minimum essential media with 5% fetal calf serum (MEM-FCS) were infected with the Edmonston strain of measles virus at an MOI (multiplicity of infection) of 10, for 2 h at 37 °C. Four days after infection, media were replaced with fresh MEM containing 25 µg ml⁻¹ actinomycin D (Sigma). Two hours later cycloheximide (Sigma) was added to a final concentration of 75 µg ml⁻¹. Six hours after the addition of cycloheximide, the cells were removed from the flask with trypsin and centrifuged for 10 min at 200g. They were resuspended in a solution containing 10 mM Tris-HCl, pH 7.5, 10 mM NaCl, 1 mM MgCl₂ and 5% sucrose (TNM), and kept at 4 °C for 15 min. The cells were broken by 5–20 strokes of a tight glass Dounce homogeniser and cell disruption monitored by phase contrast microscopy. Nuclei were centrifuged for 10 min at 600g and the nuclear pellet washed once more with the hypotonic buffer. The post-nuclear pellet supernatants were pooled and layered on a discontinuous gradient containing 13.4 ml of 1 M sucrose (in TNM with 100 µg ml⁻¹ polyvinyl sulphate) over 4 ml of 2.5 M sucrose in an SW27 rotor and centrifuged at 27,000 r.p.m. for 3 h at 4 °C. The opalescent polyribosomal band at the interface of the two sucrose layers was removed by puncturing the side of the tube. The polyribosomal sample was then made to 0.5% SDS and 1 M mercaptoethanol and RNA extracted by the method of Glisin *et al.*²⁴. CsCl was added at 1 g per ml of sample, and the mixture shaken for 15 min, then layered on 1.5 ml of 5.7 M CsCl (in 0.1 mM EDTA) and centrifuged at 35,000 r.p.m. for 12 h in an SW50.1 rotor at 20 °C. The RNA pellet was resuspended in 0.01 M Tris-HCl, pH 7.5, 0.5 M NaCl and poly-A-rich RNA obtained by passing the sample twice through an oligo-dT cellulose column¹⁸. The eluate from the column was pooled, made to 0.4 M NaCl, precipitated with two volumes of ethanol, and the RNA used as template in a reverse transcriptase reaction. The total reaction (0.1 ml volume) contained 50 mM Tris-HCl, pH 8.3, 50 mM KCl, 8 mM MgCl₂, 0.5 mM dithiothreitol, 1 mM each of dATP, dTTP, dGTP and ³H-dCTP (29.3 Ci mmol⁻¹, New England Nuclear), 100 µg ml⁻¹ actinomycin D, 5 µg MV mRNA, 1 µg dT₁₀ and 5 units avian myeloblastosis reverse transcriptase. For poliovirus RNA templated reactions, 35S polio RNA was used¹⁵. The reaction was incubated for 1 h at 37 °C and terminated by the addition of 0.1 M EDTA. RNA was hydrolysed and ³H-cDNA purified by methods reported previously²⁵. The specific activity of the ³H-cDNA was calculated to be ~10⁷ c.p.m. per µg DNA. Hybridisation reactions were carried out in 20–40-µl volumes in glass capillaries. The reaction mixture contained 50 mM Tris-HCl, pH 7.0, 0.5 M NaCl, 1 mM EDTA, 0.1% sodium dodecyl sulphate (SDS), 0.2 µg of viral RNA (or total *E. coli* RNA) and 4,000 c.p.m. of ³H-cDNA probe. The polio cDNA was sheared to a size comparable with that of the MVm cDNA because of the effect of single-strand length on kinetic complexity³¹. Samples were heated to 100 °C for 2 min and incubated at 65 °C. Equivalent C_0t (product of RNA concentration, time of incubation and factor for cation concentration) was determined by the method of Britten and Kohne²⁶. S₁ nuclease analysis of the hybridisation reaction was by the method of Vogt²⁷.

Table 1 Hybridisation of MV ³H-cDNA to various nucleic acids

RNA	% Hybridised
Poly rA	<1%
Poly rG	<1%
Avian myeloblastosis virus	<1%
Newcastle disease virus	<1%
<i>Escherichia coli</i>	<1%
CV-1 cells	3.6%
CV-1 cells, MV-infected	87.0%
DNA	
<i>E. coli</i>	<1%
CV-1 cells	5.7%
CV-1 cells, MV-infected	4.6%
Hamster embryo cells, MV-infected	4.0%
HEP-2 cells, MV-infected	5.2%

The hamster embryo cell line⁶ and HEP-2 cell line³⁰ were persistently infected with MV. Both cell lines produced 10²–10³ plaque-forming units per ml per 24 h and >90% of cells haemadsorbed rhesus-monkey erythrocytes. Hybridisations were carried out as described in the legend to Fig. 1, and reactions with viral RNA were taken to a C_0t = 1 and those with cell RNA and DNA to a C_0t = 5,000 (ref. 26). DNA was extracted by a method described previously²⁵ and RNA extracted by the method of Glisin²⁴.

Scientists from all over the world, concerned with the diverse branches of hair research, will meet at the 1st International Congress of Hair Research in Hamburg. The objectives of this specialist Congress of Hair Research are: exchange of information, progress reports, outlooks.

Subjects of Congress

Plenary Sessions:

1. The Hair
2. The Hair Follicle and Keratinization
3. The Environment of the Hair Follicle
4. Control of Hair Growth
5. Hair Diseases
6. Treatment of Hair Diseases
7. Effects of Hair Care Products
8. Toxicology and Safety

Workshops:

1. Hair Surface
2. Principles of Hair Colouring
3. Methods of Testing Hair Care Products
4. Technics for Investigating Hair Properties

Also, we were unable to confirm the presence of measles virus DNA or RNA nucleotide sequences in cells from patients with SLE. Alekberova *et al.*¹¹ detected 2–5 measles virus gene equivalents per cell, well within the limits of sensitivity of our assay. In reconstruction experiments, we could unequivocally detect 1 viral gene equivalent per cell. One could construct an hypothesis for a viral cause of SLE in which few cells were infected and infected cells had a low level of viral gene expression. In this situation, viral information would escape detection by the hybridisation assays carried out in the present study. However, our findings, plus evidence of the non-viral nature of the tubulo-reticular structures in SLE and the nonspecificity of increased antiviral antibody titres in this disease³, indicate that it is unlikely that measles virus has a role in the pathogenesis of SLE. Collaborative studies which are now in progress through the USA/USSR Scientific Exchange programmes should clarify the discrepancy between the results reported here and those of Soviet investigators. Further, this study has shown that viral cDNA probes can be used to examine molecular aspects of measles virus replication and persistence, and may be useful in clarifying the role of measles virus in other human diseases, particularly multiple sclerosis.

We thank Drs Fred Rapp and John Rice for the persistently infected cell lines, and Dr Dan Kacian for polio RNA and J. Beard for avian myeloblastosis reverse transcriptase. This work was supported by grants from the National Multiple Sclerosis Society and the Arthritis Foundation.

Expression of endogenous C-type viral antigen on normal mouse haemopoietic stem cells

PARAMETERS such as size, density and differences in cell-cycle kinetics have been used to distinguish murine pluripotent haemopoietic stem cells (colony-forming units in the spleen, CFU-S) and committed haemopoietic progenitor cells¹. Efforts to use surface membrane markers^{2–4} have been based on two different, mutually exclusive concepts that regard pluripotent stem cells either as 'null-cells' or 'multiple-marked' cells. The first concept suggests that the markers are sequentially expressed during differentiation and maturation of a cell. Pluripotent stem cells, being the most undifferentiated haemopoietic cells, would be expected to have no markers or at least very few. According to the 'multiple-marked' stem cell hypothesis, however, differentiation would be accompanied by a specific loss of markers⁵. CFU-S can be detected by the development of spleen colonies after transplantation of normal syngeneic bone marrow cells (BMC) into irradiated recipients⁶. Committed granulocyte-macrophage colony-forming cells (GM-CFC) and early or late erythroid (BFU-E or CFU-E) progenitor cells can proliferate clonally in semisolid medium *in vitro* if stimulated by specific growth factors, namely granulocyte-macrophage colony-stimulating factor (GM-CSF) or erythropoietin^{7–9}. Pretreatment of normal marrow cells with a rabbit antiserum against mouse brain tissue has been reported to suppress spleen colony formation *in vitro* without influencing the growth of granulocyte-macrophage colonies *in vitro*¹⁰. We now report that antigens coded by endogenous C-type virus are expressed on pluripotent stem cells but were not detected on committed progenitor cells.

Our approach was suggested by recent experiments where an antiserum directed against endogenous xenotropic C-type virus suppressed the humoral immune response in all mouse strains tested^{11,12}. As immunocompetent cells are ultimately derived from pluripotent stem cells of the lymphoid and myeloid system¹³, it is conceivable that viral antigens are also expressed on cells of the haemopoietic system where they may have a physiological role, as suggested for cells participating in the immune response.

Fig. 1 Effect of preabsorption with virus on capacity of antiserum to suppress colony formation by haemopoietic stem cells. Marrow cells were incubated with medium or serum as described in the legend to Table 1. The final dilution of the serum was 1:80. 400 µg of density-gradient-purified virus was pelleted by centrifugation, incubated with 50 µl of serum diluted 1:10 for 60 min in ice and removed again by centrifugation. *a*, Medium control; *b*, xenotropic BALB/c virus absorbed antiserum. LPS-induced xenotropic BALB/c virus used for absorption was grown in mink cells (CCL-64); *c*, Friend leukaemia virus-absorbed antiserum; *d*, tobacco mosaic virus-absorbed antiserum; *e*, non-absorbed antiserum.

Table 1 Effect of pretreatment of marrow cells with anti-xenotropic virus serum on the number of CFU-S and GM-CFC

Marrow cells were flushed from the femurs of 12-week-old male SPF C57BL/6 mice with 1 ml RPMI 1640 medium (Microbiological Associates), supplemented with antibiotics and 0.02 M HEPES. Influence of antiserum on CFU-S: 2×10^6 viable nucleated cells were incubated at different dilutions of serum without complement (C') in a final volume of 0.4 ml at 0 °C. 30 min later the cells were diluted 1:25 with supplemented RPMI 1640 and washed. The cells were then injected intravenously into syngeneic mice pre-irradiated with 800 rad (10^5 viable nucleated cells per mouse, 15 mice per group). The spleens of the mice were removed 9 d later, fixed for 10 min in Boulin's fixative and the number of macroscopic colonies counted⁶. Influence of antiserum on GM-CFC: 3.2×10^5 viable nucleated cells were incubated with different dilutions of serum with or without complement in a final volume of 0.16 ml for 45 min at 37 °C and 7.5% CO₂. After three washings in the cold (5 min, 200g), aliquots of 1×10^5 cells were cultured in Petri dishes containing 1 ml of Dulbecco's modified Eagle's medium (Gibco) supplemented with antibiotics, and an amino acid-vitamin cocktail¹⁶ 15% horse serum (Microbiological Associates), 0.8% methylcellulose¹⁷ (Dow) and 5% mouse-lung-conditioned medium¹⁸ (representing a plateau concentration of GM-CSF) at 37 °C and 10% CO₂ in a humidified incubator. Colonies containing more than 50 cells were counted 7 d later. Each number represents the mean value of duplicate cultures. ND, not determined.

The antiserum used was from the same pool previously reported to be immunosuppressive^{11,12} and was prepared against BALB/c xenotropic endogenous C-type virus originally induced from spleen cell cultures by treatment with bacterial lipopolysaccharide (LPS)¹⁹ and collected in stably infected rabbit cornea (SIRC) cells.

To examine the effect of the antiserum on mouse CFU-S, normal marrow cells were incubated either with antiserum or control serum *in vitro*, washed and then injected into irradiated recipients. No exogenous complement was added, as it was assumed to be present in the recipients. A typical experiment (Table 1) showed that the development of spleen colonies was suppressed by pretreatment of the donor cells with antiserum. Suppression was not always complete, but with high concentrations of antiserum it was never less than 75%. In other experiments, marrow cells were incubated with antiserum and complement. After washing, cells were assayed for GM-CFC (Table 1). The antiserum did not inhibit colony development whether or not complement had been added.

In other experiments BFU-E and CFU-E frequencies were determined in marrow cells preincubated in identical conditions with combinations of antiserum, control serum and complement. Again, no influence could be detected (L. Guilbert and F.G.S., unpublished data). However, some experiments (data not shown) indicate that preincubation of spleen cells with antiserum and complement can efficiently suppress the frequency of B-lymphocyte colony-forming cells (BL-CFC). The failure of antiserum plus complement to reduce the number of colonies derived from GM-CFC or erythroid precursor cells does not definitely prove that these cells lack the corresponding antigen. The failure could also reflect low antigen density and consequent low antibody concentration on the cell-surface

insufficient to initiate complement activation. To clarify this, marrow cells were incubated with antiserum in the cold and subsequently with a goat anti-rabbit immunoglobulin (GARIG) and complement in the warm. The ability of the anti-immunoglobulin to bind complement, the lytic activity of the particular complement batch used and the efficiency of the procedure to detect low concentrations of cell-surface-bound antibody unable by itself to activate complement were tested in parallel in another system. Mouse thymus cells preincubated with a non-lytic dilution of a rabbit anti-mouse thymus cell serum were readily killed by a second incubation with GARIG plus complement. However, GM-CFC were not reduced by this procedure (Table 2). These data strongly suggest that GM-CFC do not bind significant amounts of antiviral antibodies, although

Table 2 Failure to detect endogenous viral antigen on GM-CFC by indirect cytotoxicity

Treatment of cells pre-sensitised with antiserum		Results	
GARIG (final dilution)	C'	BMC+anti-xenotropic virus serum (GM-CFC per 10 ⁵ BMC)	Thymus cells + antithymus cell serum (% cytotoxicity)

1:80	—	78	5
1:80	+	92	96

Indirect cytotoxicity for GM-CFC: marrow cells were prepared and handled during the first step as described in the legend to Table 1, but incubated with a 1:20 dilution of anti-xenotropic virus serum for 30 min at 0 °C. The cells were then washed twice (5 min, 200g) in the cold and incubated for 45 min at 37 °C and 7.5% CO₂ in air with GARIG (Behringwerke) and complement. After two further washings with the medium, the cells were assayed for GM-CFC as described in the legend to Table 1. Each number is the mean value of duplicate cultures. Indirect cytotoxicity test for thymus cells: C57BL/6 thymus cells were prepared by standard techniques in RPMI 1640 supplemented with 2% FCS. Aliquots of 5×10^5 cells were incubated with rabbit anti-mouse thymus cell serum in a volume of 0.05 ml and a final dilution of 1:2,560 for 30 min at 0 °C in microtitre plates. 30 min later 0.1 ml of medium was added and the cells washed twice in the cold. The cells were resuspended in 0.05 ml of medium containing GARIG and complement. After a second incubation for 45 min at 37 °C, the percentage of killed cells was determined by Trypan blue dye exclusion. A minimum of 200 cells were counted per sample.

an extreme resistance to complement-mediated cytolysis cannot definitely be excluded. Support for the view that the antiserum does not react with GM-CFC was obtained when the IgG fraction of the antiserum was added directly to the culture dishes. This procedure did not influence GM-CFC but it effectively inhibited the growth of BL-CFC (data not shown).

To prove that the inhibitory effect of the antiserum on spleen colony formation was due to its antiviral specificity, absorption experiments were carried out with equal amounts of different viruses. To exclude co-absorption of possible reactivities against rabbit cell-membrane antigens, xenotropic C-type virus used for absorption was grown in mink rather than rabbit cells, and was found to neutralise the activity of the antiserum completely. Preabsorption with Friend virus was almost as effective. This was expected, as Friend virus also neutralised the immunosuppressive activity of this serum¹². Cross-reactivity between Friend and BALB/c xenotropic virus is consistent with the claim that the Friend virus genome contains sequences derived from endogenous xenotropic virus¹⁴. On the other hand, tobacco mosaic virus, an unrelated virus, had no ability to reduce anti-stem-cell activity of the serum (Fig. 1).

The data presented here show that an antiserum against endogenous C-type virus suppresses the development of spleen colonies generated by pluripotent haemopoietic stem cells. On the other hand, the antiserum displayed no detectable effect on GM-CFC and erythroid precursor cells. The most likely explanation for the observed effect is that stem cells express viral antigen and are killed *in vivo* by a mechanism involving the Fc portion of bound antibodies and possibly complement. It is tempting to speculate that endogenous viral antigens are physiologically required for the differentiation of haemopoietic cells in a similar way to that suggested for cells differentiating during an immune response^{11,12,15}. It is interesting that (Fab')₂ fragments of the antibody used have been found to suppress an *in vitro* immune response demonstrating complement independence of the phenomenon (C.M. and G. Schumann, unpublished results). This serum may be useful for understanding haemopoiesis.

We thank Dr P. Dukor for discussions and Dr D. Metcalf for assistance with the manuscript. F.G.S. is supported by the Deutsche Forschungsgemeinschaft. Part of this study was carried out during his postdoctoral fellowship at CIBA-Geigy.

Certain rheumatoid factors react with nucleosomes

NATURAL antibodies against antigenic sites on the Fc region of human and animal IgG are referred to collectively as rheumatoid factors (RF) and they represent one of the immunological hallmarks of rheumatoid arthritis (RA). Thus, the synovial fluid and tissue of RA patients contain large immune complexes which at least in part consist of RF¹⁻⁴, and RF are present in serum in the majority of patients with definite or classical RA. Recent studies have demonstrated that purified and pepsin-digested polyclonal RF of IgG class from an RA serum (Han), in addition to reacting specifically with IgG, also bind to an antigen associated with cell nuclei from many species⁵. Furthermore, essentially 100% of the anti-nuclear antibodies (ANA) of two sera (Han, Jos) was absorbed by insolubilised human IgG; the

antibodies which could be eluted from this immunosorbant bound to cell nuclei, and this binding was specifically inhibited by Fc fragments of human IgG^{5,6}. We show here that RF from serum Jos bind to nucleosomes, the repeating histone-DNA subunit of chromatin.

Mono-, oligo- and polynucleosomes were prepared by nuclease digestion of chicken erythrocyte nuclei (see legend to Fig. 1). Chicken red cells were chosen because contamination with immunoglobulins (Ig) could be avoided by washing. Nucleosomes in the nuclear digest were fractionated into two major pools by gel filtration on Sepharose 4B (Fig. 1). Pool 1 and the 150 mM NaCl-insoluble fraction of pool 2 contained all the major histone classes (Fig. 1b, d) and essentially no non-histone proteins (Fig. 1e, f). DNA from pool 1 formed a series of bands consistent with the presence of multiples of the 200 base pair monomer DNA (Fig. 1g). The size of the DNA from pool 2 corresponded roughly to nucleosome monomers and dimers (Fig. 1i). Sepharose 4B gel filtration in 0.6 M NaCl stripped the chromatin of H1 and H5, but H2a, H2b, H3 and H4 were still present (Fig. 1c).

The nucleosomes of pools 1 and 2 were tested for their ability to absorb RF specifically. Serum Jos, which contains RF with high avidity for cell nuclei⁶, and serum Ter whose RF lack ANA activity, were used for this experiment (Fig. 2). Both pool 1 (oligo- and polynucleosomes) and pool 2 (mono- and dinucleosomes) absorbed RF from serum Jos, but not from serum Ter (Fig. 2). At saturation about 85% of RF Jos was removed; this required 0.6 µg of DNA from pool 1 and 150 µg of DNA from pool 2 (Fig. 2).

In this experiment it was possible that serum IgG bound to nucleosomes and that RF reacted with bound IgG rather than with the nucleosomes themselves. IgM from serum Jos was therefore prepared (see legend to Fig. 2). A solid phase radioimmunoassay using immunospecifically purified ¹²⁵I-labelled rabbit anti-human H(γ) chain antibodies showed that the IgM preparation contained only 0.6% IgG. Nevertheless, the two nucleosome pools absorbed the same proportion (~85% at saturation) of RF from IgM as from diluted serum (Fig. 2). As the amount of IgM used was 11.5 µg, only 69 ng (0.6%) of IgG was present. From earlier studies it is known that about 25% of IgM in serum Jos is RF⁶. This means that 2,400 ng (2.6 × 10⁻¹² mol) of IgM-RF would have to be absorbed by 69 ng (0.46 × 10⁻¹² mol) of IgG, assuming that all IgG were bound to nucleosomes and thereby rendered insoluble in 150 mM NaCl. Both these events are very unlikely, and it is therefore concluded that RF Jos do indeed bind directly to nucleosomes. Further tests supported this conclusion, as nucleosomes (pool 2) absorbed 82% of RF Jos isolated immunospecifically by elution from human IgG insolubilised on beaded Sepharose. Thus, the same proportion of RF was removed from serum, the IgM and the isolated RF fraction.

To determine whether the antigenic determinant on nucleosomes which was recognised by RF Jos required the presence of histones H1 and H5, polynucleosomes stripped of H1 and H5 were prepared (see Fig. 1b and legend to Fig. 1). This material (150 µg as DNA) which was soluble in phosphate-buffered saline (PBS), displaced 87% and 77% of RF derived from serum and IgM Jos, respectively, but none of the RF from serum Ter (Table 1). By contrast, when 1,180 µg of deproteinised double-stranded calf thymus DNA with an average size of 160 base pairs was mixed with IgM Jos (5.55 µg), only 20% of RF was displaced; this value is at the significance limit for the assay. Evidently, the determinant for crossreacting RF Jos is present on the nucleosome core which consists of DNA plus H2a, H2b, H3 and H4.

The polynucleosomes of pool 1 absorbed no anti-blood-group I activity from an isolated monoclonal IgM(κ) cold agglutinin (data not shown). This result, together with their lack of binding of RF from serum Ter, supported the conclusion that RF Jos reacted specifically with the nucleosomes.

The radioimmunoassay for RF depended on the reaction of labelled rabbit anti-human L-chain antibody with RF bound to

IgG on the tube wall. It could be argued that the labelled rabbit antibodies did not bind to RF with their active sites but with their Fc regions, which might function as an antigen for RF bound on the tube wall. However, addition of a 1,000-fold excess of nonspecific 'cold' rabbit IgG in the second step of the reaction decreased binding of ^{125}I -anti-L-chain antibody by only 5% which ruled out this objection.

The present results confirm that RF Jos recognise a nuclear antigen in addition to IgG, and establish that the majority (85%) of these polyclonal RF belong to the crossreacting population. Furthermore, the data indicate that the nuclear antigen is found on a complex consisting of DNA and the four core histones H2a, H2b, H3 and H4. This conclusion is based on the following observations. About 2,400 ng of IgM RF (2.6×10^{-12} mol) was absorbed by only 600 ng (with respect to DNA) of nucleosome pool 1 (Fig. 2); this corresponds to 6×10^{-12} mol of DNA with a size of 200 base pairs, which is the DNA content in the monomeric nucleosome¹². This nucleosome fraction contained only a trace of non-histone proteins (Fig. 1e), it still bound RF after H1 and H5 had been removed (Table 1), and RF Jos did not bind to native DNA alone⁶.

The structural basis for this remarkable crossreaction is still unclear. There has been no report showing homology between sequences of the Fc(γ) region and any of the existing histones, although some similarity has been proposed between a phylogenetically ancient H4 peptide and certain V-region sequences shared by human κ and λ Ig L-chains¹³.

However, as human L-chains do not displace RF Jos from nuclei while Fc(γ) does⁶, this homology cannot explain the

Table 1 H1 + H5 stripped polynucleosomes bear antigenic determinant for rheumatoid factors (RF) in serum Jos

Antibody	H1 + H5 stripped nucleosomes*	RF bound (c.p.m.)	RF displaced† (%)
Serum Jos 1/800	—	21,899	—
Serum Jos 1/800	+	13,366	87.5
IgM Jos 11.5 μg	—	13,931	—

0.15 ml (150 μg) of H1 + H5 stripped polynucleosomes in PBS, pH 7.0, was mixed with 1.1 ml antibody dilution in PBS containing 1% BSA, and incubated for 2.5 h at room temperature. The mixture was then assayed for RF activity, and the % displacement calculated as described in the legend to Fig. 2.

* Chromatin fragments subjected to gel filtration in 0.6 M NaCl (see legend to Fig. 1).

† Based on comparison of c.p.m. bound by dilutions of the RF preparation in the absence of inhibitor (see legend to Fig. 2 for RF assay).

crossreaction. It is also unlikely that the determinant is a carbohydrate, as histones are not glycosylated. Possibly the two determinants recognised by the polyclonal RF Jos do not display that close structural similarity which past experience with cross-reacting antigens would lead one to expect. This is apparently the case for the polyclonal rabbit antibodies induced by immunisation with the hapten dinitrophenol, a large proportion of which crossreacts with menadione (vitamin K3)¹⁴; in this instance, the structural similarity between the two haptens is

Fig. 1 Sepharose 4B gel filtration of chromatin extracted from micrococcal nuclease-digested chicken red cell nuclei. Adult chicken red cells were washed three times and nuclei prepared according to Shaw *et al.*⁷. The nuclei were resuspended in digestion buffer (0.3 M sucrose, 0.01 M Tris-HCl, 0.75 mM CaCl_2 , pH 7.2) to give $A_{260} = 70$ (read as diluted in 0.1 M NaOH) and digested for 10 min at 37°C with 20 units of micrococcal nuclease (Worthington) per 24 A_{260} units. The digestion was terminated by addition of disodium EDTA to a final concentration of 0.01 M and chilling samples in an ice bath. The suspension was centrifuged at 12,000g for 15 min. The pellet was resuspended in 0.2 mM EDTA, pH 7.0, incubated overnight at 4°C and centrifuged at 10,000g for 10 min. The extracted chromatin fragments of the supernatant were subjected to gel filtration on Sepharose 4B (7 ml supernatant containing 455 A_{260} units on a 2.5×75 cm column equilibrated with 10 mM Tris-HCl, 0.2 mM EDTA, pH 7.4). The fractions (5 ml) were pooled as indicated by the horizontal bars and concentrated by negative pressure filtration. 96% of pool 1 was insoluble in 150 mM NaCl. Of pool 2, 60% was insoluble in 150 mM NaCl, and only this fraction was used; it was redissolved in 2 mM EDTA and dialysed against 0.2 mM EDTA, pH 7.0. Another 7-ml aliquot of the supernatant was fractionated on the same Sepharose 4B column, now equilibrated with 0.6 M NaCl, 10 mM Tris-HCl, 0.2 mM EDTA, pH 7.4. The elution profile (a) was almost identical to that shown with the low ionic strength buffer; fractions corresponding to pool 1 were dialysed against PBS. DNA from the various pools was extracted with an equal volume of redistilled phenol saturated with H_2O . b, c and d show the histone composition of pool 1 (b), pool 1 from 0.6 M NaCl gel filtration (c), and 150 mM NaCl insoluble pool 2 (d). Sodium dodecyl sulphate (SDS)-polyacrylamide gel electrophoresis was carried out⁸. e, f show the purity of pool 1 (e) and 150 mM NaCl-insoluble pool 2 (f) analysed on SDS-7.5% polyacrylamide gels⁹ loaded with 60 μg (with respect to DNA) sample and stained with Coomassie blue; g, h, i show DNA fragment sizes of pool 1 (g), *HincII* digest of DNA from phage X174 (New England Biolabs) (h) and 150 mM NaCl-insoluble pool 2 (i). Electrophoresis of DNA was carried out in 1.4% agarose slab gels¹⁰ containing 40 mM Tris, 5 mM acetate, 1 mM EDTA, pH 7.9, and DNA bands were stained with ethidium bromide 1 $\mu\text{g ml}^{-1}$.

Fig. 2 Specific absorption of rheumatoid factor (RF) from serum Jos and IgM Jos by nucleosomes. IgM was prepared by gel filtration of serum on Sephadex G-200 equilibrated in 0.5 M NaCl, 0.2 M acetate, pH 4.0; the first three fractions of the breakthrough peak were pooled, and dialysed against PBS pH 7.2. Absorption of RF was effected by mixing the indicated amount of nucleosomes in 80 μ l of 0.2 mM EDTA, pH 7.0, with 1 ml of serum or IgM diluted in PBS containing 1% bovine serum albumin (PBSA). The solution turned slightly turbid immediately on addition of the nucleosomes. After incubation at room temperature for 2.5 h, the insoluble nucleosomes were sedimented by centrifugation. The supernatants were assayed for RF activity by a solid phase radioimmunoassay¹¹ using plastic tubes (Falcon 2052) precoated with rabbit IgG. The second antibody was immunoadfinity isolated ¹²⁵I-labelled rabbit anti-human L-chain antibodies. The incubation time for the first and the second antibody was extended to 18–24 h. The amount of RF absorbed by the nucleosomes was determined from standard curves obtained by making twofold dilutions of the RF-containing sample in PBSA. Absorption of 75% of RF thus corresponds to the radioactive antibody bound by a standard sample diluted fourfold. $\circ$, serum Jos diluted 1/800 + nucleosome pool 1; Δ , serum Jos 1/800 + pool 2; $\bullet$, IgM Jos (11.5 μ g) + pool 1; $\blacktriangle$, IgM Jos (11.5 μ g) + pool 2; $\square$, serum Ter 1/200 + pool 1; $\times$, serum Ter 1/200 + pool 2.

limited¹⁵ and hydrophobicity may be an essential shared component. A few homogeneous myeloma proteins and Waldenstrom macroglobulins with antigen-binding activity have also been found to possess more than one specificity^{15–16}. Thus, RF Jos and similar RF detected in other sera^{5,6} may be examples of 'polyfunctional' antibodies.

The crossreacting RF described in the present report emphasizes the general problem of extrapolating from the specificity of natural antibodies to the original antigenic stimulus which elicited their production. Moreover, the observations indicate that caution should be exercised in the interpretation of test results where RF are used as reagents, for example in detection of immune complexes.

We thank Drs M. K. Cowman and G. D. Fasman for discussions, and Dr M. H. Malamy for assistance with electrophoresis of DNA. This work was supported by a grant from the Norwegian Research Council for Science and the Humanities to K.H. and by an NSF grant to B.D.S.

Hydrophobic character of amino acid residues in globular proteins

PREDICTIVE studies on the secondary structure of globular proteins aimed at locating ordered structural segments have provided little information about spatial orientations or even as to whether residues are exposed or buried. However, the physico-chemical properties¹ of residues can be used to obtain such information. In particular the hydrophobic character², is a useful parameter in these studies. The hydrophobic character as defined by the indices given by Tanford³ and Jones⁴ does not reflect hydrophobic environment within protein structures, but we introduce here a new parameter, the 'bulk hydrophobic character' obtained from an analysis of the surrounding hydrophobic environment of amino acid residues in protein crystals. This is a better index of protein hydrophobicity, showing very good correlation with the extent to which residues are buried⁵ (correlation coefficient $r = 0.9$) compared with the hydrophobic indices used previously, and it could be used to characterise tertiary structures.

Our study is based on crystallographic data on 14 protein molecules (myoglobin, ribonuclease S, cytochrome *c*, lysozyme, staphylococcal nuclease, carboxypeptidase A, subtilisin BPN', α -chymotrypsin, carp myogen, cytochrome *b*₅, apolactate dehydrogenase, trypsin inhibitor complex, concanavalin A and flavodoxin; see ref. 6 for further details on these proteins). They include representative examples of all known characteristic structural types of proteins defined by Levitt and Chothia⁷.

We demonstrated previously⁶ that a sphere of 8 Å radius has the required volume for any one residue of a protein molecule for a study of the influence of the surrounding environment. In this report, therefore, we define the 'surrounding hydrophobicity' of a residue as the sum of the hydrophobic indices assigned to the various residues that appear within an 8 Å radius volume in the protein crystal. This parameter is given by:

$$H_i = \sum_{j=1}^{20} L_{ij} h_j$$

where L_{ij} is the total number of surrounding residues of the i th type associated with the j th residue in a given protein, and h_j is the hydrophobicity index for the j th residue. All the H values that belong to the same type of residue in the 14 crystals have been grouped together, and the arithmetic average ($\bar{H}$) for each type has been calculated. These average surrounding hydrophobicities are given in Table 1, together with the corresponding individual hydrophobic indices given by Tanford³ and Jones⁴. These ($\bar{H}$) values reflect the preferred hydrophobic environments for the residues and hence their 'bulk hydrophobic character'.

Table 1 Average surrounding hydrophobicities and the hydrophobicity indices for 20 amino acid residues occurring in globular proteins

Residue	Average surrounding hydrophobicity (H) (kcal)	Hydrophobicity index (h_i) (kcal)
Ala	12.97	0.87
Asp	10.85	0.66
Cys	14.63	1.52
Glu	11.89	0.67
Phe	14.00	2.87
Gly	12.43	0.10
His	12.16	0.87
Ile	15.67	3.15
Lys	11.36	1.64
Leu	14.90	2.17
Met	14.39	1.67
Asn	11.42	0.09
Pro	11.37	2.77
Gln	11.76	0.00
Arg	11.72	0.85
Ser	11.23	0.07
Thr	11.69	0.07
Val	15.71	1.87
Trp	13.93	3.77
Tyr	13.42	2.67

In Fig. 1 the individual hydrophobic index (heavy line) is compared with the corresponding preferred surrounding hydrophobicity (thin line) standardised with respect to Gln. Both Fig. 1 and Table 1 show that the surrounding hydrophobicity is not proportional to the corresponding hydrophobic index of the residue. Taking the actual values given in Table 1, the residues can be divided into three groups: Cys, Phe, Ile, Leu, Met, and Val with (H) values greater than 14.0 kcal belong to group I. Gly, Ala, His, Trp and Tyr fall into group II with (H) values between 12.0 and 14.0 and are thus less hydrophobic than group I residues, and the remaining residues Asp, Glu, Lys, Asn, Pro, Gln, Arg, Ser and Thr with values below 12.0 kcal belong to group III. Val and Ile have the highest surrounding hydrophobicity, with Leu, Cys and Met coming next in order. Though Val is less nonpolar than residues such as Ile, Phe and Trp when defined by thermodynamic transfer measurements according to Tanford, the average surrounding hydrophobicity value suggests that this residue can easily be accommodated inside the molecule. The low value of (H) for Trp and Tyr indicate that one polar atom even in a large nonpolar side chain is sufficient to cause a large reduction in the hydrophobic environment. When considering the residues in group III, it is important to note that the surrounding hydrophobicity of Pro lies within the range observed for the polar residues. As the characteristic structure of proline does not allow it to occur in

either β strands or helices except at the N terminus, it is restricted to loops that inevitably lie on the surface thus lowering the surrounding hydrophobicity. Of the polar residues Gln, Glu and Arg have higher hydrophobicities, and the preferred environments for the charged residues Asp and Lys are associated with the lowest surrounding hydrophobicities.

Our results show that Val with an hydrophobic index almost half that of Trp, has the highest surrounding hydrophobicity. On the other hand, the surrounding hydrophobicity of Trp is very much reduced even though this residue appears at the top of the hydrophobicity index scale. The same conditions prevail for residues Tyr and Pro which, in spite of high hydrophobic indices, exhibit surrounding hydrophobicities similar to those of more polar residues. These observations suggest that apart from the nonpolarity indicated by the hydrophobic indices of amino acid residue side chains, both their structure and the presence of some polar atoms strongly influence their bulk hydrophobic character and hence their spatial position in protein molecules. Surfaces of globular proteins often contain several nonpolar residues^{1,2}, mainly group II residues. In our earlier report³ we pointed out that surface nonpolar residues occur as short distorted α -helical and extended structural domains (one to three residues long) with the backbone polar atoms having high solvent accessibility. The (H) parameter therefore characterises the hydrophobic environment preferred by each amino acid residue in a globular protein and we suggest that this specific preference for each residue is an important factor in the folding of a linear chain into a globular shape. We are now studying applications of this parameter to protein folding.

Nature Index and Binders

The complete Index for 1977 is available, price £2.50 (UK), US\$5.00 (Rest of World). Copies of the 1976 index are still on sale, prices as above.

Binders for the journal are also available at £8.00 (UK), US\$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, UK.

Does BIOSIS have a "COLLECTIVE" Index? Yes, we do. It's on microfilm.

Integrated 5-year cumulations of Author, Subject and Biosystematic (Taxonomic) Indexes to Biological Abstracts are available now for retrospective searching of the life science literature.

- 3 cumulations: BA Vol. 34-45 (1959-64), Vol. 46-50 (1965-69), Vol. 51-58 (1970-74) — simplex cine mode
- 16mm silver halide film
- As cartridges or reels

Also on film — Annual Indexes for BA Vol. 1-33 (1927-59) and the complete abstracts file, from 1926 to right now.

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION
SWISS ACADEMY OF SCIENCES SWISS NATIONALFONDS

WORKSHOP ON

THE MOLECULAR BIOLOGY OF THE GENE

DAVOS (SWITZERLAND) MARCH 18-22, 1979

It is the aim of the workshop to discuss the organization of the eukaryotic genome, the structure, transcription and regulation of the eukaryotic gene unit.

In addition to the invited speakers, 50 scientists will be admitted. Participants will have an opportunity of presenting and discussing their work at a special poster session. A limited number of travel stipends will be available.

Those wishing to attend, please apply before December 15th, 1978 to one of the organizers. Since participation will be restricted to those actively engaged in gene research, a short curriculum vitae and a 100-200 word summary of the present research will be required.

Participants who have accepted the invitation to date include:

P. Berg, Stanford; R. Braun, Bern; S. Brenner, Cambridge; P. Chambon, Strasbourg; S. Clarkson, Geneva; B. Daneholt, Stockholm; J. Darnell, New York; E. Davidson, Pasadena; R. Flavell, Amsterdam; R. Fritel, La Jolla; W. Gehring, Basel; G. Georgiev, Moscow; W. Gilbert, Cambridge, Mass.; D. Glover, London; H. Goodman, San Francisco; B. Hall, Seattle; D. Hogness, Stanford; F. Kafatos, Cambridge, Mass.; L. Kedes, Palo Alto; H. Klenow, Copenhagen; R. Laskey, Cambridge; J. Paul, Glasgow; L. Philipson, Uppsala; R. Reeder, Baltimore; R. Roeder, St. Louis; H. Seedler, Freiburg; W. Schaffner, Zürich; P. Starlinger, Köln; J. Watson, Cold Spring Harbor; C. Weissmann, Zürich; H. Zachau, München.

ANALYSIS 79

Automation in Industrial and Clinical Chemistry

The next Analysis conference will be held at The City University, London on 16th-18th July, 1979.

This conference will focus attention on the cross-fertilization of ideas and concepts of automation between workers in clinical, industrial and academic environments.

Automation implies a system approach that can be applied at all levels of the analytical procedure and when applied in a complete sense has in addition to a technical and scientific impact an influence on managerial, organisational and economic considerations. The conference will focus attention on all these aspects within the general framework of the following sessions

- Education
- New Instrumentation
- Costing and Management
- Applications
- Standardisation

The programme committee comprising Dr. Peter Stockwell, Dr. Fred Mitchell, Derrick Porter and Fred Fearn, have invited an international team of authoritative speakers to provide the keynote lectures and to chair the various sessions. Whilst the majority of speakers have been invited, there will be sessions for short, submitted papers. Authors wishing to present papers in these areas should submit abstracts for consideration by the programme committee before 30th November 1978.

For further details on Analysis 79 contact Beverly Humphrey, Scientific Symposia Ltd., 33/35 Bowling Green Lane, London EC1R 0DA. Tel: 01-837 1212.

Fenland ecology

Peter D. Moore

Fenland: Its Ancient Past and Uncertain Future. By Sir Harry Godwin. Pp. 196. (Cambridge University Press: London and Cambridge, 1978.) £7.95.

THERE is no better living demonstration of the interaction of man with the natural environment anywhere in Britain than in the fenlands of East Anglia. Throughout prehistory and history these extensive tracts of swamp-land and bog have proved both a limitation on human mobility and settlement and, in more recent times, a valuable agricultural resource. A number of books, especially those of H. C. Darby, have considered man's conflict and symbiosis with fenland, particularly from the historical geography point of view, but this book approaches the subject from the biological angle.

In this sphere, Sir Harry Godwin is the ideal person to write such a book, for the story of the unravelling of fenland's history is essentially Godwin's autobiography. Indeed, the book has a strongly autobiographical, almost anecdotal style. It is written in an informal manner for a general readership; it avoids technical terms and jargon and does not carry references in the text, although a reading list is given at the end. This makes it easy, even exciting reading, which should prove attractive to students.

One advantage of the relaxed style is that we are provided with some rare glimpses into those chance events in history which have profoundly influenced the development of ecology in this country. Take, for example, that priceless sentence which introduces the chapter on pollen analysis, "In 1931, following a suggestion from A. G. Tansley, my wife began research in pollen analysis, a technique recently brought to notice by the Swede G. E. Erdtman . . .". It is difficult now to assess the full consequences of Tansley's chance remark.

Much of the book is concerned with the stratigraphy and palaeoecology of the fenland sediments. Rooted in the basal clays of the fens at many sites were found the preserved remains of giant bog oaks, many having dimensions far exceeding those found commonly in modern British forests; often they were over 27 metres in height.

These were inundated and killed by rising water tables as the true fens were formed. Subsequently, further woodland of a swampy nature developed over the reed bed sediments, and the sequence of species in these fen woods, leading ultimately to the establishment of pine, is of particular interest, for one finds similar developments on the other side of the North Sea and in some of the west coast submerged forests, as at Borth and Ynyslas, Dyfed.

The archaeological interest of the fenland peats is again introduced by a personal reminiscence: "I recall picking out (from the borer) what I took to be a bit of pine bark: licking it clean of peat . . . it shewed itself to be a struck flake of flint." Thus began the excavations of Shippea Hill and Peacock's Farm in fenland, now classic archaeological sites.

One of the most interesting questions in peatland ecology raised by Godwin's fen studies, is the extent to which true raised bog communities once flourished in the east of Britain. Peat cutting and agricultural developments have destroyed much of the evidence of past acidification of the fen systems leading to bog formation. At Woodwalton Fen, Godwin describes the surviving stratigraphic evidence for this process and at this site there still remain some frag-

ments of a relict, acidophilic community on the surface.

The latter part of the book concentrates on the hand of man in the modification of the fenland environment, and on the habitats and species lost as a result of exploitation. Perhaps the most important message of this book as far as mire conservation is concerned is the vulnerability of the ombrotrophic, raised mire system. The loss of this habitat in eastern England cannot be repaired; such a late stage in mire succession takes millennia to develop and the lesson of the fens should serve as a warning to those concerned with mire conservation in northern and western Britain, where similar exploitation is now occurring and where similar consequences are to be feared.

This book is essentially a compilation of scattered, largely previously published material, which is presented in a lucid, informal and readable manner. It is not so much a textbook as a personal view of a distinctive part of Britain and of the development of a field of environmental research in which the author has himself played the leading role. □

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences at King's College, University of London, UK.

Mathematical models in immunology

Theoretical Immunology. Edited by G. I. Bell, A. S. Perelson and G. H. Pimbley, Jr. (Marcel Dekker: New York and Basel, 1978.) Sfr. 128.

GEORGE BELL'S mass action model of the immune response made it respectable to use computer simulation in immunology. Now eight years later we have an opportunity to see how the field has progressed. This volume provides the first way of doing this conveniently, and as such can be recommended to professionals and general students. Although multi-authored, it is not a miscellaneous collection, but has a logical sequence with useful introduction and indexes. Several of the papers come from Bell's

own group of renegade theoretical physicists at Los Alamos.

As judged from this collection, mathematical models contribute more to immunology than to, say, embryology, and less than to fisheries research. Reasonable assumptions about lymphocyte triggering and regulation generate models which fit well empirical data on affinity maturation, high and low zone tolerance, and cycling antibody production. The models seem to be flexible to an extent which augurs well for the future as new phenomena are discovered, but which makes one a little uneasy at present. Thus, some models run quite satisfactorily without network suppression (Bruni, Mohler), whereas others depend on this entirely (Richter, Hoffman). Another difficulty is that in their latest version as expounded here, some of the models have grown mathematically rather

baroque.

A second group of theories deal with useful treatments of the MIF and Jerne plaque assays, the latter showing that several assumptions commonly made by experimentalists are probably wrong. Some common cook-book analysis—for example, of antibody affinity—is omitted. A third group deal with local phenomena: B cell triggering, cell recruitment (including a particularly elegant treatment of lymphocyte traffic), and antibody fit. Inman's handling of the antibody fit-frequency relationship improves on but

omits reference to my earlier work.

The weakest part comes from the experimentalists, who should have provided balanced reviews. Dual recognition is not as obscure as Burnet and Dutton make out, but does provide a problem for helper factors which Feldmann skips. The networkers have yet to take up Raff's challenge (*Nature*, 265, 205; 1977).

N. A. Mitchison is Professor in the Tumour Immunology Unit, Department of Zoology, University of London, UK.

Barley handbook

Barley. By D. E. Briggs. Pp. 612. (Chapman and Hall: London, 1978.) £25.

BARLEY is one of those crops, like wheat or cotton, with a fascinating biology and a complicated technology to match. Dennis Briggs makes a valiant attempt at a monographic treatment of all aspects of this, the world's fourth most important cereal crop. His book is a useful addition to the literature, although almost inevitably it suffers from unevenness.

The book begins with chapters on the morphology of the vegetative and reproductive plant. These are welcome, although it is unfortunate that the relevance and quality of some of the diagrams, often taken from rather elderly works, is doubtful; a page of illustrations of types of hood found in barley seems excessive, and better drawings, or even scanning electron micrographs, of the developing ear would have been valuable. The origin and classification of barley is discussed in a brief chapter and barley genetics are considered as a prelude to a chapter on crop improvement. To a non-specialist the treatment seems rather superficial, but a great deal of the recent literature is quoted, and this is a feature of the book as a whole.

Three chapters on barley biochemistry, grain quality and germination, and growth of the barley plant occupy about a third of the book. They are informative and give a comprehensive picture of almost every aspect of barley development and metabolism, at the price of being rather unselective and presenting biochemical pathways in somewhat exhaustive detail.

Agricultural aspects of the barley crop take up five chapters. That on agricultural practices and yield is brief and on occasions rather trivial. It is complemented by chapters on weeds, pests and diseases, and problems of

storage. Here one looks in vain for data on estimates of crop losses due to plant and insect pests, but perhaps in consolation we are given a formidable list of diseases carried by the rat. This rather unsatisfactory section also includes a chapter on production and harvesting machinery which is of doubtful value. No-one is going to go

Diatomic molecules

Diatomic Molecules: Results of Ab Initio Calculations. By R. S. Mulliken and W. C. Ermler. Pp. 197. (Academic: New York, San Francisco and London, 1978). \$19.50.

It seems churlish to greet any publication which has Robert Mulliken as an author with something less than total enthusiasm. His contributions to molecular physics have been truly monumental and his personality has inspired affection in those who know the man and his work. The choice of topic for this book again raises high expectations.

Diatomic molecules have always been wonderful model systems on which to base and test theories. Their spectroscopy is so rich and the results are so accurate and unambiguous that they have always attracted high calibre experimentalists as well as theoreticians. Nor is their importance declining: far from it, as the advent of lasers has provided tools for even more subtle experiments. The diatomic molecule has been the subject of vast numbers of experiments and its importance breaks out from the vicious circle of experiments being done for theoreticians who do calculations to explain experiments. Two-atom molecules are of wider interest, because of their key roles in interstellar molecule formation, atmospheric physics, energy transfer mechanisms and in the development of new laser systems.

The time is clearly ripe for a major

work on all aspects of the physics and chemistry of diatomic molecules. This is not that book, but any such publication might well be dedicated to Robert S. Mulliken.

The actual work under review provides a survey and analysis of computational studies of the electronic structure of ground and excited states of diatomic molecules. It is neither a student text nor a full monograph. It commences with a useful summary of theory which can largely be found in a number of other texts and which is probably too condensed for the novice and too familiar for the expert. Succeeding chapters treat one-electron molecules, two- to four-electron molecules, hydrides and finally homopolar and heteropolar species.

Electron correlation is emphasised as are charge distributions, but the other molecular properties which are the object of *ab initio* calculation are only given a cursory treatment. The bibliography contains some 1976 references but in the text an important 1974 paper is described as 'recent'.

Perhaps the combination of distinguished authors and important topics raises expectations which are bound to be disappointed. The book will be welcomed by the small band of theoreticians who work on diatomic molecules but will probably miss the potentially wider audience. It might just provoke someone to write or edit the major tome on all aspects of diatomics.

Dielectric Behaviour of Biological Molecules in Solution

**E. H. Grant, R. J. Sheppard,
and C. P. South**

Dielectric studies can provide valuable information on the structure and properties of biological molecules and are finding direct applications in medicine as well as in biology. This survey, intended for those who need an introduction to this field of research, covers the role of dielectric studies in biophysics; dielectric theory; the measurement of permittivity; the analysis of experimental results; water and small biological molecules; and proteins and larger structures. £11 *Monographs on Physical Biochemistry*

Nuclear Heavy-Ion Reactions

P. E. Hodgson

The development during the last ten years of heavy-ion accelerators that give nuclei enough energy to interact strongly has revealed a wealth of new phenomena that are being extensively studied. In this book for graduate students our present knowledge of heavy-ion reactions is summarized, together with the theories used to account for them and their application to determine features of nuclear structure. £18 *Oxford Studies in Nuclear Physics*

Blood Groups and Diseases

**A. E. Mourant, Ada C. Kopeć,
and K. Domaniewska-Sobczak**

In this book, the authors bring together the widely scattered data on the frequencies of blood groups and other biochemical characters in persons suffering from each of a wide range of diseases, and analyse them statistically. The research worker is thus provided with a unique key to the literature; the clinician is shown how to apply the results by assessing susceptibility to specific diseases and the prognosis in established disease, and in some cases in planning treatment. £25 *Oxford Monographs on Medical Genetics*

The Genetics of the Jews

**A. E. Mourant, Ada C. Kopeć,
and K. Domaniewska-Sobczak**

In this monograph the authors present much statistical data that could not be included in *The Distribution of the Human Blood Groups* (1976, £55) and they also analyse the available information more fully and relate it to the history of the communities concerned. The extensive work now in progress in Israel and elsewhere on hereditary disease has been taken into account. £12.50 *Research Monographs on Human Population Biology*

Circle No. 09 on Reader Enquiry Card.

obituary

G. W. Kenner, 1922–1978

WITH the tragic death of Professor G. W. Kenner at the early age of 55 we have lost a most distinguished organic chemist, and the leading authority on peptide and protein synthesis.

George Wallace Kenner was born in Sheffield in 1922, of parents who were both chemists; his father, James Kenner, F.R.S., became Professor of Technological Chemistry in Manchester in 1928 and George spent most of his boyhood there attending the Grammar School. Although he was educated and excelled on the classical side at school, the pull of the family profession was obviously strong for he turned to chemistry when he entered University in 1939. First in Manchester and then in Cambridge he displayed prodigious talents for science, still recalled by his contemporaries. Possibly because of the breadth of his education, his early interests in chemistry covered an unusually wide span and continued to do so for the rest of his career.

His first research, in Manchester with Professor (now Lord) Todd, was on nucleotide synthesis and this, together with the synthesis of nucleotide co-enzymes, continued when the group moved to Cambridge in 1944. The structure, chemistry, and total synthesis of biologically important compounds was to remain Kenner's consuming research interest.

In 1957, as possibly the brightest of Todd's galaxy of young Cambridge stars, he came to Liverpool to the Heath Harrison Chair of Organic Chemistry, in succession to a select band of organic chemists: Sir Robert Robinson (1915–20), Sir Ian Heilbron (1920–33), and Alexander Robertson (1933–57). He found a department which, though well-known as a centre for classical natural product research, was rather run down and was very deficient in modern equipment. Sheer ability and enthusiasm gained him the support of the staff and with them he quickly built up an impressively equipped modern department. Almost immediately he started to plan the splendid Robert Robinson Laboratories

Godfrey Argent, Camera Press London

which, occupied in 1961, are still in the forefront of modern chemistry buildings and now provide a permanent monument to his life and work. Working in them nearly twenty years later, one can still sense the explosive energy at the origin of this particular part of the universe.

He showed vision and magnanimity in building up the department, in creating the right atmosphere for good research, and in the staff he appointed. Particularly imaginative was his invitation to Alan Battersby to a new Second Chair of Organic Chemistry in 1962, one of the first such appointments in the country. Their combined talents contributed greatly to organic chemistry and established the department as an international research centre which, in the twenty-one years of Kenner's leadership, expanded beyond recognition.

During this time he also played an important part in undergraduate teaching and in University affairs. While he served skilfully on many major boards and committees, he was not a committee man. He trusted more to the benign dictatorship of departmental

heads and provided a splendid example of that system at its best. He became steadily less tolerant of recent democratic trends in Universities and the associated bureaucracy; his Royal Society Research Professorship, which was the first ever held in Liverpool, brought a welcome relief from many administrative chores.

He was deeply dedicated to his work and expected much of his associates; indeed he was fond of equating academic freedom with the freedom to work still harder! Sadly, the standards he demanded of himself were often unattainable and he sometimes suffered, as perfectionists must. He always said and did exactly what he thought right, regardless of personal considerations and expediency. He was, nevertheless, a splendid colleague, charming and unfailingly courteous, lively and forceful, and there was rarely a dull moment in his company! He had a superb command of English, spoken and written, and his early classical training often erupted with flair, never more pungently than when dealing with sloppiness of thought or action, from whatever source. Even away from the laboratory George did not do things by halves, and he gained immense pleasure from sailing, hill walking, and driving, buying and selling fast motor cars and motor-bikes.

His scientific originality and judgement were widely respected and his services were constantly in demand by industrial, academic and professional organisations. He was a much valued industrial consultant and a champion of genuine collaboration between academic and industrial research, for which he greatly admired the Swiss. His extensive and important scientific work in Liverpool, especially in the fields of porphyrin and protein synthesis, culminated in the present herculean task of total synthesis of a protein closely related to the natural enzyme lysozyme, with the aim of shedding light on the mechanism of lysozyme action. His synthetic techniques and criteria of purity were those of the rigorous organic chemist since

he emphatically rejected the view that standards could be relaxed when the molecules became large and complex. The linear sequence of Liverpool lysozyme's 129 amino acids, fully protected, has been constructed and the final, though demanding, phase of the work is concerned with removal of the protecting groups. Although he will not see the conclusion of this pioneering work, he had already brought new scientific standards to the art of peptide synthesis and provided a firm foundation on which others can, and undoubtedly will, build in the future.

This work had brought him most honours and distinctions available to a British chemist. He was awarded the Meldola and Corday-Morgan Medals, gave the Tilden, Simonsen, and Pedler Lectures of the Chemical Society, and the Bakerian Lecture of the Royal Society. This last, *Towards Synthesis of Proteins* (*Proc. R. Soc. A* 1977, **353**, 441), provides a fascinating account of the strategy and achievements of the lysozyme project.

In spite of the constant demands upon him he always found time to help with the countless problems brought to him. He had an impressive memory for all who passed through the department and he followed their subsequent careers with genuine interest. Recent tragic events have shown just how many people respected and revered him, and are now left, with his wife and daughters, to mourn this splendid man.

C. W. Rees

M. V. Keldysh

MSTISLAV VSEVOLODOVICH KELDYSH, former President of the Academy of Sciences of the USSR, died on 24 June 1978.

Keldysh was born in Riga in 1911. He graduated from the Faculty of Physics and Mathematics in Moscow State University in 1931, and then went to the Zhukovskii Central Aerodynamics Institute, where he worked on mathematical aerodynamics, including the theory of unstable wing movements and flutter.

Although Keldysh was later to be acknowledged as having played a founding role in the establishment of post-war Soviet technology—computer mathematics, nuclear engineering and space research—he remained, to the outside world, relatively unknown, save as a mathematician, until 1961, when he became President of the Soviet Academy of Sciences. Although the Academy still elects its President by

secret ballot, Keldysh's appointment was largely seen abroad as being associated with expansion of the Soviet space programme.

As President of the Academy he played a major role in the expansion of Soviet science, and the development of a Union-wide network of scientific research establishments and centres. His speeches on the progress of Soviet science became a prominent feature of virtually all Party and academic occasions.

Keldysh retired from the Presidency of the Academy in 1974, shortly before the belated celebrations of its 250th anniversary. He still continued, however, to take an active part in the organisation of Soviet science, serving, for example on the Committee for Lenin and State Prizes.

For his services to Soviet science, Keldysh was honoured during his lifetime by the title of Hero of Socialist Labour (three times), Lenin and State prizes and numerous medals and orders of the Soviet Union and the countries of the socialist bloc. As a further and final tribute he was accorded a state funeral, his ashes being enshrined in the Kremlin wall.

Vera Rich

C. O. Hebb

DR CATHERINE OLDING HEBB, formerly Deputy Chief Scientific Officer, A.R.C. Institute of Animal Physiology, Babraham, Cambridge, died at Cambridge on 26 August 1978, aged 67.

Catherine Hebb was born in Nova Scotia and educated at Dalhousie University, Halifax, Nova Scotia, and at McGill University, Montreal. Here in 1937 she gained her Ph.D. and carried out her first research, on the secretory activity of the digestive glands, under Professor B. P. Babkin.

In 1938, Dr Hebb came to Edinburgh University as a Junior Beit Memorial Fellow, in the Department of Physiology, under the late Professor I. de Burgh Daly. For the next fourteen years, in collaboration with Daly and other members of his very active department, Catherine Hebb produced a series of papers on the control of the blood supply to the lungs by neural and chemical processes. During the Second World War, she and Daly undertook research in the department at Edinburgh on behalf of the Air Ministry and the Ministry of Supply. Throughout this period, until 1952, Dr Hebb was giving lectures to undergraduates

in the physiology department, including some to the students of the refugee Polish Medical Faculty in Edinburgh.

When Dr Daly was appointed first Director of the Agricultural Research Council Institute of Animal Physiology at Babraham, Cambridge, he invited Catherine Hebb to join his staff. Dr Hebb's work on the lung vasculature, together with a year's work with Professor W. Feldberg in Cambridge, during the tenure of a Senior Beit Fellowship, led her to an interest in the autonomic system and neurotransmitters, and it was in this field that her most important scientific contribution was made. She established at Babraham a first-rate neurochemical laboratory, and in 1965 became the head of the Institute's physiology department.

Chemical transmission from nerve-ending to effector organ had been familiar to physiologists for decades, but neuron-to-neuron transmission, in ganglia and in the central nervous system itself, was a newer, promising and technically difficult field when Dr Hebb began work in it. Her studies on the mechanism of the synthesis of acetylcholine, and of the distribution of the enzymes concerned in its metabolism, combined the techniques of biochemistry, histochemistry and classical pharmacology. However, among all this fine detail she never lost sight of the physiological functioning of the whole animal, and for this reason among others, she was able to write excellent review articles, putting her own discoveries and those of others in their proper context. The Physiological Society monograph on the vasculature of the lung which she wrote in collaboration with I. de Burgh Daly in 1966 is still a standard work.

Dr Hebb was notable for the sympathetic encouragement which she gave to younger workers in the field of neurochemistry, including a number from Poland, Yugoslavia, Czechoslovakia, Hungary and South American countries. She helped to bring such workers to Babraham for periods of research and study, thereby disseminating enthusiasm for the subject and also a wish to emulate her own high standards of work.

Dr Hebb had already been battling against ill-health for some ten years when she retired from Babraham in 1976. Her concern for others was typified by her request that the collection made to mark her retirement should be used to establish a loan fund to help staff, visiting scientists or students at Babraham in financial need. Contributions to this Catherine Hebb Loan Fund have flowed in from every continent—an indication of the width of the affection for Catherine Hebb and admiration for her work.

announcements

Meetings

7 December, **Strategy for Nutrition Research**, London (Dr M. R. Turner, British Nutrition Foundation, 15 Belgrave Square, London SW1, UK).

9 January 1979, **Annual Histochemistry**, London (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

13-15 March, **Safety of Electrical Instrumentation in Potentially Explosive Atmospheres**, Chislehurst (Mrs R. G. Keilher, Sira Institute Ltd, South Hill, Chislehurst, Kent, UK).

26-30 March, **Quantitative Microscopy (Including Image Analysis)**, Cambridge (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

26-28 March, **Microscopy of Amorphous Solids**, Cambridge (The Administrator, Royal Microscopical Society, 37-38 St Clements, Oxford, UK).

28-30 March, **Mechanical Properties of Materials at High Rates of Strain**, Oxford (Meetings Office, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

2-6 April, **Principles of EM and Specialised Transmission EM**, Leeds (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

9-11 April, **Microscopy of Semiconducting Materials**, Oxford (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

24-27 April, **5th International Conference on Invertebrate Tissue Culture**, Lucerne (E. Kurstak, Département de Microbiologie et Immunologie, Faculté de Médecine, Université de Montréal, C.P. 6128, Succ. A. Montréal, P.Q. Canada H3C 3JL).

29 April-5 May, **15th EUCHEM Conference on Stereochemistry**, Burgensstock (Prof. Sir Derek Barton, FRS, Institut de Chimie des Substances Naturelles, CNRS, F-91190 Gif-sur-Yvette, France).

9 May, **3rd Annual Electron Microscopy Meeting**, Aston (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

6-8 June, **Towards 2001—New Information Technology and Its Future Impact**, Torquay (Mike Allen, Beecham Pharmaceuticals, Coldharbour Rd, The Pinnacles, Harlow, Essex, UK).

2-6 July, **Course on Introduction to Advanced Imaging Techniques for Biologists**, Leeds (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

8-14 July, **International Conference on Climate and History**, Norwich (Conference Secretary, Climatic Research Unit, School of Environmental Sciences, University of East Anglia, Norwich, UK).

9-13 July, **2nd International Conference on the Mechanisms of Reactions in Solution**, Kent (Dr John F. Gibson, The Chemical Society, Burlington House, London W1, UK).

9-13 July, **1st International Botanical Microscopy Meeting**, York (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

10-12 July, **Immunocytochemistry**, York (The Administrator, Royal Microscopical Society, 37/38 St Clements, Oxford, UK).

16-18 July, **Automation in Industrial and Clinical Chemistry**, London (Beverly Humphrey, Scientific Symposia Ltd, 33/35 Bowling Green Lane, London EC1, UK).

16-19 July, **Endocrinology**, London (Conference Secretary, RPMS Du Cane Rd, London W12, UK).

Meetings, Awards, Appointments, On the Move, and Person to Person are listed on the "announcements" pages of *Nature*.

Entries for any of these sections should be sent to: *Nature*, 4 Little Essex St, London WC2, UK. (There is no charge for this service.)

The previous list of meetings was in *Nature* of 12 October, page xvii.

24-27 July, **Video and Data Recording**, Southampton (Conference Secretariat, Institution of Electronic and Radio Engineers, 99 Gower St, London WC1, UK).

30 July-3 August, **7th AIRAPT International High Pressure Conference**, Le Creusot (Andre Kusubov, University of California, Lawrence Livermore Laboratory, California 94550).

13-17 August, **Electron Microscopy Society of America: 37th Annual Meeting**, San Antonio (Dr William H. Massover, Division of Biology and Medicine, Brown University, Providence, Rhode Island 02912).

19-23 August, **3rd International Conference on the Chemistry and Uses of Molybdenum**, Michigan (Climax Molybdenum Co. Ltd, Imperial House, 1/3 Grosvenor Place, London SW1, UK).

20-24 August, **Artificial Intelligence**, Tokyo (Prof. Raj Reddy, Dept of Computer Science, Carnegie-Mellon University, Pittsburgh, Pennsylvania 15213).

20-25 August, **3rd International Conference on Surface and Colloid Science**, Stockholm (The Swedish Institute for Surface Chemistry, c/o Stockholm Convention Bureau, Strådvagen 7C, S-114 56 Stockholm, Sweden).

26-31 August, **4th International Symposium on Environmental Biogeochemistry**, Canberra (The Conference Secretary, Australia Academy of Science, PO Box 783, Canberra City, ACT 2601, Australia).

28 August-1 September, **Neurochemistry of the Retina**, Athens (Dr Nicolás G. Bazán, Instituto de Investigaciones Bioquímicas, Universidad Nacional del Sur-Conicet, Av Alem 1253, 8000-Bahía Blanca, Argentina).

29-31 August, **IUPAC Symposium on Mycotoxins and Phycotoxins**, Lausanne (Prof. P. Krogh, Dept of Veterinary Microbiology, School of Veterinary Medicine, Purdue University, West Lafayette, Indiana 47907).

30-31 August, **Japan Conference on Polymers and Plastics**, Tokyo (Vijay Mohan Bhatnagar, Alena Enterprises of Canada, PO Box 1779, Cornwall, Ontario, Canada K6H 5V7).

Wild M40—the simple, direct way.

Investigations in vitro.

Laboratory vessels, Erlenmeyer flasks, tissue culture chambers and Terasaki chambers are placed directly in the beam path of the Wild M40 inverted microscope. Liquids, sediments, precipitates, solution processes, crystal formation, culture growth and chemical reactions can therefore be readily observed.

The controls are conveniently low slung, and there is a six-place nose-piece. The base, the drive housing and the optics carrier form a single rigid unit which imparts the necessary stability to the instrument. The rich variety of interchangeable accessories enables the instrument to be expanded for cytology, bacteriology, immunology, environmental studies, chemistry etc. The information is in brochure M1 140e.

Microbiological Research Establishment

Enzymes for Clinical Laboratory Use

Broad spectrum beta-lactamase
50 × 1000 units in VIALS @ £75.

A sterile, lyophilised mixture of 4 enzymes which has activity against a wide range of penicillins and cephalosporins, including cefuroxime.

In addition to beta lactamases I and II from *Bacillus cereus*, it contains enzymes derived from *Enterobacter cloacae* and *Escherichia coli*.

It is suitable for inactivating beta lactam antibiotics in samples of blood and other body fluids.

Gentamycin acetyl transferase
50 × 2 milliunits in VIALS @ £100

A lyophilised product derived from a strain of *Escherichia coli*.

It is suitable for determining aminoglycoside antibiotics including amikacin, gentamycin, kanamycin, neomycin and tobramycin in the presence of other antibiotics.

Glycerokinase
5000 units @ £100.

This product is supplied as a suspension in 3.2M ammonium sulphate (1000 units*/ml, 100 units*/mg protein).

It is derived from *Bacillus stearothermophilus* grown at 55° and is very much more thermostable than the enzymes derived from *E. coli* and *C. mycoderma*.

It is suitable for the determination of serum triglycerides.

*Units defined at 30°

3-Hydroxybutyrate dehydrogenase
200 units @ £100

This product is supplied as a suspension in 3.2M ammonium sulphate (16 units/ml, 19 units/mg protein).

It is derived from *Rhodopseudomonas spheroides* and is used for the determination of ketone bodies.

Prices include packing and delivery. UK orders are subject to VAT at ruling rates. Send your order to the Microbial Products Section, Microbiological Research Establishment, Porton, Salisbury SP4 0JG, Wiltshire, UK.

what's new

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. More detailed information may be obtained by circling the appropriate numbers on the Reader Enquiry Card, bound inside the cover.

A feature on biochemicals, enzyme reagents, assay kits and radioimmunoassay will appear in the 14 December issue.

KineticSystems Corporation. KineticSystems announce a new stand-alone microcomputer system for monitoring and control applications as well as countless business and personal uses. The development of this mini CAMAC crate provides proven system performance in a smaller, more economical package. This version of the 8010 Microcomputer System will accommodate a wide variety of needs since it may be programmed in BASIC or assembly language. Because of the modularity of CAMAC, this system is inherently flexible and can be easily configured for nearly any application. The choice of over 1,000 CAMAC modules ensures that each version of an 8010 system provides both an economical solution to process automation and limitless expansion capabilities for future requirements. Communication between the microcomputer and the modular components of the 8010 System is via a microcomputer peripheral bus which supports up to 64 kilobytes of RAM and EPROM memory, diskette drives, and as many as seven crate controllers and their associated crates of process I/O modules. A standard CAMAC crate can contain the 8010 microcomputer system and provide 19 additional stations for monitoring and control modules. The mini CAMAC crate version of the 8010 system offers all the power of the standard configuration in a smaller package containing 12 stations. Two stations are taken by the crate controller, 10 stations are used for I/O modules, and the remaining non-crate area contains two diskette drives with controller, 16 kilobytes of RAM, five kilobytes of EPROM, a microcomputer, and the power supplies. The 8010 System can drive a CAMAC serial highway containing up to 62 remote crates or a CAMAC branch highway containing up to seven crates.

Circle No. 55 on Reader Enquiry Card.

Digital equipment. A mobile, easy-to-use, low-cost laboratory computer system comprising a choice of seven functional modules and based on a PDP-11/03 processor has been announced by Digital Equipment. Known as MINC, the compact cart-mounted computer system includes improved software features that make application development easy even for those who have not used a computer before. The software, MINC BASIC, is an easy-to-learn extension of PDP-11 BASIC. Statistics, numerical analysis, matrix operations and a range of other programs are included in an interactive MINC application package. MINC can also run RT-11 FORTRAN IV for those who wish to process FORTRAN IV programs. All basic MINC configurations include a 32K-word PDP-11/03 with extended and floating point instructions sets, three serial line inputs and an IEEE 488 standard bus interface enabling as many as 14 laboratory instruments and

MINC from Digital Equipment

testing devices to be supported. Also included is a double-density dual diskette unit for program and data storage and a new video graphic terminal, the VT105. The terminal has full alphanumeric capabilities, plus a graphics facility of 512 horizontal by 240 vertical positions. Data can be presented graphically in point or histogram mode, and alphanumerics are presented in upper and lower case, normal, underlined, bold face, and video reverse. Characters can also be presented double-height, double-width, or both.

Circle No. 56 on Reader Enquiry Card.

Bailey. Fast reading surface stainless steel temperature probes provide temperature readings of hard or soft surfaces in 2–5 s. This fast response is due to a reduced thermal time lag which is achieved by a reduced amount of metal in both the thermocouple and probe shaft. A further advantage of the design is improved accuracy of reading due to the elimination of any conductive cooling or heating by the shaft. Model BT-1 contains a type T (copper/constantan) micro-thermocouple; model BK-1 uses a type K (chromel/alumel) micro-thermocouple. The probes can be used with any Bailey digital thermometer or with other thermocouple instruments.

Circle No. 57 on Reader Enquiry Card.

Kevex. Three radioactive isotopes and a low powered X-ray tube are combined for the first time in the new Kevex 7000/9000 X-ray energy spectrometer. A four position X-ray fluorescence turret selects the desired photon excitation source. Monochromatic X-rays are provided in three energy regions by the selected radioisotopes while broad energy range excitation (bremsstrahlung) is supplied by the X-ray tube.

Circle No. 58 on Reader Enquiry Card.

Astro-Med. A new high-speed position feedback galvanometer for direct-writing recorders which doubles the accuracy of conventional galvanometer recorders is now available from Astro-Med. It incorporates the Pathfinder transducer and is easily interchangeable with all existing Astro-Med galvanometers. The new position feedback galvanometer will increase accuracy in a wide range of monitoring applications in the medical, industrial and scientific fields.

Circle No. 59 on Reader Enquiry Card.

Dyonics Inc. The new Flex-a-Lite provides intense cold light illumination for examinations yet keeps microscope stage uncluttered. Flex-a-Lite is a flexible, fibre optic light guide with a pair of arms that provide cross-illumination of the specimen or can light the subject from above and underneath. Featuring an adjustable intensity range, Flex-a-Lite can provide from 125 to 1,000 foot candles of cold light, without affecting delicate specimens. Lenses can be removed to provide broad, soft lighting, and accessories for filtering and light control are available for photographic applications.

APPOINTMENTS VACANT

UNIVERSITY OF OKLAHOMA

CHEMISTRY DEPARTMENT

Applications are invited for a

POSTDOCTORAL RESEARCH ASSOCIATE

The position is in single crystal X-ray diffraction of natural products, siderochromes-iron transport compounds, cyclic peptides and molecules of biological importance. Strong background in diffractometry, computing and structure determination is required. Opportunity to become involved in the biochemistry of siderochromes.

The appointment will be for one to three years and is available immediately. The salary is \$10,000 to \$12,000 per year.

Applications together with curriculum vitae and names of references should be sent as soon as possible to:

University of Oklahoma
Department of Chemistry
620 Parrington Oval
Norman, OK 73019
Attn: Dr D. van der Helm.

The University of Oklahoma is an Equal Opportunity/Affirmative Action Employer. 7989(A)

IMPERIAL COLLEGE RESEARCH ON LASER LIGHT SCATTERING:

1. POSTGRADUATE RESEARCH ASSISTANT to study the detection and monitoring of asbestos fibres in the environment. Three-year project supported by the Health and Safety Executive. Applications are invited from candidates with a good honours degree in an appropriate subject or equivalent. The successful candidate may register for a higher degree. Starting salary in the range £3,384 to £3,883 (under review) plus London weighting and superannuation.

2. POSTDOCTORAL RESEARCH ASSISTANT to study the optical properties of coal particles in flames, under two-year research project sponsored by the Central Electricity Generating Board. Candidates should have a Ph.D. in an appropriate subject, starting salary to £4,133 (under review) plus London weighting and superannuation.

Applications, including curriculum vitae and the names of two referees, should be sent to Dr A. R. Jones, Department of Chemical Engineering and Chemical Technology, Imperial College, Prince Consort Road, London W7 2BY. 8045(A)

BIOCHEMIST—MOLECULAR BIOLOGIST

The Department of Biological Sciences, Carnegie-Mellon University invites applications from molecular biologists whose research interests lie in the area of nucleic acid structure and/or function. Candidates should have postdoctoral experience. The position is at the assistant professor level, although higher appointments will be considered. Duties include teaching at the undergraduate and graduate level as well as maintaining an active research programme. Applicants should forward their curriculum vitae, three or more letters of reference and a brief résumé of research plans to Search Committee (2), Department of Biological Sciences, Carnegie-Mellon University, 4400 Fifth Ave., Pittsburgh, PA 15213. Carnegie-Mellon University is an Equal Opportunity/Affirmative Action Employer. 7349(A)

French Government Scholarships for further study and postgraduate research in France in Pure and Applied Science, Technology, Medicine, Social Sciences, Economics, Geography and Agriculture are offered for the academic year 1979-1980. Candidates, who must be United Kingdom citizens, should be university graduates or have equivalent qualifications. Closing date: December 20, 1978. Details and application forms from Scientific Department, French Embassy, 41 Parkside, Knightsbridge, LONDON SW1X 7JP. Citizens of the Commonwealth and of other countries should apply direct to French Embassies in their respective countries. 7904(A)

UNIVERSITY OF LIVERPOOL CYTOGENETICS UNIT TECHNICIAN/MEDICAL LABORATORY SCIENTIFIC OFFICER

Applications are invited for a post associated with the cytogenetic diagnostic service provided for the Mersey Regional Health Authority.

Work primarily involves tissue culture and microscopy. Experience in human chromosome techniques and/or tissue culture preferred.

Minimum qualification O.N.C. in appropriate subject required. Salary according to qualifications and experience in a range up to £3,060 p.a. and for candidates who are State Registered, up to £4,680 p.a.

Application forms may be obtained from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/966/N. 7998(A)

SCIENTIFIC JOURNALS SUB EDITOR

Owing to the expansion of our periodical department, we have a new post for a trainee sub editor. The job would suit a recently qualified graduate in one of the physical sciences. The successful candidate would initially work on the JOURNAL OF MATERIALS SCIENCE but following training, the job would expand to include work on other journals and on scientific books.

Please apply in writing, with curriculum vitae, to Richard Stileman, Managing Director, Chapman & Hall, 11 New Fetter Lane, London EC4P 4EE.

8067(A)

Division of Hormones POST DOCTORAL SCIENTIST

POST doctoral scientist required to work on a three year project into research on Human Growth Hormone, its characterization and biological activities, using a variety of in vivo and in vitro techniques.

Candidates (male/female) should have a good honours degree and research experience in a biological science.

Appointment is for three years; salary in accordance with age and experience, on University lecturing scales.

Interviews in early November.

Application forms and further details from Personnel Officer, National Institute for Biological Standards and Control, Holly Hill, Hampstead, NW3 6RB. Tel: 01-435-2232 ext 211 quoting reference number 0167.

Pharmacokineticist

May & Baker Ltd., is an international Company, manufacturing and marketing a wide range of research based chemical products.

Following a functional reorganisation, we have a vacancy in the Department of Drug Metabolism at our Research Institute at Dagenham, Essex, for a graduate with pharmacokinetic experience.

The successful applicant will lead a small team working on the design, implementation and competent reporting of pharmacokinetic and bioavailability studies. A good knowledge of analytical apparatus and its application is essential and a general knowledge of drug metabolism is desirable.

Benefits of employment include flexible working hours, bonus scheme and contributory pension scheme. Publication of appropriate work is encouraged and the Department has active links with a number of University and Clinical Pharmacokinetic Departments throughout the world.

Please telephone 01-592 3060 extension 2506 for an application form or write with full details of age, experience, qualifications and present salary to Mrs. Phyllis Clark, Personnel Officer (Scientific Staff),

M&B May & Baker

May & Baker Ltd.,
Dagenham, Essex RM10 7XS
quoting reference number 164/N/I 7999(A)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

Applications are invited for the post of:

RESEARCH OFFICER

in the College's Department of Agriculture. Applicants should have a degree in either:

- (1) Computer Science, preferably with a sound knowledge of, and postgraduate experience in, agriculture and/or animal genetics; or
- (2) Agriculture or Applied Genetics, with a postgraduate qualification in computer programming.

The successful applicant will be required primarily to organise, develop and analyse a computerised data base on the performance and potential of the Cambridge Sheep breed.

The appointment will be for 2 years in the first instance, and will be to the Universities' Research and Analogous IA Scale:- £3,883 to £6,555 per annum.

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained.

Closing date for applications: October 31, 1978. 8028(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF ORGANIC CHEMISTRY

Applications are invited for two temporary fixed-term posts of POSTDOCTORAL RESEARCH FELLOW. One post will be concerned with the chemistry of trimethylene methane (with Dr R. J. Bushby) and the other post will be for work on the partial synthesis of fluorinated analogues of gibberellin precursors and the study of the effect of these analogues on the biosynthesis of the gibberellins (with Dr B. E. Cross). Both posts are available for a fixed period of one year.

Salary in the range £3,883 to £4,382 of the IA Scale for Research and Analogous Staff (£3,883 to £6,555) (under review).

Applications, giving details of qualifications, research experience and the names and addresses of two referees, should be sent to the Department of Organic Chemistry, The University of Leeds, Leeds LS2 9JT, as soon as possible. 7993(A)

LINCOLN COLLEGE New Zealand

CHAIR IN ENTOMOLOGY (Agricultural Zoology)

The Council of Lincoln College, University College of Agriculture, invites applications for the Chair in Entomology, resulting from the impending retirement of Professor R. A. Harrison.

Applicants should hold an advanced degree in Science or Agricultural Science and have an established record of research and/or teaching in some branch of agricultural zoology.

The successful applicant will be appointed as Head of Department and will be responsible to the College Principal for the administration of his Department.

The appointment will be made within the existing range of professorial salaries, NZ\$23,012 to NZ\$29,188 per annum, the commencing salary being determined by the College Council.

Expenses of appointment reimbursed up to specified limits. New Zealand Government Superannuation is available.

Further details and general Conditions of Appointment are obtainable from the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on January 15, 1979. 8041(A)

COMMONWEALTH AGRICULTURAL BUREAUX

VACANCY FOR SECRETARY TO EXECUTIVE COUNCIL

at

Farnham House, Farnham Royal, Slough SL2 3BN

Duties—The Secretary will be responsible to the Executive Director for the secretarial, administrative, personnel and accounting functions.

Qualifications—Graduate candidates not over 50 will be preferred. Experience in accountancy and administration at a senior level is essential, and a knowledge of law and practices affecting employment would be an advantage.

Salary in the scale £7,825 to £8,729 with provision for superannuation. Initial salary according to age, qualifications and experience.

Applications—Full particulars may be obtained from the Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN. Completed forms should be returned to the Executive Director not later than November 30, 1978. 7996(A)

RESEARCH TECHNICIAN GRADE 3

required to assist with project investigating rabbit red blood cell development, with particular reference to M.R.N.A. and protein synthesis. Knowledge of protein fractionation, chromatography, centrifugation and radioactive techniques is desirable. Minimum qualifications O.N.C./H.N.C. or equivalent, with at least 3 years relevant experience. The post is financed by the M.R.C. for 3 years in the first instance. Salary on scale £3,153 p.a. rising to £3,525 p.a. inclusive (under review). Four weeks annual holiday. College contributory pension scheme. Apply in writing with full details to: The Head Clerk Ref. 204019/N, King's College London, Strand WC2R 2LS. 8042(A)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

Faculty of Science

DEPARTMENT OF BOTANY

SENIOR LECTURER IN GENETICS

Applicants for this position must have broad interests in and knowledge of genetics, substantial experience in University teaching, and a record of productive research. Appointment as Senior Lecturer is for three years in the first instance with possibility of reappointment, after review, to retiring age.

Salary on appointment will be in accordance with qualifications and experience within the range \$A20,365 to \$23,737 per annum. Current exchange rates \$A1 = \$US1.15; £0.58p.

CLOSING DATE: December 2, 1978

Other conditions: Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. 8040(A)

UNIVERSITY OF SURREY

DEPARTMENT OF BIOCHEMISTRY

RESEARCH OFFICER— CANCER RESEARCH

Applications are invited for the post of Research Officer to undertake research into factors affecting the development of lung cancer. Preference will be given to applicants with experience in at least one of the following areas: Biochemistry of nucleic acids, tumour promoters and handling of animals. The work is supported by the Medical Research Council and the position is tenable for two years. Salary: £3,384 to £3,883.

Applications, in the form of a curriculum vitae, and the names and addresses of two referees should be sent to the Staff Officer, University of Surrey, Guildford, Surrey GU2 5XH by November 10, 1978.

Further particulars may be obtained from Dr G. M. Cohen, Department of Biochemistry, University of Surrey, or telephone Guildford 71281, ext. 821. 8006(A)

UNIVERSITY OF SOUTHAMPTON

FACULTY OF MATHEMATICAL STUDIES CHAIR OF OPERATIONAL RESEARCH

Applications are invited for the Chair of Operational Research. Salary within the professorial range. Applicants should have an established reputation in the field of Operational Research. Further particulars may be obtained from the Secretary and Registrar, The University, Southampton SO9 5NH, and applications (11 copies from applicants in the United Kingdom) must be submitted before November 28, 1978. Research in Forensic Science

Development of analytical techniques, instrumentation and data handling

The Central Research Establishment of the Home Office at Aldermaston, is actively engaging in the overall research effort and co-ordination of the work within the Forensic Science Service, while also acting as an information centre for the Service as a whole. The Establishment, equipped with the most modern and sophisticated techniques to analyse and examine a wide range of materials, currently has a number of challenging career opportunities for Research Scientists within four operational Divisions:

BIOLOGY

Opportunities for Biochemists and Serologists to research new methods of grouping human tissues, including saliva, semen and hair. There is a particular need for a Serologist with wide experience of hospital pathology laboratory or blood transfusion work, and for a Biochemist with knowledge of protein fractionation techniques (eg electrophoresis).

TOXICOLOGY

Analytical Chemists and Biochemists are needed to research new methods of identification and quantification for drugs and metabolites in body tissues

and fluids using HPLC, GLC, MS and RIA techniques. Experience in the fields of pharmacokinetics and drug metabolism would be an advantage.

CHEMISTRY

Chemists and Physicists are required for general trace analysis of materials of all kinds using XRF, IPC-Arc, Pyrolysis Mass Spectrometry, AAS, UV/IR Spectrophotometry together with computerised data storage, etc.

INFORMATION

This division needs Information Scientists, Chemists and Biologists for the development of data acquisition, storage and dissemination procedures for use on the Division's own computer and terminal facilities with on-line links to the Regional Forensic Science Laboratories, also for operating Quality Assurance and External Contract procedures and for answering urgent requests for information from the regional laboratories.

INFORMATION (COMPUTER SECTION)

A further vacancy exists for a Computer Scientist to work on the day-to-day operations of a 16K Hewlett-Packard

21000A computer and associated peripheral equipment, also involving maintenance of the equipment and programming of new applications in forensic science. A knowledge of small computer systems and Fortran is essential.

The above opportunities are available at Scientific Officer, Higher Scientific Officer and Senior Scientific Officer levels for which a relevant honours degree is preferable. Salary levels according to age and experience: SO (£2,840-£4,410); HSO (£4,100-£5,450) at least 2 years postgraduate experience required; SSO (£5,150-£6,900) at least 4 years postgraduate experience. Good promotion prospects. Non-contributory pension scheme.

For an application form (to be returned by 10 November, 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: SB/20/LA.

TECHNICIAN CELL BIOLOGY

Division of Viral Products requires a suitably qualified laboratory technician to work in the field of cell biology.

Preference will be given to candidates (male/female) with experience in tissue culture techniques of mammalian cells and/or biochemical techniques applied to virology.

Salary—dependent on age, qualifications and experience on scale £3,815 to £5,034 p.a.

Applications and further details from Personnel Officer, NIBSC, Holly Hill, Hampstead, NW3 6RB Tel: 01-435 2232 ext 211 quoting reference number 0170.

NIBSC

National Institute for Biological Standards and Control
9016(A)

HEAD OF PHARMACOLOGY DEPARTMENT

A leading Spanish Pharmaceutical Company situated in the mediterranean city of Barcelona invites applications from pharmacologists for the above post in a Pharmacology Department. The man we appoint will have a good honours degree in an appropriate discipline, a Ph.D. in pharmacology and several years postdoctoral experience preferably in the pharmaceutical industry.

The successful applicant will be responsible to the director of Biological Sciences and must be able to formulate and organise research and development projects and collaborate with the other departments in the Biological and Chemical science groups.

Knowledge of Spanish is not initially essential but the successful candidate must be prepared to acquire adequate fluency in this language within 2 years. The salary is tax free and negotiable at around 30,000 dollars p.a. and special assistance will be given for removal expenses to Barcelona.

Applications in writing with full curriculum vitae should be addressed to:

Pharmacology Department
P.O.B. 1583
BARCELONA-24 (Spain) 7986(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the temporary post of

DEMONSTRATOR

In the above Department from suitably qualified candidates. The person appointed will participate in teaching biochemistry to science and to medical students and will also be expected to carry out research on the molecular biology of bacterial drug resistance in collaboration with Dr J. H. Parish. The post is tenable from January 1, 1979 until September 30, 1979. Salary at an appropriate point on the IB Scale for Other Related Staff (£3,384 to £5,604) (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University of Leeds, Leeds LS2 9JT, quoting reference number 83/16/D. Closing date for applications November 6, 1978 8002(A)

UNIVERSITY OF SALFORD

DEPARTMENT OF BIOLOGY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a Postdoctoral Research Fellow sponsored by the Science Research Council, to investigate the respiratory physiology of birds during exercise (non-flying) and vocalisation under the supervision of Dr J. H. Brackenbury. Experience in respiratory/blood gas analysis an advantage. The appointment is tenable for three years commencing as soon as possible.

Commencing salary within the range £3,883 to £4,328 per annum. Application forms obtainable from the Registrar, University of Salford, Salford M5 4WT (tel: 061-736 5843, ext. 215) to whom completed applications should be returned not later than Friday, November 17, 1978, quoting reference number B/83/N 8064(A)

THE ROYAL VETERINARY COLLEGE

University of London
Division of Preclinical Studies
DEPARTMENT OF
PHYSIOLOGY
LECTURER IN
PHARMACOLOGY

Applications are invited from veterinary, medical and science graduates, including recent veterinary graduates who wish to make a career in Veterinary Pharmacology. The main teaching responsibility is Veterinary Pharmacology for the BVetMed degree and it is also closely linked with the teaching of therapeutics. The appointee will also be expected to assist with the Honours B.Sc. course, to pursue research and to advance knowledge of the scientific basis of veterinary therapeutics.

Prospective applicants are encouraged to get in touch with either the Head of Department, Professor M. G. M. Jukes, or Dr P. Lees, Reader in Veterinary Pharmacology.

SALARY SCALE (under review). £4,333 to £5,204 including London Allowance. Initial salary determined by experience and qualifications. Superannuation under the Universities' scheme.

The post is available from a date to be arranged.

Removal expenses up to £800 may be reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU (telephone 01-357 2896).

CLOSING DATE FOR APPLICATIONS: November 10, 1978 7948(A)

QUEEN MARY COLLEGE

University of London

Applications are invited for the post of MOLECULAR GENETICIST to undertake research on the genetic manipulation of yeast with special reference to transformation studies. Applicants should have research experience in Microbial Genetics and/or Molecular Biology.

The appointment is sponsored by a major industrial organisation and the selected candidate will be on the payroll of the Company concerned. Following a 2-3 year period of research at Queen Mary College, the successful candidate will be transferred to the Company's own research laboratories.

A competitive salary and non-contributory pension rights in accordance with the Company's own scale will be offered to the successful candidate. Further details will be given at interview.

Applications should be made by October 27 to: Professor E. A. Bevan (N), Professor of Genetics, Queen Mary College, Mile End Road, London E1 4NS. 8039(A)

THE OPEN UNIVERSITY LECTURERS IN BIOLOGY

We have two vacancies: those appointed will be involved in the preparation and maintenance of the discipline's 2nd and 3rd level courses in one or more of the areas of Ecology, Mammalian Physiology, and Molecular Biology/Biochemistry. They will also be expected to take an active interest in the development of the discipline's future offerings in the field of continuing education, and to undertake research—either independently, or with one of the existing research groups. Successful candidates should have a good research record and teaching experience.

Applications for the posts should be able to demonstrate an ability to write clearly and easily and an interest in distance teaching. Both posts are tenured. Salary will be on the scale £3,883-£7,764 (under review) and there are USS and other benefits.

Application forms and further particulars are available, by postcard request please, from the Recruitment Office (JD3682/4), The Open University, PO Box 75, Walton Hall, Milton Keynes, MK7 6AL, or telephone Milton Keynes 63868. 24 hour answering service.

Closing date for applications: 3rd November, 1978 8064(A)

QUEEN CHARLOTTE'S MATERNITY HOSPITAL

Goldhawk Road, London W6

BASIC GRADE or SCIENTIFIC OFFICER (Cytogenetics)

Applications are invited from science graduates with honours degrees for the above posts. Preference will be given to candidates with experience in diagnostic work in human cytogenetics. Whitley Council terms and conditions of service. The diagnostic laboratory which is fully equipped, may be visited by appointment. Interested applicants are advised to contact Dr D. Huxley (Tel: 01-748 4666, Ext. 223) in the first instance.

Application forms obtainable from and returnable to The Administrative Assistant (Ext: 204) 8014(A)

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHYSICS RESEARCH ASSOCIATE

Applications are invited for a postdoctoral Research Associate to undertake a study of liquid semiconductor alloys using photoelectron spectroscopy. The project is part of a wide investigation of the properties of disordered systems being carried out by the Physics Department and supported by the Science Research Council.

The post is tenable for up to 2 years and the salary is from £3,883 p.a.

Applications with a curriculum vitae and the names of two referees should be sent to Dr C. Norris, Department of Physics, University of Leicester, LE1 7RH. 8049(A)

THE OPEN UNIVERSITY

Faculty of Science Research Assistant

Applications are invited for a post of Research Assistant in the Science Faculty. The post is funded by a research grant and is available for two years.

An analysis of the educational effectiveness of the Open University Science Foundation Course has been undertaken to enable an improved version of the Course to be made and presented to students in 1979. Information will be collected on the educational effectiveness of the new Course and the Research Assistant will be required to assist in the collection and analysis of this material.

Candidates should have a first degree in a scientific subject and an interest in educational technology is essential. Familiarity with Open University courses, particularly S100 would be an advantage.

Application forms and further particulars are available by postcard request please from The Recruitment Office (JD2891/4), The Open University, P.O. Box 76, Walton Hall, Milton Keynes, MK7 6AL, or telephone Milton Keynes 63404: there is a 24 hour answering service on 63868.

Closing date for applications: 3rd November 1978. 8043(A)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF PHYSICS

Applications are invited from men and women for a RESEARCH POST in the field of MAGNETOSPHERIC PHYSICS, financed by the S.R.C. and tenable for three years. The person appointed will assist in the analysis of V.L.F. wave data from the GEOS 1 and 2 satellites as part of a collaborative European programme. Candidates should have postgraduate experience in an appropriate field and computing experience is highly desirable. Salary on Range 1A up to £4,382 per annum. Particulars from the Registrar and Secretary, the University, Sheffield S10 2TN, to whom applications should be sent together with the names of two referees as soon as possible. Quote ref: R 207/G. 8001(A)

UNIVERSITY COLLEGE HOSPITAL

DEPARTMENT OF MEDICAL PHYSICS PHYSICIST/ELECTRONICS ENGINEER

(Basic Grade Physicist Scale)
MEDICAL LABORATORY
SCIENTIFIC OFFICER

Two vacancies exist in a team involved in the development and evaluation of blood gas analysis sensors. The Physicist/Electronics Engineer will be expected to collaborate on the design and building of instrumentation associated with the sensors. The M.L.S.O. will be involved in the laboratory testing of the sensors together with animal and clinical trials.

Both appointments are for one year in the first instance.

Applications with the names of two referees should be submitted to, Mr D. Delpy, Dept. of Medical Physics, U.C.H., Shropshire House, Cannon Street, London W.C.1. Tel. 387 9300 Ext. 119. 8038(A)

The Department of Zoology of the University of California, Davis announces the vacancy of an ASSISTANT PROFESSORSHIP in the area of Developmental Biology

The Department of Zoology invites applications from persons with primary interests and experience in research and teaching in any area of developmental biology. The appointee is expected to establish a productive research program and to participate in the department's program of graduate instruction. Teaching responsibilities include a one-quarter introductory course in embryology, a one-quarter advanced course in developmental biology, and participation in a graduate seminar in developmental biology. Candidates must have a Ph.D. degree. Salary will depend upon qualifications and experience.

Applicants should forward a curriculum vitae, a description of their research experience and future research plans, reprints of all publications, a summary of teaching capabilities, and three letters of recommendation to Dr R. D. Grey, Chairperson of the Search Committee, Department of Zoology, University of California, Davis, CA 95616. The University of California is an equal opportunity/affirmative action employer. Closing date for receipt of applications is November 30, 1978. 7975(A)

SCHERING erwartet Sie

Für unser Department Entzündungspharmakologie, mit den Arbeitsgruppen Dermatologie, Rheumatologie, Allergologie, suchen wir einen

Mediziner oder Biologen

mit mehrjähriger experimenteller Erfahrung. Unser neuer Mitarbeiter soll die Arbeitsgruppe Rheumatologie leiten. Er wird an der Wirkstofffindung teilnehmen und das Gebiet in seinem vorklinisch experimentellen Teil im Hause und extern vertreten. Der Schwerpunkt seiner wissenschaftlichen Arbeiten wird auf dem Gebiet der Immunologie und Molekularbiologie liegen.

Wenn Sie dieses Arbeitsgebiet interessiert würden wir uns freuen, mit Ihnen Kontakt aufnehmen zu können und mit Ihnen zu diskutieren. Bitte, schicken Sie uns Ihre Bewerbungsunterlagen oder rufen Sie uns an (Tel. 030/468 2853 oder 468 2922).

TELEPHONE: 01 831-6901

UNIVERSITY OF BASEL FACULTY OF SCIENCE

In connection with the reorganisation of the Department of Zoology applications are invited for the following positions:

PROFESSOR from October 1, 1979

ASSOCIATE PROFESSOR from
November 1, 1979

A further Professor is expected to be appointed at a later date.

Experience is desired in one of the following fields: Sensory physiology, ecological ethology, morphology including electron microscopy.

Duties include general teaching in zoology and collaboration in research and teaching with special emphasis on ecological aspects.

Applications stating publications, teaching experience, curriculum vitae etc. should be submitted until the end of December 1978.

Address: Dekanat der Philosophisch-Naturwissenschaftlichen Fakultät der Universität Basel, Klingelbergstrasse 70,
CH-4056 BASEL / Switzerland.
7992(A)

ANATOMIST

Applications are invited for a vacant position in Anatomy at the assistant or associate professor level. Applicants should possess an M.D. and/or Ph.D., and have experience in teaching gross anatomy to medical students. Experience in teaching embryology or histology would be an asset.

Candidates would be expected to have a strong research background. Excellent facilities are available in histology, neuroscience, molecular biology, immunology and cell physiology.

Salary will be commensurate with experience.

Applicants should send a curriculum vitae and names of three referees to Dr T. M. Scott, Chairman Anatomy Search Committee, Faculty of Medicine, Health Sciences Center, Memorial University, St. John's, Newfoundland, Canada A1B 3V6.

8047(A)

ROYAL MARSDEN HOSPITAL

Downs Road, Sutton, Surrey
MEDICAL LABORATORY
SCIENTIFIC OFFICER—
CLINICAL PATHOLOGY

Required for Clinical Chemistry section of Clinical Pathology Department. Experience and/or interest in protein analysis would be useful.

Application forms from Personnel Department R.M.H. London tel: 352 1171 Ext. 447.

Closing date: October 31, 1978.

8011(A)

UNIVERSITY OF EXETER DEPARTMENT OF BIOLOGICAL SCIENCES RESEARCH TECHNICIAN

required to assist in a project supported by the S.R.C., to investigate the mechanism of cytoplasmic transport in cells. Previous experience in biochemical techniques and microscopy would be an advantage.

The appointment will be for two years, starting as soon as possible, with a salary £2,688 to £3,060 per annum (Grade III). Minimum qualifications: O.N.C. Science and preferably three years' experience.

Applications giving full details and naming two referees should be sent to Dr H. Stebbings, Washington-Singer Laboratories, Perry Road, Exeter EX4 4QG, to reach him not later than November 3, 1978.

8035(A)

QUEEN'S UNIVERSITY, Kingston, Canada. Plant Scientist. Research and teaching position for a scientist with an established research program, preferably in the area of plant physiology. Rank and salary are negotiable but are expected to be in the middle range. Those interested should send a detailed resume together with the names of three referees to H. M. Good, Chairman Selection Committee, Department of Biology, Queen's University, Kingston, Ontario, Canada.
7984(A)

AGRICULTURAL COLLEGE OF ATHENS

1. The Agricultural College of Athens, Greece, a University level Institution, has a vacancy for the Chair in

FLORICULTURE AND LANDSCAPE ARCHITECTURE

This position will be officially advertised within 1978 and it is open for qualified candidates who have Greek citizenship with a Ph.D. or equivalent recognised degree in Ornamental and/or Environmental Horticulture. Interested specialists should submit as soon as possible a letter with a biographical sketch to the Dean, Professor D. Papamichael, Agricultural College of Athens, Botanikos, Athens 301, Greece. Details for application will be forwarded upon request.

2. The Agricultural College of Athens, Greece, a University level Institution, has a vacancy for the Chair in

VEGETABLE CROPS

This position will be officially advertised within 1978 and it is open for qualified candidates who have Greek citizenship with a Ph.D. or equivalent recognised degree in Vegetable Crops. Interested specialists should submit as soon as possible a letter with a biographical sketch to the Dean, Professor D. Papamichael, Agricultural College of Athens, Botanikos, Athens 301, Greece. Details for application will be forwarded upon request.

7985(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the post of **SENIOR LECTURER IN THE DEPARTMENT OF ANIMAL PHYSIOLOGY**. Applicants must have Ph.D. in mammalian physiology, preferably in ruminant gastroenterology, neurophysiology or cardiovascular physiology. They must have considerable teaching experience at University level. Applications should be accompanied by six reprints of the candidate's most important papers as evidence of ability to organise and carry out meaningful and original research. Salary Scale: K£2,988 to K£3,984 p.a. (K£1-£1.35 Sterling). The British Government may supplement salary by £4,770 p.a. (Sterling) for married appointee or £3,252 p.a. (Sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; S.S.S.F. or F.S.S.U.; subsidised housing/housing allowance; non-contributory medical aid scheme. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar, Recruitment and Training, University of Nairobi, P.O. Box 30197, Nairobi, Kenya by November 20, 1978. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

8037(A)

BIOCHEMIST, Probationary Grade, Whitley A Scales, required for the routine department of Chemical Pathology, 17 Page Street, London SW1P 2AR. Possibility of London M.Sc. course to follow, with excellent training rotation. Applicants with 1st or 2nd Class Honours should write to Professor J. R. Hobbs at the above Department, with the names of two referees, by October 30, 1978.

8027(A)

UNIVERSITY COLLEGE OF NORTH WALES/GWYNEDD HEALTH AUTHORITY SENIOR RESEARCH OFFICER IN ULTRASOUND

Applications are invited for this new joint appointment which provides a challenging opportunity to develop a research programme in ultrasound at the College, and to give scientific support to an evolving clinical ultrasound service for North Wales.

Applicants should have a good Honours degree or similar qualification, proven research ability and relevant experience. The appointment will be to the Universities' Research and Analogous grades 1A/II, £3,883 to £7,754 per annum.

Applications (two copies), together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd, LL57 2DG, from whom further particulars may be obtained.

Closing date for applications: October 31, 1978. 7974(A)

ASSOCIATE RESEARCH POSITION

Applications are invited from post-doctoral fellows with the experience and the background involved in the isolation and cloning of gene sequences. Salary commensurate with experience. Knowledge of German is not required.

Forward letter of application giving full details and the names and addresses of two referees to:

Dr A. Ruiz-Carrillo, Max-Planck-Institut für Molekulare Genetik 1000 Berlin 33, Ihnestrasse 63-73, BRD.
7979(A)

VICTORIAN COLLEGE OF PHARMACY LTD Parkville, Victoria, Australia DEAN SCHOOL OF PHARMACEUTICAL CHEMISTRY

(Salary Aust.\$31,789 p.a.)

(£518,536 at September 26, 1978 ex. rate)

Applications are invited for the above position which will become vacant on January 1, 1979 when the present holder, Dr G. N. Vaughan takes up the position of Dean of the College.

The College is divided into three semi-autonomous Schools: Pharmaceutical Chemistry, Pharmacology and Pharmaceutical Chemistry. The present Deans of Schools are Professor I. H. Pitman (Pharmaceutics) and Professor C. Raper (Pharmacology).

A full description of the College, the School of Pharmaceutical Chemistry and the specifications for the position are available from Mr R. Burnet, Registrar, Victorian College of Pharmacy Ltd., 381 Royal Parade, Parkville, Victoria, Australia, 3052. (telephone (03) 380 6254).

Preference will be given to applicants of proven strength in Medicinal Chemistry, but any person who has had experience in pharmacy and pharmaceutical education in any area related to analytical chemistry, physical chemistry, biological chemistry, etc., could be considered as suitable applicants. The position commands full professional status.

Applications close December 31, 1978.

Small Animals Centre

MICROBIOLOGIST

We are expanding our microbiological facilities and wish to appoint microbiologist or bacteriologist to supervise the running of a laboratory which services internal research projects and provides a routine service to veterinary surgeons in practice. Current topics of research interest include scarlet diseases of infectious origin, especially infectious bovine keratoconjunctivitis, canine renal disease and the fading puppy complex. Applicants should possess a good honours degree in a relevant discipline. Veterinary surgeons are welcome to apply and would be expected to specialise in one of the above fields. The successful applicant would be encouraged to register for a higher degree. Salary commensurate with University Scales.

The laboratories are modern, well equipped and situated four miles from Newmarket in pleasant parkland. Further details of the appointment can be obtained from the Director, Animal Health Trust, Small Animals Centre, Lanwades Park, Kennett, Nr. Newmarket, Suffolk CB8 7PN.

7981(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post-doctoral post of Senior Research Assistant to work on a project funded by a Cancer Research Campaign grant to Dr A. G. McLennan on the use of viruses as probes for error-prone DNA repair in human fibroblasts. Experience of tissue culture and nucleic acid techniques desirable. The appointment is for one year in the first instance and may be renewed for a further two years. Initial salary within the range £3,384 to £4,382 per annum.

Applications together with the names of two referees, should be received not later than November 3, 1978, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/965/N.

UNIVERSITY OF GLASGOW

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Post-doctoral Research Assistant supported by the M.R.C. to work with Dr B. E. H. Maden on the fine structure of the ribosomal genes in vertebrates. The work will involve recombinant DNA technology and is part of a group project aimed at the molecular characterisation of RNA processing events during ribosome maturation. The appointment will commence as soon as possible and will continue until September 14, 1981, subject to satisfactory progress.

The salary will commence within the range £3,883 to £5,129 on Range 1A of the salary scale for Research and Analogous Staff, the starting point to be determined by the successful candidate's age, qualifications and experience.

Applications, including curriculum vitae and the names of two referees, should be sent to Dr B. E. H. Maden, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ. In reply please quote Ref. No. 1261M.

8052(A)

KENYATTA UNIVERSITY COLLEGE—KENYA

(a constituent college of the University of Nairobi)

Applications are invited for the following posts in the DEPARTMENT OF GEOGRAPHY:—

ASSOCIATE PROFESSOR. Candidates should hold a Ph.D. in Geography and considerable teaching experience at University level, preferably at Senior Lecturer level. They should also provide evidence of successful research activity through publications in respectable geographical and allied journals. The appointee will be expected to have experience in training of secondary school teachers and to be capable of providing academic and administrative leadership in the department.

SENIOR LECTURER. Applicants should hold a Ph.D. in Geography plus substantial teaching and research experience at University level. All fields of specialisation will be considered but possession of special qualifications in Human Geography will be advantageous.

Salary scales: Associate Professor K£3,864 to K£4,488 per annum, Senior Lecturer K£2,988 to K£3,984 per annum (K£1 equals £1.34 sterling). The British Government may supplement salaries in range £4,770 to £5,052 per annum (sterling) for married appointees and £3,252 to £3,438 per annum (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; subsidized housing; S.S.S.F. or F.S.S.U.; non-contributory medical aid scheme. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent direct to the Registrar, Kenyatta University College, P.O. Box 48344, Nairobi, Kenya by November 16, 1978. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

■ Make field surveys and visit farmers to determine the extent and methods of use of pesticides ■ Process data by computer.

□ Degree, HNC or equivalent in agricultural, horticultural or biological subject □ Experience in computing advantageous □ Possession of current driving licence essential □ Age normally under 27 □ Appointment as Scientific Officer (£2840-£4410) □ Ref: SB/18/AG.

■ Application forms (to be returned by 13 November 1978) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke (0256) 68551 (answering service if office closed).

Safety in the Food & Cosmetic Industries

Information Scientist

... to work on problems associated with the safety in use of cosmetics, food-contact materials and medical devices. The work includes scanning literature for relevant articles for reference files, carrying out literature surveys on various chemicals associated with cosmetics and food-contact materials, preparing reports and papers for consideration by expert advisory committees, collating and evaluating data, and consulting with representatives of the cosmetic and food industries.

Candidates, normally aged under 30, should have a degree or equivalent qualification in a relevant discipline and several years postgraduate experience. A knowledge of toxicology would be an advantage.

Appointment as Higher Scientific Officer (£4560-£5910). Starting salary according to qualifications and experience. Non-contributory pension scheme. Promotion prospects.

For further details and an application form (to be returned by 9 November 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: SB/3/KE.

THE UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF
CHEMISTRY

Applications are invited from candidates with teaching and research interest in any aspect of IN-ORGANIC CHEMISTRY including BIOLOGICAL INORGANIC CHEMISTRY for an appointment at the Assistant Professorship level.

Applications consisting of a curriculum vitae, a list of publications and the names and addresses of three referees should be sent to the undersigned before December 31, 1978. This post is open to both male and female applicants.

Professor Charles A. McDowell
Department of Chemistry
University of British Columbia
2075 Wesbrook Mall
Vancouver, British Columbia
Canada V6T 1W5

8032(A)

THE ROWETT RESEARCH INSTITUTE

Buckburn, Aberdeen, AB2 9SB

BIOCHEMIST

SCIENTIFIC OFFICER/HIGHER SCIENTIFIC OFFICER

A Biochemist is required to investigate the relationship between cell wall structure and digestibility of forages. This post is in the Carbohydrate Biochemistry Department (Head: Dr J. S. D. Bacon), which has as its main interest the digestion of polysaccharides by ruminants. Members of the Department have wide experience in the determination of polysaccharide structure and in the purification and characterisation of enzymes attacking the glycosidic bond, and the Department is well equipped in these respects.

The successful candidate will work on the chemical characterisation of the factors that limit the digestion of the cell walls of forages by the microbial flora of the rumen, entailing studies on the preparation of cell walls, their composition, the kinetics of their degradation and the morphological changes associated with the microbiological processes.

The results are expected to throw light on the structural features of the plant cell wall that affect its digestibility and also upon the chemical treatments that may increase it.

Qualifications: First or upper second class Honours Degree in Biochemistry, and an interest in Agriculture and Animal Nutrition.

Salary Scales: Scientific Officer £3,294 to £4,415 per annum or Higher Scientific Officer £4,101 to £5,448. Starting salary and grade will be dependent on experience. At least two years' relevant post graduate experience is required for consideration for appointment in the HSO grade.

There is a non-contributory Superannuation Scheme.

Applications, together with a curriculum vitae and the names and addresses of two referees should be sent to the Secretary of the Institute, from whom further particulars can be obtained.

Closing date November 10, 1978

8026(A)

THE ROYAL
VETERINARY COLLEGE

University of London

Division of Paraclinical Studies

DEPARTMENT OF PATHOLOGY

LECTURER IN

VETERINARY PATHOLOGY

Applications are invited from veterinary graduates for the post of Lecturer in Veterinary Pathology. Duties will include participation in teaching the undergraduate and post-graduate courses in pathology and some diagnostic work. The successful applicant will be encouraged to take advantage of the good research opportunities which are available.

Preference will be given to applicants having some relevant experience in postmortem diagnosis, histopathology or similar fields, but consideration will be given to applications from recent graduates or others.

SALARY SCALE (UNDER REVIEW). £4,333 to £8,204 inclusive of London Allowance. Initial salary will be determined according to qualifications and experience. Superannuation under the Universities' scheme.

Removal expenses up to £800 may be reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. Telephone: 01-357 2898.

CLOSING DATE FOR APPLICATIONS: November 6, 1978. 7964(A)

Freshwater

Biological Association

RESEARCH ASSISTANT

Vacancy for Assistant Scientific Officer (ASO)—Scientific Officer (SO) to assist in work on the physiological ecology of planktonic algae and environmental factors of lakes, involving experimental and field studies. Two places at 'A' level (or equivalent) specialising in science, or a degree in biology, ecology, or environmental sciences.

Salary: ASO £2,188 (age 18), £2,665 (age 21) to £3,303 (max.); SO £2,839 to £4,415 (max.).

Further details and application form from: Secretary, Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0EP. Telephone Windermere (096 62) 2468. Closing date: November 10, 1978. 7968(A)

OVERSEAS DEVELOPMENT

KNOW-HOW vital to developing countries

A 3-MAN TEAM consisting of:

- (i) TROPICAL AGRONOMIST
- (ii) SOIL PHYSICIST
- (iii) CROP PHYSIOLOGIST Botswana

is required for a Dryland Farming Research scheme—Phase III, situated at the Agricultural Research Station, Gaborone. The team will study edaphic and aerial factors affecting establishment of optimal stands of Sorghum and Maize for maximum yield over cycles of wet and dry seasons within the context of a new and modified farming system. The research is closely associated with projects evaluating the results under farmers' conditions and establishing a pilot scheme for their adoption. Applicants aged 30-55 years should be a graduate in science, agricultural or soil science with preferably previous overseas research experience.

Appointment 3 years. Salary in range £5,700 to £9,700 p.a. plus tax-free overseas allowance in range £1,360 to £3,375. (Ref. 331.)

These posts are wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, childrens' education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply quoting reference stating post concerned, and giving details of age, qualifications and experience to:

RESEARCH INSTITUTE
Buckburn, Aberdeen AB2 9SB
APPLIED NUTRITION
DEPARTMENT

Applications are invited to fill a vacancy in the Institute's Applied Nutrition Department. The successful candidate will work on the effects of nutrition and of management on reproduction in the sow, and particularly on ways in which the frequency of breeding can be increased. The work would entail studies of the artificial rearing of baby pigs.

Candidates should have a first or upper second class honours degree in the biological sciences or agriculture or equivalent qualification.

The appointment will be as a

SCIENTIFIC OFFICER

(£3,294 to £4,415 p.a.)

or a

HIGHER

SCIENTIFIC OFFICER

(£4,101 to £5,448 p.a.)

grade and starting salary depends on experience. At least two years' relevant postgraduate experience is required for H.S.O. grading.

There is a non-contributory pension scheme.

Further details of the post may be obtained from the Secretary of the Institute, to whom applications should be submitted together with the names of two people to whom reference can be made. Closing date, November 3, 1978. 8068(A)

ELSEVIER INVITES
APPLICATIONS FOR AN
ACQUISITION EDITOR
IN AMSTERDAM

Elsevier Scientific Publishing Company, Amsterdam, The Netherlands, invites applications for the position of Acquisition Editor in the department of Engineering and Technology. After a training period, the successful candidate will, together with his/her colleagues in the department, further develop the Elsevier publication programmes in this field.

Candidates are expected to hold a university degree in an appropriate subject, which could be civil, chemical, mechanical, electrical engineering, or geology or materials science. Experience as an acquisition editor in these fields would be an advantage but is not essential. He or she should be able to communicate clearly and easily, be willing to move to Amsterdam, be under 35, and be keen to work outside a narrow specialisation.

Applications with full curriculum vitae, passport photograph, and an indication of present and expected salary should be sent to the Head, Personnel Department, Elsevier Scientific Publishing Company, P.O. Box 2400, Amsterdam, The Netherlands 7976(A)

PRE AND POSTDOCTORAL

of Newfoundland. 8003(A)

Accelerator Physicists for SNS Rutherford Laboratory

The Rutherford Laboratory of the Science Research Council has recently undertaken to design and construct a major new experimental facility known as the Spallation Neutron Source (SNS). This will consist of a fast cycling 800 MeV proton synchrotron delivering 2.5×10^{13} protons per pulse at 50Hz onto a heavy target to produce an intense source of neutrons. When completed the SNS will be a world class facility serving a wide community of research workers in the study of condensed matter by neutron scattering techniques.

The Laboratory is now seeking a number of young physicists to join the design team on this advanced and challenging project. Vacancies are available in a number of areas of the work which includes such topics as accelerator machine theory, magnet design, vacuum technology, high power rf systems, electronics, control systems and target design.

Suitable candidates will have graduated within the last few years and will be qualified either to carry out original design and development work, or to provide experimental or theoretical support within a project group.

Appointment will be at either the Scientific Officer or the Higher Scientific Officer level, depending on age and experience. Salary will be in the range:

Scientific Officer — £3037 - £4724

Higher Scientific Officer — £4388 - £5829

There is a contributory pension scheme, generous leave and sick leave allowances.

The Rutherford Laboratory is situated on the Berkshire Downs, about 18 miles south of Oxford. It has its own restaurant and recreational facilities. Shops, banking facilities, hostels and further sports and recreational clubs are available on the adjoining AERE Harwell site. Daily travel is available from most of the neighbouring towns and villages direct to the Laboratory.

Application forms are available from:

RUTH JEANS of the Personnel Group.

UNIVERSITY OF BRISTOL
DEPARTMENT OF PHYSICS
TECHNICIAN GRADE 5

Applications are invited for the above post involving operation and maintenance of a Cambridge S4 Scanning Electron Microscope with associated optical, electronic and photographic equipment used chiefly in cathodoluminescence experiments. Other duties include operation and maintenance of X-ray apparatus and of equipment for cutting and polishing crystals. Plenty of scope exists for initiative in assisting with new developments. Previous experience in above-mentioned specialised work not essential, but experience in general laboratory practice including vacuum technique and some electronics is desirable.

Salary within the range £3,186 to £3,720 per annum (scale under review), and the position is funded for two years.

Applications, stating age, experience and qualifications should be sent as soon as possible to Dr A. R. Lang, H. H. Wills Physics Laboratory, Tyndall Avenue, Bristol BS8 1TL. 8073(A)

MISCELLANEOUS

IF YOU HAVE developed audio-visual program(s) in science on the college level or higher, Science-Thru-Media Co. is interested in possibly manufacturing and marketing your program both nationally and internationally. You will get a royalty on the gross sales. Write or call Terry Hillman, Science-Thru-Media Co., 295 Fifth Avenue, Rm. 819, New York, NY 10016, (212) 684-5366 7924(J)

UNIVERSITY OF EDINBURGH

TAIT CHAIR OF MATHEMATICAL PHYSICS

Applications are invited for the Tait Chair of Mathematical Physics which will fall vacant on the retirement of Professor N. Kemmer, F.R.S. on September 30, 1979. Applications from theorists in any branch of Physics will be considered.

Salary within the professional range, with U.S.S./F.S.S.U.

Further particulars may be obtained from

The Secretary to the University
University of Edinburgh
Old College
South Bridge
Edinburgh EH9 9YL

with whom applications (12 copies), giving the names of three referees, should be lodged by December 15 if possible. (Overseas candidates need submit only one copy of their application.) Please quote reference 13/78. 8013(A)

RHODES UNIVERSITY GRAHAMSTOWN SOUTH AFRICA

Applications are invited for the post of

PROFESSOR OF ENTOMOLOGY

with effect from January 1, 1979 or as soon as possible thereafter.

The initial salary will be determined according to qualifications and experience within the salary scale R10,800 by R450 to R12,600 by R600 to R13,800 per annum. In addition a supplement of 15% per cent on the above scale and a vacation savings bonus are payable. (Note: £1 sterling equals approximately R1.73). The successful applicant will become a member of the University's pension and medical aid schemes.

Preference will be given to candidates with teaching and research interests in the field of insect ecology or physiology.

Further particulars and application forms may be obtained from the Registrar (Personnel Section), Rhodes University, Grahamstown, South Africa, to whom completed applications together with a recent photograph should be sent by November 4, 1978. 7978(A)

AWARDS

AUSTRALIAN INSTITUTE OF MARINE SCIENCE Postdoctoral Awards

The Australian Institute of Marine Science is a Statutory Authority established in 1972. Its functions are to carry out research in marine science, to assist other persons and institutions engaged in research in this field and to disseminate information relating to marine science.

The Institute is located in modern facilities at Cape Ferguson 60 kilometers from Townsville.

A number of Postdoctoral Awards are granted each year by the Council of the Institute for research by young scientists of exceptional promise and proven capacity for original work in the area of marine science.

The awards are tenable at the Institute for periods up to two years. Tenure of an award is expected to commence within nine months of the award being made.

In general, awards are restricted to applicants who are not more than 30 years of age on the date when applications close. Applications may also be considered from candidates for the Ph.D. degree if a thesis has been submitted for examination.

Stipend

\$10,059 to \$14,064 per annum.

Allowance

A district allowance of \$340 per annum for married awardees and \$180 for single awardees is payable.

Applications

Persons interested in applying for an award should submit an application and the names and addresses of three professional referees to the Secretary, Australian Institute of Marine Science, P.M.B. No. 3, M.S.O. Townsville, Queensland 4810, Australia.

Each application should be accompanied by a curriculum vitae and should detail a research proposal with scientific justification, procedures and objectives. Details of necessary laboratory and/or field support should be documented.

Applications should be submitted before the 15 December, 1978. 8068(A)

FELLOWSHIPS

UNIVERSITY OF STRATHCLYDE

Applications are invited from graduates in engineering, physics or other relevant disciplines for

TWO RESEARCH FELLOWSHIPS

In the BIOENGINEERING UNIT to work in the Unit's programme of investigation of biomechanics of human movement. Preference will be given to candidates with a research degree and with experience in the measurement of human biomechanics.

One Research Fellowship, financed by the Scottish Home and Health Department, is involved with the investigation of the reproducibility of prosthetic limb alignment and the changes in structural loading produced by controlled alterations in alignment.

The other Research Fellowship, financed by the Medical Research Council, is concerned with the investigation of the loading of both hips and both knee joints during normal activity for patients with joint disease at one or more of these sites. Patients will be tested before and at intervals after joint replacement.

Both posts are for a period of three years and are on Range 1A of the national salary structure for research and analogous staff. The S.H.H.D. Fellowship will be on the scale £4,382 by £249 to £4,631 by £251 to £4,882 and the M.R.C. Fellowship on the scale £4,631 by £251 to £4,882 by £247 to £5,129. Placing on respective scales according to qualifications and experience. Superannuation benefit.

Written applications with the names and addresses of two referees (quoting R38/78) should be forwarded to Professor J. P. Paul, Bioengineering Unit, Wolfson Centre, University of Strathclyde, 106 Rottenrow, Glasgow G4 0NW (Tel. 041-552-4400, ext. 3030), from whom further details can be obtained. Please state in which post interested. 8029(E)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF IMMUNOLOGY

Applications are invited for the post of postdoctoral research fellow in the Department of Immunology to work with Dr P. M. Johnson on the interaction of immunological responses to oncofetal antigens with tumour promotion or inhibition in syngeneic experimental animal systems. Previous experience in cell biology or tumour immunology would be advantageous. Initial salary will be in the range £3,883 to £4,631 per annum.

Applications together with the names of two referees should be received not later than November 3, 1978, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further details may be obtained. Quote Ref: RV/961/N 8008(E)

AGRICULTURAL RESEARCH COUNCIL ANIMAL BREEDING RESEARCH ORGANISATION

Applications are invited for a vacancy in the Department of Growth and Efficiency for work on the genetics of growth and productive efficiency of livestock.

Candidates should have a first or upper second class Honours Degree or the equivalent in an appropriate subject and at least two years' post-qualifying experience in mathematics, statistics, genetics or animal science. They should have the ability to conduct and direct large-scale experiments on cattle fed a controlled complete diet. An ability to analyse data and use extensive computing facilities is essential.

Appointment as Higher Scientific Officer (£4,101 to £5,448), starting salary depending on experience. Non-contributory superannuation.

Further information and application forms are available from the Secretary, ARC Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ. Closing date November 11, 1978. 8012(A)

For those who are seeking a change in their careers we now offer this new service...

FELLOWSHIPS

UNIVERSITY COLLEGE CORK
FISH PATHOLOGY
 Post-Doctoral Fellowship

The National Board for Science and Technology has provided a grant for a study of kidney diseases of cultured salmon and trout.

The appointment will be for one year in the first instance renewable for a further two years.

STARTING SALARY: £3,762 per annum.

Applications with curriculum vitae and the names of two referees should be sent to:

M. F. Mulcahy, Ph.D.,
 Department of Zoology,
 University College, Cork
 (Ireland)

CLOSING DATE: Friday, 3 November, 1978

8010(E)

GIRTON COLLEGE
 CAMBRIDGE

Applications are invited for a scientific research fellowship open to graduates of any university and tenable for three years from October 1, 1979. The applications should be in the field of Mathematics, Natural Sciences, Geography and allied subjects.

The fellowship is to the value of £2,475 per annum to a candidate with a Ph.D. and £2,255 per annum to a candidate who has not completed a Ph.D. The fellowship is pensionable under U.S.S.

Particulars are available from the Secretary to the Council, Girton College, Cambridge CB3 0JG to whom applications should be sent by November 15, 1978. 7913(E)

UNIVERSITY OF
 BIRMINGHAM
 DEPARTMENT OF
 MICROBIOLOGY
RESEARCH FELLOWSHIP

A postdoctoral research fellow required for studies on the pathogenicity of influenza virus supported by the Medical Research Council. Virological training preferred but not essential. The post is for a Research Fellow 1A in the range £3,883 to £6,555, (plus superannuation), beginning January 1, 1979 for two years and nine months. Maximum starting salary will be £4,862.

Applications should be sent to the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, by Friday, November 3, 1978, and further details can be obtained from Professor H. Smith. Please quote ref: NM3. 8004(E)

**POSTDOCTORAL
 RESEARCH
 FELLOWSHIPS IN
 BIOCHEMISTRY**

Applications are invited for two, two-year postdoctoral research positions in the Division of Molecular and Cellular Biology at the National Jewish Hospital and Research Center. The positions involve the study of an *in vitro* RNA processing system (see *Proc. Nat. Acad. Sci. USA* 75, p. 3045, 1978) and the structure and function of ribosomal RNA (see *Biochemistry* 16, p. 5321, 1977). Experience with nucleic acid chemistry and/or the analysis of complex enzyme kinetics is desirable. The beginning salaries are \$11,000 U.S. per year, with some allowance for experience and dependents. Application, with curriculum vitae and names of three referees, should be sent to Dr Norman Pace, N.J.H.R.C., 3800 E. Colfax Avenue, Denver, Colorado 80206 U.S.A. An Affirmative Action/Equal Opportunity Employer 8000(E)

CONFERENCES

CONFERENCE

Third International Conference
 on the Chemistry and
 Uses of Molybdenum

sponsored by the University of Michigan and Climax Molybdenum Co. Ann Arbor, Michigan, U.S.A., August 19-23, 1979.

Application forms can be obtained from:
 Climax Molybdenum Co Ltd,
 Imperial House,
 1/3 Grosvenor Place,
 London SW1X 7DL. 8034(C)

ANNOUNCEMENTS

The Royal Zoological Society of N.S.W. announces publication of the proceedings of a symposium on **MONOTREME BIOLOGY** held in May 1978. The paperback volume contains both review and research papers on topics of monotreme biology ranging from the fossil record to molecular physiology. Cost is \$3.00 (AUST) payable to The Royal Zoological Society of N.S.W., P.O. Box 20, Mosman N.S.W. 2088, AUSTRALIA 7980(G)

POSITIONS WANTED

AGRONOMIST (B.A., M.A.) (Cantab.)
SPECIALIST RESEARCH/ADVISORY AGRONOMIST IN TEA seeks appointment with any Research or Advisory Organisation, or Tea Company on Consultancy or Short Term Contract Basis. In my 50's and offer over 22 years' Research and Advisory experience in Ceylon, East and West Africa, Madagascar and Morocco. BILINGUAL, Fluent French. Also 24 years SUGAR CANE Research, NATAL. 7977(B)

STUDENTSHIPS

UNIVERSITY OF
 LIVERPOOL
 S.R.C. C.A.S.E.
**STUDENTSHIP IN
 MATERIALS SCIENCE**

Applications are invited for a studentship on a project concerned with the structure of non-metallic materials injected with light gas ions. The research will be undertaken in collaboration with the Culham Laboratory, who will make a payment to the student in addition to the S.R.C. studentship. The normal S.R.C. requirements will apply. Applications should be submitted as soon as possible to The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref. RV/959/N. 8007(F)

ASSISTANTSHIPS

UNIVERSITY OF BRISTOL
 Applications are invited for a
POSTDOCTORAL

RESEARCH ASSISTANTSHIP in the Department of Zoology, work on the mechanics of flight, birds and bats, using wake sampling techniques. Candidates may be formally qualified either in zoology, or aeronautical engineering or a related field. They must be able to work with tame animals, have some practical knowledge of electronics and photography, and be proficient at computer programming.

Starting salary up to £4,382 p.a. (scale under review).

Further details from Dr C. J. Pennicock, Department of Zoology, University of Bristol, Woodland Road, Bristol BS8 1UG. 7983(F)

**POSITION IN
 INVERTEBRATE ZOOLOGY
 DEPARTMENT OF
 ZOOLOGY
 UNIVERSITY OF
 CALIFORNIA, BERKELEY**

The Department of Zoology, University of California, Berkeley, anticipates making an appointment at the assistant professor level beginning Fall, 1979 pending final budgetary approval. I successful applicant will be expected to participate in teaching a two quarter upper division course in invertebrate zoology and to offer an advanced course in his/her specialty. Preference will be given to individuals with teaching and research specialization in invertebrate morphology, physiology, endocrinology (excluding neurophysiology and behaviour). Applicants should send a curriculum vitae, copy of publications, a detailed statement of teaching and research objectives and names and addresses of at least three references to: Chairman, Invertebrate Zoology Search Committee, Department of Zoology, University of California, Berkeley, CA., 94720. Applications should be received January 1, 1979.

The University of California is an Affirmative Action Employer. 8015(P)

SYMPOSIA

**SIXTH SUMMER PROGRAM
 in
 METHODS OF
 IMMUNOLOGIC RESEARCH
 AND DIAGNOSIS**

The sixth biennial program on current methods of immunologic research and diagnosis will be offered by The Center for Immunology of State University of New York at Buffalo, June 4-22, 1979. It will consist primarily of a combination of lecture and elective practical laboratory courses to allow the participant to become acquainted with the techniques by personally carrying them out, the bench complemented by demonstrations, lectures and discussions. The entire program is designed to provide the participant with a survey of presently available methodology and insight into the underlying immunologic principles.

Further information may be obtained from James F. Mohn, M.D., Director, The Center for Immunology, State University of New York at Buffalo, 210 Sherman Hall, Buffalo, New York 14214. The deadline for applications is March 31, 1979. 8031(M)

UNIVERSITY OF DUBLIN
 Trinity College

**POSTDOCTORAL
 FELLOWSHIP/RESEARCH
 ASSISTANTSHIP**
 Department of Biochemistry
 Trinity College,
 Dublin 2.

A Position is available for a Postdoctoral Fellowship/Research Assistantship to participate in a Research Project designed to affinity-label and purify the substrate-binding components of a neutral amino acid transport system from plasma membranes of a protozoan.

The position is funded by the Medical Research Council (Ireland) and is for three years at a starting salary of £2,433 (Tax Free).

Candidates will possess an honours degree in Biochemistry or Chemistry and have interests in protein chemistry and cell biology. Enquiries or applications with a brief curriculum vitae to Dr H. P. Voorhees, Department of Biochemistry, Trinity College, Dublin. 8009(E)

The Second Translation Kit

From the people who brought you new convenience and reproducibility with the first.

The First Translation Kit

It will make your life easier and your results more reproducible

New England Nuclear offers the first reticulocyte lysate kit for use in studying protein synthesis. Not only does it save all of the trouble of preparing your own cell extract, it gives you a system free from endogenous mRNA, high in protein synthesis activity, with an optimized high activity tracer and quality control that includes testing every vial of Methionine, L-[³⁵S], using the kit.

The optimal reticulocyte lysate system is reported to contain all factors required for translation of any eukaryotic mRNA. But to use assume the availability of suitable animals, transportation of the lysate, contact and incubation of endogenous mRNA. And the individual taking of the salts, energizer, and amino acid mix.

And you can get rid of all those rabbits

In short, it's a nuisance.

Now add yours.

Call us toll-free for details.

Call us toll-free for details.

Our first translation kit saved you the difficulty of preparing your own lysate for cell-free translation studies, gave you a system free of endogenous mRNA and high in protein synthesis activity, and assured you of components tested for compatibility and reproducible results. All told, it was an excellent excuse to stop cultivating rabbits.

Our second kit does all of the above, too. But, instead of Methionine, L-[³⁵S], the tracer is Leucine, L-[3,4,5-³H]—specially optimized for use with this system. Here's what our Leucine Translation Kit contains:

Rabbit reticulocyte lysate Treated with micrococcal nuclease to inactivate endogenous mRNA and tested to guarantee high protein synthesis activity.

High activity ³H tracer NET-460T, Leucine, L-[3,4,5-³H], >110Ci/mmol. Special lots are prepared and tested for incorporation into protein using this cell-free translation system.

Translation cocktail All the necessary components for proper translation conditions, including buffer, biogenic polyamine, and energizer.

Control mRNA Purified mRNA to check the biological activity of the system.

Salts and sterile deionized water Selected and prepared to minimize potential ionic or enzymatic inhibition of the system.

Instructions for use The protocol is straightforward and includes suggested assay procedures.

So now there are two, and only two, translation kits. Call us toll-free for details on either or both.

The big liberator is here!

A revolution in tissue culture techniques
by Boehringer Mannheim!

The neutral protease "Dispase" is the most favourable enzyme in tissue culture techniques for the enzymatic disintegration of tissues into single cells or to keep cells in suspension culture.

The advantages over trypsin are:

- | | |
|---|--|
| * no damage of cell membranes | * increase of the yield of living cells |
| * no inhibition of cell growth | * no loss in enzyme activity under tissue culture conditions |
| * tissue disintegration in presence of a complete nutrient medium even with serum | * no contamination by viruses or mycoplasmas possible |

Commercially available: Dispase, Grade I, Cat. No. 241 750
Dispase, Grade II, Cat. No. 165 859
Dispase/Collagenase mixture, Cat. No. 269 638

Tomorrow's results today

Get gel filtration results faster with Sephacryl® S-200 Superfine. It has speed and resolution to spare.

- **Cut separation times.** Typical flow rates are 30 cm/hour or better in standard laboratory columns.
- **Cut column packing times.** Sephacryl is pre-swollen ready-to-use in packs of 750 ml and packs fast.

Sephacryl S-200 Superfine is the new gel filtration medium for proteins, polysaccharides and other biopolymers. It combines excellent chemical and physical rigidity with an exclusion limit of $\sim 250,000$ daltons for globular proteins. Sephacryl can be used in detergents, structure-breaking media and organic solvents. It can be autoclaved repeatedly at 120°C .

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976)

26 October 1978

Is proliferation unstoppable?

IN a mere eighteen months' time the Non-Proliferation Treaty (NPT) will come up for its second review conference. The treaty, which came into force in 1970, is intended to prevent non-nuclear-weapon states building their own nuclear devices or receiving them from any other source; in return nuclear-weapon states promise not to transfer nuclear explosives, nor to help others build their own. A majority of all nations adhere to the treaty, but there are a number of potentially nuclear countries who have kept out. West Germany, Japan, Sweden and Switzerland are in, but Argentina, Brazil, France, India, Israel, Pakistan, People's Republic of China and South Africa are not. This latter group contains, of course, three nuclear states, two of which are widely regarded as virtually nuclear and others which could harbour nuclear-weapons ambitions. So the NPT could hardly be said to be an unqualified success.

The first review of the treaty came up in 1975 and was not a happy occasion. The superpowers wanted to emerge unscathed from the conference and were largely successful. The price for this, however, was growing dissatisfaction amongst non-nuclear-weapons states, notably Mexico and Yugoslavia, at the way their self-denial had met with no real promises of restraint on vertical proliferation. In the event no-one withdrew from the treaty, but on the other hand no outsider proceeded to sign.

The 1980 conference could be much more of a cross-roads. Certainly the superpowers will bring a new Strategic Arms Limitation Treaty, and, most likely, a short-duration Comprehensive Test Ban as evidence of self-restraint, though both of these will be heavily criticised. But the real issues will probably be elsewhere. In the past few years, security of future energy supply has tended to supplant other world concerns, including nuclear proliferation. So uranium enrichment, reprocessing and breeder reactors are likely to be topics of importance at the 1980 conference, and the central debate could well focus on the right of nations to have access to these facilities. The Stockholm International Peace Research Institute, SIPRI, has recently held a conference to look at the control of fissionable materials in non-military applications, with a view to stimulating thought on these matters during the run-up to 1980. There are clearly many areas of great concern. Traditional methods of uranium enrichment could be challenged soon by jet-nozzle and vortex-tube techniques in West Germany and South Africa, as well as by laser separation methods. Reprocessing facilities capable of supplying plutonium are being developed in several countries with an eye on export and with the apparent justification of the Non-Proliferation Treaty itself, whose Article IV urges states to cooperate in the further development of peaceful uses of nuclear energy. The technological momentum of breeder research and development is making that device look like the logical next step for some nations, and it has the appeal of enormous savings on resources. Enrichment, reprocessing and breeding all look attractive in the absolute, but all open new doors to the more widespread circulation of weapons-grade materials.

What, the SIPRI meeting asked, is to be set against these proliferative trends? The answer seems to be that no one measure, whether technological, political or institutional

can in itself stem the tide for long; the best that can be hoped for is that by applying as many restraints as possible and in as many ways as possible, non-nuclear countries considering the acquisition of nuclear weapons delay long enough for new attitudes to have emerged, both towards proliferation and towards the role of nuclear energy in national energy strategies. Amongst subjects discussed were the possibility of the International Nuclear Fuel Cycle Evaluation (INFCE) coming up with something valuable; the chances that an Advanced Converter Reactor development in the United States would lead to efficiencies which made a breeder reactor seem unnecessary, at least for the present, possible use of denatured fuel; moratoria on various enrichment technologies and problems posed by fusion-fission hybrids, particularly using inertial confinement techniques. And yet the question ultimately is not technological but political and institutional. Energy independence has become a target, and with many years of almost unbridled enthusiasm for the atom not only in national but also international agencies there is much to be done before new attitudes emerge.

The most overtly political and apparently progressive move so far—President Carter's 1978 Non-Proliferation Act—has not been well-received everywhere. The Act puts strong controls on trading of nuclear materials and equipment originating in the United States, but in exchange tries to assure adequate safeguarded supplies to those countries which co-operate and which have ratified the NPT. Carter has also, of course, been running down domestic development of reprocessing plants and plutonium breeders. Some nations well along the nuclear road have felt this legislation to be discriminatory and unreasonable, even to the extent of wondering whether the United States, whose breeder development was in any case lagging, was not adopting a pious stance based simply on commercial opportunism. In truth Carter's proliferation concern runs much deeper than that, but the last year has shown how unfortunate it is that commercial and national interests are so deeply woven into a fabric already criss-crossed with technological and international problems.

An idea put forward at the SIPRI meeting by A. R. W. Wilson, of Australia, could provide a way out of this bind. He proposes a nuclear fuel supply co-operative of states dedicated to meeting each others' fuel and service requirements whilst minimising the risk of proliferation. Each member would undertake to agree safeguards with the International Atomic Energy Agency (IAEA) and to restrict its access to enrichment and reprocessing facilities, whether on its own or another country's territory, simply to that amount of fuel deemed necessary by the IAEA for the country's power programme. Internationally controlled facilities would not be excluded from the co-operative's activities. The emphasis in the co-operative would be on mutual benefit rather than on surrender of national sovereignty.

This deserves extensive discussion. Much of the criticism of current non-proliferation measures is their sharply discriminatory character; Dr Wilson's proposal would represent a move towards benefit-sharing and should be widely attractive. □

The new exhibition schemes at the British Museum (Natural History) and the consequent changes in the more traditional exhibits have caused some consternation amongst interested scientists. At the recent symposium on Vertebrate Palaeontology and Comparative Anatomy held at Reading, Dr R. S. Miles, Head of the Public Services Department of the Museum explained the Museum's present policy towards its public exhibitions, and we present a summary of his talk below. Dr B. Halstead of the Department of Geology, University of Reading presents an opposing view (right).

A new exhibition on ecology (see above) opens this week . . .

The public's right to know

THE policy of the Public Services Department about what we do in the galleries is not the whim of any one person in the Natural History Museum. It originates with the 1753 Act of Parliament for the purchase of the Hans Sloane Collection. The British Museum Bill says: "The said Museum or Collection may be preserved and maintained, not only for the Inspection and Entertainment of the learned and the curious, but for the general Use and Benefit of the public." The Bill, in other words, distinguished between research and public functions for the museum.

What do we know about the visitors that come? The 'most common' age groups are children below 11 years of age; 26% are adults between 25 and 34 years of age. Of particular interest is the fact that children between 11 and 16 form only 3% of our visitors and young adults between 17 and 20 form only 11%. There is therefore some justification for regarding the Natural History Museum as a 'kids' museum, for children under 11. It appears that people come as young children, only to return when they are parents with their own children. So the vital years in education between 11 and 20 provide less than a quarter of our audience.

Approximately two-thirds of our visitors have completed their full-time education but eight out of ten have no qualifications in biology. Half of all visitors are visiting the museum for the first time and eight out of ten have not visited the museum on a previous occasion within the past year.

But in a summary of results in 1977 from our Annual Visitor Survey we found that many people set out to visit the museum with the expectation of learning something; when they left they had learnt practically nothing, or, more to the point, they gave no evidence of having learned anything, and not one that we interviewed had been stimulated to search out information for him or herself.

I think we are entitled to draw a few tentative conclusions from this. There is little evidence that we are fulfilling the Advisory Board for the Research Council's stated aim for the museum of attracting youngsters to science; and there is little sign of the university student who is supposed to make so much use of the public galleries in the museum. There would seem to be a distinct need for a new approach if we are going to fulfil the terms of the 1753 Bill.

A paper submitted to Trustees for their consideration in February 1972 initiated the new exhibition scheme. Entitled 'A Proposal for a New Approach to the Visiting Public', it starts by discussing the existing exhibition: "it is piecemeal and conceptually static, neglectful of natural processes and reflects to its loss the division of the museum into five separate departments." The 1972 paper says that the new

exhibition should deal with all forms of life, with the origin of the Earth and its life, and with the major geological processes which have affected life. It should point out areas of doubt and speculation and should complement the other national museums in London. It would have a uniquely comprehensive opportunity to display the full range of natural history. The paper suggests that the content of the new exhibition should be grouped under four headings: man, ecology, life processes and behaviour, and evolution and diversity.

There is no intention of reducing the number of organisms on display. On the contrary, the policy is to expand the exhibits illustrating diversity especially in invertebrates and plants which will be dealt with properly for the first time in the history of the museum.

My department of public services was created in January 1975 specifically to implement this new exhibition scheme. We want to make the museum an exciting place where the layman can enjoy exploring and discovering natural history. We need to attract an audience that is representative of the general public. We must recognise the need to motivate visitors.

Departmental policy gives rise to a long-term plan, which was represented by four documents written by museum scientists, members of all the departments. About 40 were involved in all and the four documents cover the four themes. The first three documents have been in the library of the museum since November 1972, the fourth, on evolution and diversity, since October 1973, and open for people to read and send in their comments. The evolution and diversity document, for example, says: "... the aim of the new exhibits on these topics should demonstrate the varied form and structure of species now existing; the historical relationships between them, and their status in the latest stage of continuing process of change on the surface of the Earth." These exhibits will contain the vast majority of the material now on show in the museum. The public will expect us to continue to provide what they have always found to be the most entertaining aspect of the museum—halls of monsters. On a more profound level, we hope the visitor will be able to derive an intellectually satisfying explanation of his origins, his unity with terrestrial life, and his uniqueness and his role. The exhibits will include Recent and fossil species and will be ordered systematically by relationships.

There is a problem to be solved: the diffusion of knowledge to the general public. It is not easily solved, but by a process of trial and error it is possible to develop better solutions. Our whole approach to the operation of mounting the exhibits is based on this assumption. □

... but should the museum stick to scholarly displays?

Whither the Natural History Museum?

IN his account of the thinking behind the new exhibition schemes, Dr Miles has posed clearly for the first time a fundamental dichotomy that exists in the concept of the role of the museum. The Department of Public Services has taken an unequivocal stand that its duty is primarily to serve the general public, and more than that, not to provide mere displays of the materials housed, but to communicate ideas and concepts.

The fundamental issue was summarised succinctly at the meeting by Professor T. S. Westoll. If one sees the role of the museum as one of social engineering, then one follows one route, by implication that of Miles' current policies. But if one sees it as a unique place in which to collect together in a systematic way what is contained in the natural world then clearly the national collection as a repository, with public galleries exhibiting those materials, will develop in a very different manner. It was evident that Miles' conception took no account of the needs of students but was aimed primarily at young people with no knowledge of biology and he saw his main task as one in which he would motivate them to learn. As a body, an audience of both professional and amateur palaeontologists, zoologists and geologists was in the main unsympathetic to Miles' thesis.

By far the most disturbing aspect of the discussion which followed Miles's talk was the strong impression of a serious breakdown of communication between the Museum's Department of Public Services and the scientific staff of the Natural History Museum, such that one of the world's leading ichthyologists on the museum staff was provoked to protest publicly at the recent removal of the fish exhibits to make way for the Human Biology Exhibition. It is known that the Museum's dinosaur expert would much have preferred a completely modernised Dinosaur Gallery, emphasising the natural history of these extraordinary creatures, rather than the entirely new exhibit, largely concerned with reptile relationships, which is now being constructed in the Central Hall. The museum has announced its forthcoming publication on the new dinosaur exhibit and yet its own expert is not involved in its production. This in spite of the fact that as well as being acknowledged as a world expert, he is one of the most experienced people around at communicating his subject to young people and the general public.

Dr H. W. Ball, the Museum's Keeper of Palaeontology, has publicly stressed on numerous occasions that the museum has the responsibility to curate, conserve and display the material objects in its charge.

It has always been assumed by people outside the museum, it now transpires mistakenly, that the public galleries reflected the responsibilities of the museum's

scientific staff working in conjunction with the exhibition staff. The fact that the new exhibition scheme seems to be going ahead in spite of serious opposition from the scientific side of the museum is surely a matter of deep concern.

The rigid dichotomy posed by Miles between the needs of the general public on the one hand and university students and teachers on the other is assuredly false. The late lamented dinosaur gallery was a case in point. It served the needs of the general public but also those of students. A still extant example of the same thing is the fossil mammal gallery. This scholarly exhibition is filled with genuine specimens with explanatory diagrams and models accompanying them. The essence of visiting this gallery is that one can see for oneself the actual evidence on which models and restorations have been based. Visitors have the possibility of deriving their own concepts, drawing their own conclusions. This exhibit can be visited at different stages in life, from a small child, to the general adult public and to advanced students. At each level something of real value can be gained.

Once it is conceded that it is an appropriate role for a national museum to be concerned with aspects of social engineering by promoting concepts that happen to be current in the present climate of opinion, then a most dangerous precedent is set, which has sinister implications. Suddenly it becomes possible to visualise museums contributing to the indoctrination of the more inarticulate sections of the community. Just so long as natural history museums are primarily concerned with displaying the materials in their charge, there is always the possibility that the facts will shine through the prevailing dogmas.

The new scheme as epitomised in the Hall of Human Biology leads to the grave suspicion that henceforth natural history specimens will become simply three dimensional illustrations of a given narrative aimed solely at "an audience that is representative of the general public". In my opinion the museum should be nearer to scientific literature than to the media.

The Natural History Museum's new exhibition scheme raises such fundamental issues that it deserves to have the fullest possible public discussion and for this to be effective it is essential that the views of the museum's scientific staff should be fully heard, together with those of teachers and students in schools and universities both here and abroad, who are intimately concerned with the signal service that the museum has provided in the past.

We can only hope that sufficient pressure can be brought to bear to curb the activities of the Public Services Department and to ensure the survival of the museum's reputation for scholarship in its public galleries. □

How problems in developing the Amazon region have boosted the status of environmental scientists

Brazil learns its ecological lessons—the hard way

The results of opening up the Amazon have been far from those intended: vast tracts of sterile land

SEVEN years ago Brazil's military rulers became the bogeymen of Western environmentalists when they announced that concern for the environment was a luxury of the industrialised countries which developing nations could not afford.

Today the military remains in power; but the message is very different. When President-elect Joao Baptista Figueiredo spoke recently of future development policies for the Amazon region, his references to the need for the "preservation of ecological equilibrium" to which permanent forest areas were "indispensable" could have been lifted from any environmental handbook.

The lesson has been learnt the hard way. Not primarily by listening to scientists and ecologists who, for the past 15 years, have been warning of the destructive effects of uncontrolled development on one of the world's major natural resources; but from experiencing the failure of ambitious plans to "recolonise" the region using techniques developed elsewhere and ill-suited to local conditions.

The result has been a growing awareness in official circles that the environmental impact of development programmes cannot be ignored. "In the past few years all sides have begun to see that poor environmental control can create bottlenecks in economic development," says Dr Paulo Nogueira Neto, a former biology professor who is now head of the environmental protection division of the Ministry of the Interior.

A by-product has been an increased willingness to involve environmental scientists, to whom government planners are now turning as they realise that successful development requires,

inter alia, a firm grounding in detailed knowledge of the behaviour of biological systems and their component parts.

The price of failing to respect such systems has been dramatically illustrated by the effects of the 14,000 miles of highway that have been driven through the Amazon forests like a military exercise over the past decade. The purpose of the roads has been both to open up trade with the continent's west coast, and to encourage the "recolonisation" of the region by settlers who would, it was hoped, convert the biological richness of the forest lands into valuable primary products.

Many of the results have been far from those intended. The roads themselves, disrupting streams and rivers and destroying delicate ecological balances, have produced vast tracts of sterile land. And the settlers, after a year or two of intense cultivation on land from which the trees had been removed, found agricultural yields drop sharply as nutrients were leached from the soil, and soon left to return to the urbanised south.

Thus has developed a practical awareness that, despite all its apparent robustness, the tropical forest is a fragile system in a state of precarious equilibrium; "a desert covered by trees" as it has been called by ecologist Robert Goodland. Less than a fifth of the Amazon region contains productive soil, and agricultural techniques developed in temperate zones have shown themselves frequently inappropriate to tropical conditions.

"The road was a school for us. You have to pay for everything that you do, and Brazil has paid quite a lot for its mistakes," says Dr Antonio Machado, programme director of the National Research Council's humid tropics pro-

gramme, a 3-year \$15 million project on the use of forest resources partly financed by the International Development Bank.

"But although we learnt by the wrong way, we now know much more about the soil, the forests, the water and the weather, and the effects on these of human settlements. And with this information we now have enough to start trying to exploit the forest in a rational way".

One research centre which has been brought into prominence by the new-felt need for scientific knowledge is the National Institute for Amazonian Research (INPA). Founded 20 years ago and financed by the National Research Council, the institute is set in 45 acres of deliberately-untouched secondary forest on the outskirts of Manaus, the main trading town on the Amazon river 1,600 kilometres from its mouth.

Much of INPA's work, like that of the older Goeldi Museum in Belém which is now part of the institute, continues a tradition of study of the unique biological systems of the Amazon region that stretches back through Charles Darwin to Alexander von Humboldt. And previous government antagonism to the opinions of scientists stemmed from the fact that many of the latter tended to see a direct conflict between their interests in "undisturbed" natural systems and the goals of development programmes.

Under its present director Dr Warwick Kerr, who was appointed three years ago on secondment from the University of São Paulo, attitudes have changed. Dr Kerr's outspoken views on social issues have frequently ruffled feathers in the military hierarchy, but he is committed to the belief that INPA's activities must be directed towards the well-being of the people of the Amazon region—part of a com-

promiso which he claims all research institutions have with the society that supports them.

Dr Kerr warns that at current rates of exploitation, the Amazon region's 2.7 million square kilometres of forest would disappear in less than 30 years, and that the urgent need, to which scientists must contribute, is for a pattern of controlled development that takes into account both the potential and the vulnerability of the region's resources.

Referring to the fertile *várzea* regions which receive their nutrients from annual flooding, for example, Dr Kerr says: "the floods, instead of being sources of discomfort, should be looked upon as a blessing and a source of wealth. We should learn how to cope with them, developing systems of housing, of experimentation with livestock, of conserving the forests essential to both fish and to man, and better systems of river transport".

INPA's activities reflect this commitment. There are now over 30 research scientists working at the institute—when Dr Kerr was appointed his arrival is said to have doubled the number of PhDs from one to two—and the work is divided into six divisions: biology, medical sciences, parasitology, agronomy, fish and fishing, and technology.

Each division combines both basic and applied research. In the fish section, for example, research topics range from fish biology to the life-cycle of the manatee, once a plentiful source of meat but now almost extinct through over-hunting; and the agronomy section includes both Dr Kerr's work on the genetics of bees and methods of soil management.

INPA also runs an annual programme of "intensive training" for work in the Amazon. The course, which lasts six months and currently has about 40 students, combines a study of Amazonian ecology and tropical hygiene with groundwork in research methodology (including statistics) and general laboratory techniques.

The growing concern of both local and federal development agencies for the environmental aspects of their programmes has led many to consult INPA for advice. And such interaction has helped INPA to develop a working relationship with government agencies which had initially been suspicious of its attempts to broaden the scope of its activities.

Thus for some time there has been tension between INPA and the Brazilian Agricultural and Ranching Research Bureau (EMBRAPA) over a mutual interest in agricultural research for the Amazon region. Much of this tension was removed, however, by a meeting of the staffs of the two in-

stitutions at the beginning of August, where hostility was transformed into an enthusiasm for cooperation, although with general agreement that INPA should remain responsible for the more basic aspects of the research.

A commitment to "useful" research has not been allowed to swamp more traditional interests of long-term value in the fauna and flora of the Amazon region. A major programme of theoretical ecological studies is being carried out under the direction of Dr Herbert Schubart. And a new venture, which is being organised jointly with the US-based World Wildlife Fund, involves investigating the minimum area that can be isolated as a self-contained ecosystem retaining a full range of biological and genetic diversity.

A local agency responsible for developing methods to exploit the forests resources has agreed to set aside 62 plots of land, ranging in size from one-tenth to 10,000 hectares, for the study. Before the plots are isolated and regularly thereafter for a number of years inventories of the species found on each plot will be compiled by research workers from INPA. "The preservation of the tropical rain forests and the life-forms it contains is a number one priority in our attempts to protect the biological diversity of the planet," explains Dr Thomas Lovejoy, programme scientist of the WWF, a frequent visitor to INPA, and principal investigator of the project.

Both the WWF and INPA have also been contributing to plans drawn up by the Brazilian Institute for Forestry Development (IBDF) to create a series of nature reserves — "conservation units"—in the Amazon region, which at present contains only one of Brazil's eight national parks. The areas recommended as reserves have been carefully chosen by drawing on the scientific records of the critical habitats of different species, and identifying the areas of the Amazon

where these overlap.

The government, partly under pressure from international bodies such as the United Nations Education and Cultural Organisation (Unesco), has already shown itself more willing than in the past to incorporate such proposals in its development plans. A major problem, however, is that much of the land in Brazil is privately owned, and thus outside direct government control.

"The government attitude has certainly been much better than previously. But our main problem is that although we already have eight national parks throughout Brazil covering almost two and a half million acres, less than half a million acres belongs to the government," says Dr Maria Padua, head of the IBDF team that drew up the "conservation unit" proposals.

In the Amazon region, despite attempts to stimulate the development of small-scale enterprises, most of the running has so far been made by large private enterprises. Volkswagen de Brazil, for example, has bought 300,000 acres of forest which it has burnt down for conversion into a giant cattle ranch; and near the mouth of the Amazon an elusive US billionaire, Daniel K. Ludwig, has bought a million acre estate, cut down much of the forest to grow rice and installed a \$300 million Japanese pulp mill.

Dr Kerr's wish for a controlled development that meets the needs of the Amazon people therefore takes on a special meaning. Brazil's growing ecology movement, drawing on biological and environmental arguments, favours a development strategy based on small, relatively self-sufficient communities, allowing the forest to produce a sustained yield of natural products; economic pressures, however, remain weighted towards large-scale enterprises primarily seeking high-level, often short-term, return on investment.

Infra-red telescope will not be ready for Jupiter mission

ONE of the things in life that even the National Aeronautics and Space Administration has been unable to speed up is the hand-finishing of large telescope mirrors. Consequently a current source of embarrassment to the agency is a last-minute delay in completing work on a 120-inch mirror to be installed in its infra-red telescope at Mauna Kea in Hawaii.

The telescope has been commissioned by NASA at a cost of \$6m, and will be used for ground-based observations of planets and other bodies in the solar system to complement data gathered

by spacecraft.

Its first task was to have been to pin-point the position and movement of "hot-spots"—thought to be gaps in the cloud which reveal the higher temperatures, in the atmosphere beneath—on the surface of Jupiter. This information would have been used by the two Voyager spacecraft to direct infra-red sensing equipment and plan the sequencing of operations to gather scientific data.

The two spacecraft were launched last year on courses that take both past Jupiter, and Saturn, and Voyager

It is due to reach Jupiter early next March. However, delays in finishing the mirror, which is being prepared in the workshops of the Kitt Peak Observatory in Arizona, mean that the telescope is not likely to be ready until the end of that month, and completion has been officially scheduled for the beginning of April.

NASA is now planning to rely on the 200-inch Mount Palomar telescope as well as an 88-inch infra-red telescope in Hawaii, to make the necessary observations both prior to and during Voyager 1's fly-past. But officials admit that the quality of the data will be inferior to that eventually expected from the 120-inch telescope.

The delays in the new mirror came first in developing new computer-based procedures for testing the quality of the mirror; and when these procedures were recently completed and the tests applied, it was found that an additional three months' work was still required.

"We are doing all we can to speed things up. But it is the kind of delicate work that does not lend itself to working in shifts; you need a complete crew that is in tune with the project and with each other", Mr Norman Cole, master optician at Kitt Peak, said last week. Mr Cole has also been responsible for the mirrors not only of the 4-metre telescopes at Kitt Peak itself and at Cerro Tololo in Chile, but also of an 84-inch infra-red telescope built by the University of Wyoming with funds from the National Science Foundation, which came into operation last year.

The team preparing the mirror has eight members, and polishers work in the final stages by removing only a few millionths of an inch at a time from selected spots. Mistakes are difficult and time-consuming to correct: "If you go overboard in one touch, then it takes time to blend it back into the surface", explains Mr Cole.

Scientists at NASA's Jet Propulsion Laboratory in California are disappointed that the Mauna Kea telescope will not be ready for the experiments that they plan to carry out when Voyager 1 passes Jupiter, but are confident that the other two telescopes will produce adequate data, and that Mauna Kea will be ready for Voyager 2's fly-past in July.

However the delay is likely to lead to questions in Congress, which was told in 1974, when considering an initial funding request for the telescope, that "no existing telescope" was able to provide the data necessary for planning the Voyager missions, and was assured earlier this year that construction was on schedule.

Dr Bill Brunk, NASA's head of planetary astronomy, admitted last week that the situation was an "embarrassing" one for the agency; "I can only answer that we tried our best to finish it on time". **David Dickson**

Saudi Arabia invests in fishing

THE Red Sea is one of the poorest seas for fishing in the world. It is formed by a deep narrow trench making it very poor in nutrients. In the few areas where there are fish a specialised fishing industry has never been developed because of the many varieties of fish. The Saudi government, however, is trying to modernise the local fishing industry and introduce fish farming along the Red Sea coast. The scheme is being conducted by the Ministry of Agriculture and Water Resources.

In 1976, the ministry signed an agreement with the British White Fish Authority for a four year cooperation programme. So far the programme has assessed the fish resources of the Red Sea and the Persian Gulf and has studied catching methods and ways of increasing fish landings. An aerial survey has shown that there are 72 fishing communities on the Red Sea coast with a fleet of 1,225 boats. Most of these boats are traditional "dhows" which are rather inefficient. The estimated annual landing is 10,000 tons.

Any new additions to the fishing fleet must be easy for local fishermen to use and for local shipyards to maintain. The design criteria have been met by the Cornish boatbuilders Cygnus Marine who have already produced two vessels on an experimental basis. Initial indications are that these small, 10m fishing vessels will play a major role in the fishing industry of Saudi Arabia. A fleet of 25 such boats could increase the catch in the Gulf by 25%.

The Ministry of Agriculture and Water Resources also operates a research vessel, *Ibn Majid*, which has facilities for all forms of fishing. It has

discovered new fishing grounds in the south where there are more nutrients.

The modernisation of the Saudi fishing fleet, however, does not solve the Saudi fishing industry's basic problem—the lack of fish in the Red Sea and the Gulf. Consequently, the idea of fish farming has gained considerable ground. Normally, fish farming is expensive; in Saudi Arabia, however, four factors work in its favour:

- the large market for fish.
- the abundance of unpolluted sea water. Despite an increase in pollution after the re-opening of the Suez canal, the Red Sea remains one of the cleanest seas in the world.
- the abundance of cheap energy for pumping water through fish ponds.
- fish farming would transform large arid coastal plains with no other agricultural potential into food producing areas.

areas

The Fishery Development Laboratory in Jeddah has studied soil samples from probable locations for fish farms. A large area of the Saudi coastline is suitable for the pond/tank method of fish farming. Fish are reared and fed in fenced-off sea pens.

The farms would consist of 25m long ponds perpendicular to the line of the coast. Clean water will be pumped from beyond the reef edge to a header channel from which it will flow by gravity through the ponds before discharging into a channel which runs back to the sea. The ponds will be designed to farm three species: mullet, rabbit fish and a local favourite known as "Bouliti". Fish farming is expected to produce 829 tons of whole fish a year.

Ziauddin Sardar

Stevenson to introduce new DNA legislation in US

SENATOR Adlai Stevenson, chairman of the Senate Subcommittee on Science, Technology and Space, has announced that he intends to introduce new legislation covering research involving recombinant DNA techniques soon after Congress reassembles next January.

According to Stevenson, even though "public opposition to the research has virtually disappeared" as a result of federal actions taken so far, a number of reasons remain to make legislation advisable. These include the fact that federal support of research on

the risks of recombinant DNA techniques will be necessary to keep pace with the development of the techniques themselves; that it remains "anomalous" to restrict one class of researchers but not another, merely on the basis of their location and source of funds (current guidelines now under final revision by the National Institutes of Health would apply only to NIH-funded research); and that "a programme of voluntary compliance by and monitoring of industrial research activities (as proposed in the revised guidelines) is insufficient". □

The Nobel Prizewinners 1978: Physics

A sensitive ear for the Big Bang

Michael Rowan-Robinson writes:

A MODEST and laconic letter entitled "A measurement of excess antenna temperature at 4080 Mc/s" reached the *Astrophysical Journal* on 13 May, 1965. The paper, only 600 words long, describes in a brief, almost brusque, style the first project undertaken by two young radioastronomers since their move to Bell Telephone Laboratories. Using a 20 ft horn reflector built by Bell Labs engineers for the "Echo" satellite project, they had measured the temperature of the antenna when pointing in the zenith (vertical) direction. They had found a temperature of 6.7 K (degrees Kelvin, or absolute), of which 2.3 K was due to atmospheric absorption and 0.9 K was due to Ohmic losses in the antenna. This left 3.5 ± 1.0 K unaccounted for. The two astronomers had worked very hard to eliminate noise sources in their antenna, but could not explain the excess.

Had this paper appeared in the *Bell System Technical Journal* like the other work with the horn antenna, astronomers might hardly have noticed it, as they hardly noticed Jansky's earlier discovery at Bell Labs of radio emission from the Milky Way. Penzias and Wilson did not themselves immediately recognise the significance of their discovery. However they had the good fortune to be near Princeton, where the group led by Dicke and Peebles were only too aware of the significance of a 3 K background. In early measurements with the radiometer which he invented, Dicke had noted in 1946 that the temperature of any cosmic background radiation was certainly less than 20 K. He had then turned to other experiments and to the development of the Brans-Dicke cosmology. By 1965 Dicke, in collaboration with Peebles, had independently reinvented the hot Big Bang model of Gamow, was predicting the existence of cosmic microwave background radiation with a blackbody spectrum (in seminars if not in print) and had two students, Roll and Wilkinson, building a system to measure the temperature of this background.

The plans and dreams of the Princeton group must have been rudely shattered by the news of Penzias and Wilson's discovery. The four of them wrote a beautiful paper explaining the significance of the radiation as the relic of the "primeval fireball" phase of the hot Big Bang, and outlined the physics of this radiation-dominated, opaque

Arno A. Penzias

"To Dr Arno A. Penzias and Dr Robert W. Wilson, Bell Telephone Laboratories, Holmdel, New Jersey, USA for their discovery of the cosmic microwave background radiation."

Robert W. Wilson

phase of the universe's history. This paper appears immediately preceding the one by Penzias and Wilson, with the far more dramatic title "Cosmic blackbody radiation".

Penzias and Wilson included only one very cautious remark on the significance of their 3 K background: "A possible explanation for the observe excess noise temperature is the one given by Dicke, Peebles, Roll and Wilkinson in a companion letter in this issue". Penzias had heard about the Princeton group's ideas and invited them over to Holmdel. Without that visit the only reference to the excess noise might have been the one that

appears in a paper by Penzias and Wilson on the flux from the radio source Cas A, received in its original form by *Astrophysical Journal* on 1 April, 1965: "The equivalent temperature of the antenna when pointed at the zenith is about 7 K, 2.3 K of which is due to absorption by oxygen in the atmosphere".

While it is probably inevitable that Dicke and his group would have discovered the cosmic blackbody radiation within a year or so, it was also inevitable that Bell Labs would sooner or later identify any source of background noise in the microwave region. Earlier they had, through Jansky, identified the effect of the Milky Way in the radio region. It is taking nothing away from Penzias and Wilson to say that part of the credit for their discovery must go to the thorough, professional and single-minded work of the Bell Lab scientists and engineers over the years in developing sensitive receivers and reliable antennae. As Penzias and Wilson note in their historic paper, the 3 K excess is implicit in earlier work by Bell Labs scientists with the same antenna (Degraesse, Hogg, Ohm & Scovil).

The discovery of the microwave background radiation came early in the careers of Penzias and Wilson. It was Penzias's third paper and Wilson's fourth. Subsequently they measured the temperature of the background at 21 cm and 2.6 mm and set limits on its large- and small-scale anisotropy, but the bulk of their later work has been in microwave molecular line astronomy. Penzias has exerted a very considerable influence on the development of this field, always with Wilson's brilliance with instrumentation at his right hand. In collaboration with Jefferts, also of Bell Labs, they discovered the most important interstellar molecule apart from hydrogen—carbon monoxide—and with him and other collaborators they were responsible for the discovery of microwave line emission from 6 other interstellar molecules: CN, SiO, CS, CH₃CN, OCS, and H₂S in the early 1970s. In the past 5 years their main interest has been in the relative abundances of interstellar isotopes and whether these vary from place to place in the Galaxy. They have recently designed and built a novel millimetre-wave telescope. Typically, Bell Labs insisted that the dish be built in New Jersey, rather than at some astronomically more favourable, high-altitude site, Bell Lab's interest in

the telescope is for communication with other human beings rather than with the cosmos.

One curious feature of the story of the discovery of the cosmic blackbody radiation is the ignorance of the scientific literature of all concerned. Neither the Bell Labs nor Princeton workers seem to have been aware of Gamow's idea of a hot Big Bang (*Nature* **162**, 680; 1948) or the prediction of Alpher & Herman in 1948 of a background temperature of 5 K (*Nature* **162**, 774; 1948). More forgivably they had not noticed McKellar's 1941 calculation that interstellar CN absorption line ratios implied a CN

excitation temperature of about 2.3 K (Publications of the Dominion Observatory **7**, 251).

When the Nobel committee opened the doors to astronomy with the 1974 award to Ryle and Hewish, many of us felt that it must be only a matter of time before the discovery of the cosmic blackbody radiation was similarly rewarded. It was one of the astronomical discoveries of the century, transforming cosmology into an exact science and demolishing the already shaky Steady State Theory. The blackbody nature of the spectrum is qualitatively confirmed by the most recent balloon-borne experiment (Woody & Richards,

Phys. Rev. Letters, to be published) and now interest focuses on possible distortions of the spectrum. The isotropy of the radiation both on the large and small scale is well-established apart from the small effect of the Earth's motion in space (see *Nature* **270**, 9; 1977). While we must spare a thought for Dicke and Peebles, who came so close to making this discovery, and who contributed so substantially to its interpretation, and for Jansky, who must surely have shared one of these astronomy prizes had he lived, there is no doubt that the Nobel committee have chosen deserving prize-winners. □

Fifty years of scientific achievement

David Shoenberg writes:

THE "basic inventions and discoveries in the area of low temperature physics" for which Peter Kapitza has been awarded a Nobel Prize in physics were essentially completed over 30 years ago. His many friends and admirers will, however, regard the award as a well merited and, indeed, long overdue recognition of over 50 years of scientific achievement in a much wider field and of the inspiration and guidance he has provided for many generations of physicists in England and the Soviet Union.

As a young man in his mid-twenties he was one of the enthusiastic group led by A. F. Ioffe in Leningrad who were building a school of Soviet physics in the difficult days following the Revolution and its aftermath of civil war and famine. He was already known for his originality and ingenuity in solving practical problems and he was chosen as one of a delegation sent in 1921 to establish scientific contacts with the West.

Kapitza came to Cambridge and was very keen to work under Rutherford in the Cavendish Laboratory. Legend has it that Rutherford was rather cool at first and said the Cavendish was full, to which Kapitza replied by asking what Rutherford regarded as a reasonable experimental error in his work. When told that it was usually 2 or 3%, Kapitza triumphantly pointed out that since there were 30 or so researchers, one more would be just about within the margin of error and this ingenious argument persuaded Rutherford to admit him.

During the 13 years he stayed in Cambridge he became somewhat of a legend not only for his scientific achievements but for the broad sweep of his ideas, his love of argument, his

'To Professor Piotr Leontevitch Kapitza, Institute of Physical Problems, USSR Academy of Sciences, Moscow, for his basic inventions and discoveries in the area of low temperature physics.'

Piotr Leontevitch Kapitza

enormous repertoire of anecdotes (recounted with great verve in a species of broken English which was entirely his own), his absentmindedness and above all his personal charm. At his informal weekly seminar, the Kapitza Club, as it was called, he loved to stir up discussion by asking provocative questions and often new ideas would be thrown up which later proved important.

After some early work on nuclear

physics, Kapitza took up the study of physical properties in very high magnetic fields and at very low temperatures. He developed a novel technique for obtaining fields of over 30 T by discharging a considerable energy into a coil during only 1/100 s, a time short enough to avoid much Joule heating. He liked to boast that he was probably the highest paid physicist in the world since his total work in a year lasted only a few seconds. To attain the low temperatures, he invented a new kind of helium liquefier in which the bulk of the cooling was provided by adiabatic expansion. The difficulty of lubricating the expansion engine at low temperatures was avoided by using a rapid stroke and effectively using the gas as a lubricant. Kapitza's machine was in fact the forerunner of a liquefier developed on similar principles, but for factory production, by Sam Collins at MIT. The Collins liquefier opened up the field of low temperature physics to anyone with money enough to buy a machine and so Kapitza's invention was in a sense responsible for the explosive growth after the war of low temperature physics all over the world but particularly in the United States.

In 1934, soon after the opening of the Royal Society Mond Laboratory, which had been built to house Kapitza's equipment and just as he was preparing to exploit his techniques systematically his work in Cambridge was brought to an abrupt end. During a routine visit to Russia he was unexpectedly refused permission to return to Cambridge and told that he must work in Russia instead. In spite of urgent pleas by Rutherford and diplomatic interventions at the highest level, the authorities were adamant and eventually Kapitza had to submit and

go through the wearisome process of designing and equipping a laboratory all over again. In this he was greatly helped by Rutherford, who persuaded Cambridge University to sell much of the specialised equipment (or duplicates of it) to the new Institute for Physical Problems, as it was called, and Kapitza was able to start work again early in 1937.

Soon after the Institute was operational Kapitza took up the study of the remarkable properties of helium II, the phase of liquid helium below the λ -point (2.18 K). Keesom's discovery in Leiden that it appeared to be a "super-heat-conductor" had caused great interest and in 1938 Kapitza in Moscow and Jack Allen in the Mond Laboratory in Cambridge simultaneously discovered that helium II was also a "superfluid" which could flow through narrow apertures without any driving pressure head. Eventually further experiments, particularly on the thermal effects associated with flow, led to the idea that helium II was a kind of intimate mixture of a "superfluid" which moved completely freely but carried no entropy and a "normal fluid" which did carry entropy and suffered viscous resistance to flow.

This "two fluid model", originally proposed on a semi-empirical basis by Tisza, was a little later more fundamentally established by Landau quite independently, as part of the basic quantum theory of superfluid helium he developed. [Landau was the head of the theoretical group in Kapitza's Institute and his theory proved to be seminal since it not only explained the existing experiments, but predicted several exciting new effects, which were looked for and found under Kapitza's leadership.] It was mainly for this theory that Landau was awarded a Nobel Prize in 1962.

For over 40 years the Institute for Physical Problems has under Kapitza's lively guidance continued to be in the forefront of low temperature research, particularly on superconductivity and the dynamics of electrons in metals as well as on the behaviour of liquid helium.

Kapitza himself, however, has turned to other fields. One technique to which he has made major contributions is the use of expansion turbines to liquefy air on an industrial scale in order to separate oxygen by fractional distillation. But his major activity during the last 25 years and still continuing to-day has been the use of high power microwaves to heat plasma with a view to providing the right conditions for nuclear fusion.

It is remarkable that at 84 he is still as vigorous and enthusiastic as ever. Perhaps another Nobel Prize is yet to come. $\square$

The Nobel Prizewinners 1978: Medicine

From modest beginnings . . .

Hamilton O. Smith, Daniel Nathans and Werner Arber

'To Dr Werner Arber of the University of Basel, Switzerland and Dr Daniel Nathans and Dr Hamilton O. Smith of Johns Hopkins University, Baltimore, Maryland, USA for the discovery of restriction enzymes and their application to the problems of molecular genetics.'

Richard Roberts writes:

THE restriction endonucleases, which have become so familiar to the molecular biologist, have finally come of age with the award of this year's Nobel Prize in Physiology and Medicine to Dr Werner Arber of the University of Basel and to Drs Daniel Nathans and Hamilton O. Smith of Johns Hopkins University. They each played a critical but separate role in drawing attention to these bacterial enzymes which dominate so much present research. Amid the proliferation of sophisticated techniques which characterise modern molecular biology it is the restriction endonucleases more than anything else which have made possible the dissection and analysis of the very large eukaryotic genomes, have allowed spectacular advances in DNA sequence analysis and have triggered the important field of recombinant DNA research. The recent major discoveries of overlapping genes and RNA-splicing were made with the assistance of restriction enzymes and it is becoming increasingly difficult to imagine how it was possible to do without them.

The first hints that restriction enzymes existed came in the early 1950s when Dr S. Luria and his colleagues reported a phenomenon they termed host-induced variation and which is now known as host controlled restriction-modification. They observed that bacteriophages grown in one strain of bacteria were often able to grow only poorly in a second strain. The few progeny emerging from the second strain, however, were able to grow

perfectly normally upon reinfection of the second strain, but now grew poorly upon the first strain. This phenomenon attracted the attention of Dr Werner Arber and by 1962, he and a colleague D. Dussoix, had conducted a series of elegant genetic experiments which provided impressive evidence concerning the nature of this "variation". Together they proposed a molecular mechanism to explain host controlled restriction-modification.

They postulated that certain bacterial strains contained an endonuclease (restriction enzyme) which was able to cleave unprotected DNA, and furthermore that those same strains must contain a strain-specific modification enzyme responsible for the protection of the cell's own DNA from the action of the restriction enzyme. Upon infection by an unprotected bacteriophage the phage DNA was destroyed by the restriction enzyme, except for some small fraction which was modified before encountering the restriction enzyme. Such modified phage were then able to grow perfectly normally upon reinfection of this same strain.

Following the detailed characterisation of the biological phenomena, both in Arber's laboratory and others, this system was analysed *in vitro*. In 1968 Arber and his colleague S. Linn, demonstrated the activity of the *Eco* B restriction enzyme and M. Meselson and R. Yuan purified a similar enzyme from *E. coli* K. It is now known that these Type I restriction enzymes recognise a specific sequence of nucleotides within a DNA molecule, but

cleave the DNA at random positions often far removed from the recognition site. Because of the random cleavage these Type I enzymes have not proved valuable as tools of the molecular biologist. Arber's studies, however, set the stage for the discovery of a second type of restriction endonuclease.

In 1970, Dr Hamilton O. Smith and his colleague K. W. Wilcox, described the outcome of experiments initially aimed at studying recombination in *Haemophilus influenzae*. The introduction to their paper states, "We made the chance discovery of what appears to be a similar enzyme (to the Eco B and K enzymes) in *Haemophilus influenzae*, strain Rd". Thus was described the isolation of the very first Type II restriction enzyme in a discovery destined to revolutionise the practice of molecular biology. In an accompanying paper, written with a colleague T. R. Kelly, it was shown that this enzyme called *Hind* II both recognised and cleaved a specific sequence of nucleotides within a DNA molecule. It thus resembled the Type I enzymes in its recognition properties, but differed significantly in its cleavage properties. It is this difference (the specific cleavage induced by the Type II restriction enzymes) which is responsible for their value to the molecular biologist. The methods used by Smith and his associates to purify *Hind* II and to characterise its recognition sequence have proved generally useful and the majority of the 150 or so restriction enzymes now known to exist have been purified and characterised in a similar way.

From our present perspective it would seem a natural and obvious experimental path to use a specific endonuclease such as *Hind* II to prepare discrete fragments of a DNA genome. However, in the late 1960s gel electrophoresis, a technique critical to current experiments did not enjoy its present popularity. Arber and Smith's experiments used sucrose density gradients or viscometric assays to characterise the products of restriction enzyme digestion, techniques which mask the exquisite specificity of the cleavage products. We must also remember that the major advances in molecular biology had been made in prokaryotic systems where a wealth of genetic back-up had been indispensable to progress. Such was not the case for the small tumor virus SV40 which had just begun to attract the attention of the molecular biologist. Already it was clear that the approaches used for the study of bacteriophages, were not so easily applied to the study of SV40.

Among those studying SV40 in these early days was Dr Daniel Nathans, who worked in the same department as

Smith. After learning of the interesting and unusual properties of *Hind* II and realising the significance of the specific cleavage he set about examining the effects of this enzyme and the enzymes from *E. coli* upon SV40 DNA. Among the techniques chosen to examine the cleavage products was polyacrylamide gel electrophoresis. The results of these studies, carried out with his colleague K. Danna, were published in 1971 and the first gel showing the *Hind* II fragments of SV40 DNA revealed the intrinsic power of the restriction enzymes to allow access to the secrets of the DNA genome. For Nathans had correctly realised that the restriction enzyme cleavage sites could serve as reference points for mapping and could thus replace the conventional genetic markers. In a continuing series of

elegant experiments Dr Nathans has taken advantage of the many facets of restriction enzymes to further his studies of SV40.

As so often happens in science a rather slow and modest beginning suddenly leads to an explosive burst of interest and a rush of new knowledge. Arber's painstaking studies leading to the formulation of the molecular mechanism for host controlled restriction-modification allowed Smith to appreciate the nature of the enzyme activity he discovered in *H. influenzae*. The potential value of this kind of enzyme as a tool for research was realised by Nathans. Today it is scarcely possible to pick up a biochemistry journal without being inundated by the restriction enzyme acronyms. □

Mary Lindley writes from Baltimore:

THE excitement that spread through Johns Hopkins University last week was mixed with a hint of relief that this august institution had its very own Nobel Prize at last. Although other Nobel laureates have been associated with the university, Daniel Nathans and Hamilton O. Smith are the first incumbent members of the faculty to receive the prize.

Unlike almost all other Nobel prize-winning scientists, neither Smith nor Nathans are members of the US National Academy of Sciences. Neither was aware that their work had been nominated for the Nobel Prize, and their first response to the news, received by telephone early in the morning of 11 October, was a mixture of shock and disbelief. After the initial surprise had subsided, however, they were quick to acknowledge the contributions of the colleagues who had helped and influenced them during crucial stages.

Smith recalled how he and a graduate student, Kent Wilcox, became interested in restriction enzymes in 1968, while working on bacterial recombination. In the course of that work they incubated the bacterium *Haemophilus influenzae* with DNA of the bacterial virus P22, and were puzzled by finding that the DNA was broken up. Smith then recalled the work of Werner Arber in Switzerland, who had laid the genetic foundations for an understanding of the process whereby bacteria can destroy foreign DNA (and who now shares the Nobel Prize). And he thought also of M. Meselson's report of a restriction enzyme produced by the bacterium *Escherichia coli* K that could attack and break down foreign DNA.

Smith and Wilcox then set to work to look for such an enzyme in *Haemophilus influenzae*. By the spring

of 1969 they had found and purified it. But then Wilcox was drafted into the army, leaving Smith to continue the work alone. He progressed with much help from Bernard Weiss, working in a neighbouring laboratory, and later with the vital collaboration of Thomas J. Kelly Jr, newly graduated from Johns Hopkins University Medical School. Smith and Kelly soon identified the specific site on the DNA where the enzyme made its attack.

Meanwhile Smith had written to his friend Nathans, then working in Israel, about the interesting enzyme he had found in *Haemophilus influenzae*. At that time Nathans was interested in the relatively unexplored molecular biology of the virus SV40. He recalled that he had been wondering how he could obtain pieces of its DNA. Smith's letter provided the answer. He realised that restriction enzymes that attacked specific sites could be used to manipulate DNA in the same way that the enzymes trypsin and chymotrypsin were used already to analyse proteins.

Back in his laboratory in Baltimore, early in 1970, Nathans confirmed that restriction enzymes could attack the DNA of SV40. Then, together with colleagues K. J. Danna and G. H. Sack Jr, he set about using them to investigate the structure and function of that viral DNA. The work made rapid progress, and eight years later restriction enzymes were among the hottest properties in molecular biology. And then came the early morning phone call.

Of the contributors to this section, Michael Rowan-Robinson is at Queen Mary's College, London, David Shoenberg is at the Mond Laboratory, Cambridge, Richard Roberts is at the Cold Spring Harbor Laboratory, New York and Mary Lindley is on sabbatical from Nature at Johns Hopkins. A report on this year's prize-winner in chemistry, Peter Mitchell, follows next week.

news and views

Are deserts ecosystems?

from Peter D. Moore

THE second International Congress of Ecology (INTECOL) was held recently in Jerusalem* and the choice of venue made it inevitable that some emphasis would be placed upon desert ecosystems. Or should one refer to the deserts as ecosystems at all? N. Meir (Hebrew University, Jerusalem) introduced a controversial, if semantic, note early in the proceedings by stating that since interaction between species is, of little importance in desert communities, the understanding of desert ecology involves simply the sum of autecological information about the component species. The ecosystem concept, he claimed, is of little value in such habitats. This led to the impromptu construction of a desert ecosystem model by H. T. Odum. Evidently, it is still respectable in some quarters to regard deserts in ecosystem terms.

Meir's point (originally made by Darwin) about the low level of interactions between species in deserts, however, cannot be disputed. Plant density is low, mortality is largely density independent, pollination mechanisms are largely unspecialised and mycorrhizal relationships are rare. Seed predation can be very heavy on the other hand; often 90% of a plant's seeds may be eaten by rodents. The animal/plant interaction may be delicately balanced and plant species which are particularly dependent on seed production (r-strategists) may have their populations controlled by seed predators. S. R. Morton (University of California, Irvine) pointed out that there is about three times the number of granivorous mammal species in the North American deserts than in the deserts of Australia. Seed predation in Australia is still very high, however, but birds and ants frequently assume this trophic role. He suggested that this could be due to the late (Oligocene) arrival of rodents in Australia which

would have permitted the diversification of birds and ants into the available niches.

The main constraints on the flora which prevent competitive interactions developing are evidently the high temperatures and lack of water in the deserts and some accounts were given of remarkable adaptations to these extreme habitats. For example, there are the endolithic microorganisms found within porous rocks, such as sandstones and limestones. E. I. Friedmann and R. Ocampo-Friedmann (Florida State University) described such organisms from both the cold deserts of the Antarctic and the hot deserts of Sinai. The outer layer of rock, about 1 mm in thickness, is usually devoid of living matter, but its pores are often blocked by debris. The next 1 mm layer is occupied by photosynthetic algae (often with fungal associates in a primitive lichen symbiosis) or by cyanobacteria or colourless bacteria. Nitrogen is generally not fixed by these organisms, but is available from the rock or from atmospheric fixation. The blockage of pores in the outer layer effectively seals the inner system, leading to water conservation. The advantage of such a closed hydrological system is evident when one considers the data of L. Kappen and O. L. Lange (University of Würzburg) who have shown that some fruticose desert lichens, such as *Ramalina massiformis* demand relative humidities of greater than 90% before there is a measurable net gain in CO_2 . This means that only in a brief period after dawn, following nightly dew absorption, is there a net photosynthetic gain. Such a species can only achieve an annual relative growth rate of $195 \text{ mg CO}_2 \text{ g}^{-1} \text{ dry weight}$. Hiding in the rocks has its advantages.

P. J. Weisser (University of Chile, Santiago) described a rather similar site adaptation in a species of the cactus genus *Thelocophala* from the Atacama desert of Chile. This area is practically devoid of plant life except

along the coast where fog is a major source of precipitation. Here the *Thelocophala* species was found buried beneath a layer of sand 0.5–2.0 cm thick. Presumably the higher humidity of this microhabitat makes it attractive, despite the fact that the photosynthetically active radiation at a depth of 1 cm is reduced to about 1% of that at the surface.

The prevention of water loss, either by habitat specialisation or by more conventional stomate control, has its cost in terms of production. I. R. Cowan (Australian National University, Canberra) considered water use efficiency in plants in terms of the relative sensitivity of transpiration rate and assimilation rate to changes in stomatal apertures. Changing environmental conditions, such as increasing aridity may place those species at an advantage which have the capacity to vary this ratio, for example facultative crassulacean acid metabolism plants.

Such evidence concerning adaptation in desert plants demonstrates how natural selection in these environments has operated, in Darwin's words, through a "struggle with the elements". Evolution in deserts has apparently been dominated by this struggle rather than by competitive interactions between organisms.

Yet this is not the whole story, for it is among desert shrubs that one occasionally finds regularity of dispersion which betrays an underlying intraspecific competitive interaction which limits seedling recruitment. Such regular patterns have been described both in North America for *Larrea tridentata* (see Fonteyn & Mahall *Nature* **275**, 544; 1978) and in Asia for *Zygophyllum eurypterum*. Interspecific interactions are also known, as was described at the INTECOL meeting by A. Danin (Hebrew University,

Peter D. Moore is a Senior Lecturer in the Department of Plant Sciences, King's College, London.

* Held 10–16 September

Jerusalem). Some halophytic species, such as *Reaumuria hirtella* excrete salt from their leaves, thus increasing the salinity of their adjacent soils; other halophytes may have the same effect as a consequence of the shedding of salt-rich leaves. The outcome is suppression of the germination and establishment of glycophytic annuals in their vicinity.

M. M. Caldwell (Utah State University, Logan) provided one example of a situation where one desert shrub had been replaced by another. The competition was between *Ceratoides lanata* (C3 species) and *Atriplex confertifolia* (C4 species) in the Great Basin Desert of North America. Carbon from the roots of *Ceratoides* had $\delta^{13}\text{C}$ values of -22 to -25 , whereas that from *Atriplex* had values of -18 to -19 ,

which is to be expected from C3 and C4 plants respectively. But when soil organic matter carbon was examined for the layers beneath areas now occupied by *Ceratoides* it was found that upper levels had a $\delta^{13}\text{C}$ of -20 to -23 , whereas deeper layers provided values of -15 to -18 . Evidently the C3 species has invaded and replaced *Atriplex* in areas which once it dominated. The C4 system does not always come out on top.

To say that competitive interactions within or between species in deserts are unimportant is thus an oversimplification of the actual state of affairs. It may be that the adaptations which competitive selection has imposed upon desert species are subtle and must be sought at a metabolic level. □

Does Venus have an intrinsic magnetic field?

from C. T. Russell

DECEMBER on Venus promises to be very busy this year. Every 18 months the energy required to launch a probe to Venus reaches a minimum. During this year's energy minimum or, as it is more commonly called, launch opportunity, the USA and the USSR each launched two spacecraft to Venus. The two US spacecraft are scheduled to arrive on 4 December (an orbiter) and on 9 December (a 'bus' carrying one large and three small atmospheric probes). The USSR spacecraft are expected to arrive at Venus in late December and are generally believed to consist each of a lander with a flyby 'bus' rather than an orbiter. Thus in December, we expect that Venus will be visited by six atmospheric probes, two of which will make measurements of the Venusian surface, one bus spacecraft that will burn up in the atmosphere and two that will pass by, and an orbiter which will stay for some time making measurements to altitudes as low as 150 km above the surface.

One of the key questions to be addressed by the orbiter spacecraft is whether Venus possesses an intrinsic planetary field similar to those of the Earth and Mercury. Initial observations with Mariners 2 and 5 and Venera 4 suggested that Venus might not in fact have an intrinsic magnetic field. However, reexamination of some of these earlier data (Russell *Geophys. Res. Lett.*, 3, 125, 1976) and more recent reports of the Venera

9 and 10 orbital magnetic measurements (Dolginov *et al.* *Lunar Science IX*, 256, 1977) have provided evidence in favour of an intrinsic field. The situation is far from clear, and the recent report of plasma measurements by the Venera 9 and 10 wide-angle plasma devices (Verigin *et al.* *Geophys. Res.*, 83, 3721, 1978) does little to resolve this question. There is no doubt from the Venera 9 and 10 data that the obstacle deflecting the flow over the forward hemisphere of the planet is the ionosphere. The authors suggest a stagnation point, or effective obstacle height, of 500 km altitude. In fact it is probably even closer to the planet than this. More recent Russian radio occultation data indicate 260 km to be a more likely obstacle height. Thus any intrinsic planetary field plays only a minor role in deflecting the solar wind. With the solar wind penetrating this close to the planet, charge exchange of the solar wind with the hydrogen geocorona could be an important mechanism in decelerating the solar wind ahead of the planet as suggested by Wallis (Nature, 233, 23, 1971). This mechanism would at a very minimum in the subsolar region weaken the Venus bow shock which slows down and heats the supersonic solar wind before it hits the ionosphere. The authors reject this hypothesis but show no data in the subsolar region. It is still possible that no well-defined shock transition exists in this region.

Verigin *et al.* also report on measurements in the wake region behind Venus. Here they find a plasma

magnetic tail similar in many respects to the terrestrial magnetotail in which a "magnetic field prevents plasma from filling the region behind the obstacle". However, the authors leave open the question as to whether the tail field arises from intrinsic or ionospheric sources.

Verigin *et al.* also compare the Venera data with the Soviet Mars data. In many respects the Mars and Venus plasma measurements are similar, but Mars seems to stand off the solar wind further above the ionosphere than Venus. The authors suggest that this fact indicates that the Martian obstacle to the solar wind is different from the Venusian obstacle, and that the Martian obstacle is indeed an intrinsic field. On the other hand, I find the other evidence for a Martian magnetic field less convincing than for Venus (*Geophys. Res. Lett.*, 5, 81, 1978).

In short the question of the existence of intrinsic planetary magnetic fields for the Earth's two nearest neighbors is still very controversial. We expect that further analysis of the Venera 9 and 10 data and the new data to be acquired in December will resolve this question for Venus. However, there are no plans to my knowledge to probe the Martian magnetic field until at least 1982. At that time the American Galileo spacecraft, as presently scheduled, will whiz by at an altitude of closest approach of 275 km on its way to Jupiter. If I were polled on the eventual outcome of these investigations I would vote yes for a presently operating Venusian magnetic dynamo and no for a Martian dynamo. □

Sex pheromones in bacteria

from J. R. Saunders

THE role of sex pheromones in mating is well established in higher organisms and fungi. In contrast there is scant evidence for such chemical sex attractants in bacteria. In Gram-negative bacteria the formation of aggregates of bacteria during conjugation is well known (see for example, Achtman & Skurray in *Microbial Interactions* (Series B. Receptors and Recognition Vol. 2) 233 (ed. Reissig) Chapman and Hall, London, 1977). The molecular mechanisms involved in genetic transfer during bacterial conjugation have been intensively studied but much less is known of the signalling processes which might initiate contact

C. T. Russell is in the Institute of Geophysics and Planetary Physics at the University of California, Los Angeles.

THE sea moths are a small family (Pegasidae) of marine fishes found only in the Indian and western Pacific oceans, from East Africa to Hawaii. They are enigmatic little animals encased in a hard exoskeleton and with relatively small fins except for the pectorals which are close behind the head and which open fanning out in the horizontal plane. It is these large pectoral fins, wing-like at a first glance, which gave them the name of sea moths. In life these fins are 'fluttered' and the fish moves in short bursts over the sea bed—as W. E. Gosline and V. E. Brock (*Handbook of Hawaiian fishes*, 290; 1960) observe of captive fish "this species acts . . . like a not very large butterfly". Curiously for such interesting-looking animals very little seems to be known of their natural history. Most seem to live in shallow water (down to 200 m) on sandy bottoms, presumably relying on cryptic coloration and irregular swimming action to avoid predators, although one species is described as being red in colour with blue eyes!

While their biology and life style are poorly known there is a wealth of discussion, and disagreement, over their systematic position. Recently, T. W. Pietsch (*Copeia* (3) 517; 1978) has reviewed the previous literature and on the basis of his studies of the skeleton of the sea moths has at last provided firm evidence for their classification. As Pietsch points out two main schools of opinion have existed in the past. The earliest discussions placed them with the pipefishes, sea horses, and their relatives, a stance that was general up to the early twentieth century. However, Günther (*An Introduction to the Study of Fishes*, 482–483; 1880) and

Sea moths pinned down

from a Correspondent

Fig. 1 *Pegasus draconis*. After Day, 1878.

others, impressed by resemblances to certain scorpaeniform fishes (gurnards, scorpion fishes, and especially the poachers) aligned them with this group. Later authors followed this lead, some more tentatively than others, but the general consensus of opinion during the present century has been that they were a distinct order, Pegasiformes, close to but distinct from the scorpaeniform stem.

As a result of an elegant study of the skeleton of *Pegasus*, Pietsch has shown that its upper jaw in particular seems to be unique amongst living fishes although similar, if not identical, to the jaw mechanism of the fossil *Ramphosus* from the Lower Eocene of Monte Bolca and Denmark. There has been general agreement that most of the structures of *Ramphosus* place it amongst the syngnathiform fishes (such as pipefishes). This suggested that *Pegasus* may well be closely allied to the pipefishes and their allies and Pietsch has found a number of significant features which support this view. In addition to the similarities in cranial osteology, the most anterior vertebrae are

elongate which is a feature typical of the syngnathiform fishes; also the gill filaments of *Pegasus* are tufted and lobe-like, not laminate as in most fishes, again a feature of the pipefishes. Pietsch argues convincingly from these and other features that the true relationships of the sea moths lie in fact with the pipefishes and their allies, not with the scorpaeniform fishes.

His further conclusions regarding the classification of these enigmatic little fishes is that they lie intermediate between the two main groups, on the one hand the sticklebacks (themselves a group with a chequered history of classification) and on the other the pipefishes and their allies. All three groups are now united in the order Gasterosteiformes. To allow for the absorption of the new group within the order Pietsch has put forward a new classification in which the sea moths represent a new superfamily. As he points out, this is tentative, as further investigation of several presumed relatives is still required.

It is mildly ironic that these little-known fishes, early examples of which mostly reached Europe as pinned specimens in Chinese insect boxes, have now been placed alongside the sticklebacks and pipefishes which are probably the most intensively studied fishes. The cynic might also point out that in this new classification the sea moths are merely returning to the position they occupied in the mid-nineteenth century. However, on account of Pietsch's careful anatomical comparisons and detailed discussion it seems that this time they will be firmly pinned down—not in insect boxes—but in between the sticklebacks and the pipefishes within the order Gasterosteiformes.

between donor and recipient cells. Although mating signals have been postulated in conjugation little convincing proof has yet been obtained for the presence of specifically 'sexual' attractants. A recent paper from D. Clewell's laboratory (Dunny, Brown & Clewell, *Proc. natn. Acad. Sci. U.S.A.* 75, 3479; 1978) now provides evidence for the existence of a sex pheromone in the Gram-positive bacterium *Streptococcus faecalis*, a normal inhabitant of the gut. Some strains of this organism possess plasmids specifying a number of characteristics including haemolysin production, bacteriocin production and antibiotic resistance. Certain of these plasmids can promote gene transfer by

a process requiring cell-to-cell contact and resembling conjugation in Gram-negative bacteria (Jacob & Hobbs 1974; *J. Bact.* 117, 360; 1974). It has been found that donor and recipient strains of *S. faecalis* form clumps in mating mixtures. Clumping has the effect of bringing donors and recipients into close contact with each other and obviously increases the probability of successful transfer of DNA during conjugation. The formation of these clumps or mating aggregates in *S. faecalis* is apparently induced by an extracellular, heat stable protein of molecular weight between 1,000 and 10,000. This protein, termed a clumping inducing agent (CIA) is produced, perhaps surprisingly, only by recipient (female) cells and not by donors (males). Furthermore, cell-free preparations of CIA will cause donor cells

to adhere even in the absence of recipients. However, CIA is not a physical agglutinating agent but rather a signal (pheromone?) which induces in donors a sequence of events resulting in cellular adhesion. Donor cells must be exposed to CIA for 30 min before clumps are formed. During this time the CIA seems to induce the synthesis of RNA and protein species which are necessary for clumping.

A further interesting property of the *S. faecalis* mating system is that recipients show a reduced ability to elicit CIA once they have acquired a self-transmissible plasmid thereby becoming male. This implies that streptococcal sex factors can regulate CIA either by switching off synthesis of the protein or by inactivating pre-existing molecules of CIA. This would seem to be reasonable in terms of biological econ-

J. R. Saunders is a Lecturer in the Department of Microbiology, University of Liverpool.

omy as it would be wasteful for two male strains to mate with each other.

The mode of action of CIA is itself intriguing. It will be necessary to determine the precise nature of the macromolecules induced in donors by CIA and how these could engineer the clumping response. It is possible that CIA may have an additional function in initiating the mobilisation of DNA for transfer in conjugation. The discovery of CIA in *S. faecalis* should stimulate further research to determine whether sex pheromones are a more general phenomenon amongst bacteria. □

Cosmochemistry and evolution

from A. H. Olavesen and
N. C. Wickramasinghe

AN international workshop on Cosmochemistry and the Origins of Life, organised by University College, Cardiff, was recently held at Gregynog Hall, Wales. A broad overview of the conventional ideas of chemical evolution was provided by C. Ponnamperna (University of Maryland), who pointed to numerous laboratory experiments which showed the production of biochemical monomers from suitably energised mixtures of CH_4 , NH_3 and H_2O . Such conditions are usually postulated to have occurred on the primitive Earth. A. W. Schwartz (University of Nijmegen, Netherlands) provided further evidence for the laboratory production of biochemicals from simpler chemicals. A wide range of biochemicals could be synthesised from 70% eutectic mixtures of HCN in water. For instance all the purines were formed spontaneously in such systems, but pyrimidine synthesis required further ultraviolet-catalysed rearrangements. Phosphorylation reactions were envisaged as being derived from active phosphorylating agents arising from the interaction of apatite with certain other products of the HCN reactions. Reactions involving HCN were thought to have occurred most probably over primitive land masses whilst condensations of formaldehyde occurred in the primitive oceans. The two chemical systems are considered to have come together at the land-water interface.

H. Noda (University of Tokyo) discussed the probability of the appear-

ance of a living system from a mixture of present-day biochemical monomers. It was concluded that random molecular combinations could not have led to the emergence of life with any reasonable probability. A. G. Cairns-Smith (University of Glasgow) pointed out that it was unreasonable to expect the most primitive genetic material to involve such a complex organic polymer as a nucleic acid. He considered it more likely that the crystal structure of simpler inorganic materials, such as clay minerals, might have served as some kind of primitive gene. Clay particles might also have served to concentrate organic materials necessary for the origin of life by surface absorption processes.

M. Paecht-Horowitz (Hebrew University of Jerusalem) demonstrated that certain well-directed polypeptide synthesis could be achieved in the presence of some clay minerals. A degree of polymerisation of up to about 24 amino acids was shown to be possible in this way, and the process was thought to be related to the persistent occurrence of blocks of amino acids in present-day proteins. P. Decker (Chemical Institute, Hanover) discussed the role of autocatalytic systems in the early development of biochemistry. Feedback loops in such systems could achieve steady-state concentrations of certain biochemicals without the necessary participation of enzyme catalysts.

J. T. Wimpey (University College, Cardiff) traced the evolution of microbes from anaerobic prokaryotes to eukaryotic structures. Evolutionary pressures are thought to have forced primitive prokaryotes to develop increasingly sophisticated systems for the utilisation and conservation of essential ingredients. He stated that further biochemical evolution was effectively predetermined at the stage at which the first eukaryotic systems emerged.

The question of the site for the origin of life pervaded the entire meeting. Most participants preferred a terrestrial origin, but a radically different proposal by F. Hoyle and N. C. Wickramasinghe (University College, Cardiff) was the subject of much discussion. Hoyle and Wickramasinghe argued that the set of biochemical monomers necessary for the origin of life is produced in mass flows from stars and is abundant in interstellar molecular clouds. Such biochemicals were mopped up into comets when the Solar System formed and high aqueous concentrations of these materials are maintained for long periods in cometary interiors where they propose that life began. Hoyle and Wickramasinghe suggested that comets still continue to shed living systems onto the Earth in the form of bacteria

and viruses. They then discussed an analysis of influenza attack rates in boarding schools (during the 1978 epidemic) which they claim provides evidence against normal explanations for the spread of this virus.

P. M. Solomon (State University of New York, Stony Brook) reviewed astronomical data relating to galactic molecular clouds. Over 40 molecular species have been detected so far and include HCN and formaldehyde which are also the most ubiquitous of the simpler organic molecules in the Galaxy. It is of interest that laboratory synthesis of biochemicals have mainly involved these two cosmically abundant species.

W. M. Irvine (University of Massachusetts) discussed radioastronomical observations of molecules in comets. Molecules detected so far include HCN, CH_3CN , H_2O and several radicals and ions. There are several radio lines in comets which are as yet unidentified. S. Yabushita (Kyoto University, Japan) discussed theories of cometary origin. K. Nandy and D. H. Morgan (Royal Observatory, Edinburgh) reviewed astronomical observations relating to an ultraviolet interstellar absorption feature centred on $\lambda=2200\text{ \AA}$. The most likely contributors to this band are thought to be small graphite spheres of radii less than $200\text{ \AA}$. N. Nakagawa and A. Sakata (University of Electro-Communication, Tokyo) considered the role of organic molecules with conjugated double bonds in producing the $\lambda 2200\text{ \AA}$ band. They also discussed mechanisms for the formation of such molecules by grain surface reactions in interstellar space, and described laboratory experiments which synthesised such molecules as HC_3N , HC_4N , HC_5N and HC_6N from HCN. □

European geophysics

from Geoffrey M. Brown

OF all the branches of science which attempt to operate under omnibus umbrellas, possibly the most nebulous is geophysics. The spectrum of interest extends from what is curiously referred to as 'solid earth' to the outermost extremities of the terrestrial environment. It is evident that in any assembly of geophysicists in conference there will be no uniting theme. The recent meeting of the European Geophysical Society was no exception. If one had to select a single phrase to summarise the conclusions from the wide coverage of subjects it would be to emphasise progress in techniques. Repeatedly there were references to recent advances in measuring techniques and instrumentation, the development of

A. H. Olavesen is in the Department of Biochemistry and N. C. Wickramasinghe in the Department of Applied Mathematics and Astronomy, University College, Cardiff.

new techniques, the application of numerical techniques, and the refinement of analytical techniques.

In the symposium on active plate boundary regions of the North Atlantic, results of the long-range side-scan sonar GLORIA were presented which confirmed the importance of this technique for tectonic studies of such boundaries. New syntheses of the seafloor spreading history of the North Atlantic have been undertaken, and a major land/sea refraction experiment has shown that in the top few tens of kilometres beneath Iceland normal upper mantle velocities are absent. Partial melting is suggested by an increase in Poisson's ratio with depth.

Thanks to major improvements in palaeomagnetic and rock magnetism analysis techniques, increasing detail is now available on the relationship between successive phases of deformation and metamorphism, and on estimates of parameters such as age and temperature. The general character of the palaeomagnetic record is now so well established that claims to discover new 'anomalies', whether in general palaeomagnetism or magnetostratigraphy, must pass rigorous standards of analysis before they can be considered seriously.

In fluid dynamics, which spans the atmosphere, oceans, mantle and core, much progress has been made by combining field observations, laboratory experiments and numerical analyses. For example, in thermal convection some of the patterns (rolls, hexagons, knots, skewed varicose instabilities) identified in the laboratory, are now recognised (though not yet fully understood) in clouds in the atmosphere and even in small boulder formations in Arctic regions. The effects of condensation on mountain lee waves can now be modelled, whilst on a larger scale this is evidence that the global circulation may be quantised into a number of stable and unstable states, transition being effected by small-scale perturbations. Transition probability is a major problem.

'External geophysicists' were served by three symposia. In one, concerned with the aeronomy and dynamics of the lower ionosphere, the main message was the importance in the height region 70–90 km, of the influence of the neutral atmosphere on the ionised atmosphere. The mechanisms which control this ion-neutral coupling are being intensively studied. In general, the rate of production of ionisation is largely determined by the transport of atmospheric minor constituents, such as nitric oxide, while the rate of loss

of ionisation is strongly dependent on the extent of the water cluster-ion regime which, in its turn, is controlled by the temperature of the atmosphere. Knowledge has significantly advanced through the extension and improvement of both ground-based and rocket techniques. Particular attention was given to results from the Western Europe Winter Anomaly Campaign of 1975–76, which have demonstrated that anomalously high radio wave absorption in winter arises from both increased production and decreased loss of ionisation in the D region. Greatly improved digital telemetry in rocket experiments reveals a fine structure in both the ionisation and neutral gas density in the lower ionosphere. As another example of progress in techniques VHF radar using very short pulses integrated over a second has been used to detect very thin vertically moving layers in the height range 60–75 km.

The other two atmospheric symposia were concerned with different aspects of the acceleration of charged particles in the Earth's environment. The mechanisms which impart the necessary energy to the particles responsible for the aurora have long been elusive. In the symposium on auroral acceleration processes, experimental auroral data covering a range of parameters were compared with theoretical predictions, computer simulations and laboratory studies of plasma acceleration mechanisms. The role of electric fields parallel to magnetic field lines within an Earth's radius is being actively studied. The injection of tracer beams of electrons and ions promises to be an important new technique in the experimental measurement of such fields. Valuable new insights are expected to come from more detailed experimental study of particle distributions, there is need for clarification of the association between accelerated particles and plasma waves. The consensus was that acceleration by quasi-static electric fields is probably the most viable model to date, although it is clear that no single theory is currently capable of accounting for all observations.

In the symposium on the bow shock, consideration was given to the acceleration of charged particles in space in the collisionless region ahead of the magnetosphere where wave-particle interactions transform the cool, supersonic solar wind in the interplanetary medium into hotter, lower speed plasma in the magnetosheath. Very recent measurements aboard the first two ISEE (International Sun-Earth Explorer) satellites, only a few hundred kilometres apart, were presented which enable temporal variations to be resolved from spatial

variations for the first time. These show the presence of ions, sometimes suggestive of beams with rather well-defined angular distributions and with energies up to a few keV, believed to be accelerated by wave-particle interactions at the bow shock. They also show that the thickness of the shock may vary by a considerable factor. The detailed ISEE observations now available in space will remove some of the ambiguities of single spacecraft measurements and should lead to renewed theoretical efforts to understand the intricate physics of collisionless shocks in plasmas.

The EGS is a young society which seeks to bring together geophysicists of all types through its annual meetings. Already detailed plans are laid for the sixth meeting in September 1979 in Vienna. □

Liposomes in the therapy of lysosomal storage diseases

from Gregory Gregoriadis

THE first lysosomal storage disease was identified by Fers in 1963, who found that deficiency in lysosomal X-glucosidase resulting in glycogen accumulation was the underlying cause of the clinical manifestations of Pompe's disease (glycogen storage disease type II). Other lysosomal storage diseases (LSDs) were subsequently discovered which involve the total or partial absence of various hydrolytic enzymes. Initial attempts at enzyme replacement therapy by the direct administration of the missing enzyme isolated from foreign and human sources were disappointing (reviewed by Desnick *et al. Physiol Rev* 56, 57, 1976). Patients set up immunological reactions to the foreign enzymes and some enzymes even fail to enter afflicted cells. Enzyme is also wasted through premature inactivation or loss to irrelevant areas (see *Enzyme Therapy in Lysosomal Storage Diseases* (eds Tager, Hooghwinkel & Daems) North Holland Publishing Company, Amsterdam, Oxford, 1974).

Some years ago liposomes were proposed as suitable enzyme carriers (for a recent review see Finkelstein & Weissmann *J Lip. Res.* 19, 289; 1978).

Gregory Gregoriadis is at the Clinical Research Centre, Harrow.

*Held at the Université Louis Pasteur, 29 August–1 September.

Biochemical and morphological observations showed that, *in vivo*, liposomes could transport agents into the lysosomes of cells (mainly those of the reticuloendothelial system and the hepatic parenchymal cells) by endocytosis. Liposomes protect their enzyme contents from circulating antibodies and prevent them from attacking normal blood components. Work with model lysosomal storage 'diseases' suggested that enzymes transported in this way into lysosomes could degrade stored materials, and recently fibroblasts from a cystinotic patient were partially depleted of lysosomal cystine after exposure to liposome-entrapped cysteamine.

Reynolds *et al.* (page 754, this issue of *Nature*) now present a method for evaluating the liposome approach to enzyme replacement therapy in a naturally occurring LSD, namely feline GM₁ gangliosidosis, which is characterised by a deficiency in β -galactosidase. Skin fibroblasts from cats with GM₁ gangliosidosis were initially pulse-labelled with radioactive galactose (galactose-labelled glycopeptides in the lysosomes of diseased cells are not catabolised over a period of days). Exposure of galactose-labelled cells to liposomes containing β -galactosidase from feline liver is followed by the catabolism of the radiolabelled glycopeptides as a result of the concomitant uptake of the enzyme, apparently through endocytosis of its liposomal carrier. In this and other cases free enzyme fails to enter the cells.

Clearly this is an attractive way to measure the efficacy of a given liposomal enzyme preparation within target cells and could be easily applied in a variety of LSDs. However, degradation of pulse-labelled substrate, obviously concerning newly synthesised materials, may not be characteristic of enzyme action on all accumulated substrate in all intracellular areas. Indeed, it is possible that lysosomes which are either aged or excessively loaded may not be able to fuse with the endocytic vacuoles transporting the liposomes or with young secondary lysosomes which have already incorporated the enzyme. In addition, much of the substrate may be in a physical state resistant to enzyme activity. Therefore, experiments are now needed to show that what Reynolds *et al.* achieved with pulse-labelled fibroblasts can also be achieved with cells at the centre of a given LSD (for example, fixed macrophages from adult Gaucher's disease patients storing glucocerebroside, cardiac or skeletal muscle cells from glycogen storage disease type II patients) by measuring total stored material and examining cellular morphology and function before and after exposure to enzymes.

Extrapolation of results from *in vitro*

experiments to the overall efficacy of the system *in vivo* could, however, be meaningless. In dealing with animals one should consider difficulties related to the journey of the carrier to areas in need of treatment. Liposomes must retain the enzyme while in the circulation and must therefore be designed appropriately. In several LSDs involving tissues other than liver and spleen, the carrier must cross membranes to reach and enter diseased cells (entrance into nerve cells seems improbable at present) and control of its size and surface characteristics will be needed (for a review see Gregoriadis *Nature* **265**, 407; 1977). Reduction in size will also ensure less interference by the liver and spleen, although the chances are that these tissues will themselves be enzyme deficient and participation in uptake is unlikely to be detrimental. Possible toxicity of liposomal lipid components and increased immunogenicity of administered enzymes promoted by the carrier must also be taken into account (discussed by various contributors, *Ann. N.Y. Acad. Sci.* **343**: 1978).

Assuming that enzymes reach target cells and degrade much of the stored material, will this then lead to the organ functioning normally? In adult Gaucher's disease for instance, liver and spleen grow enormously with con-

comitant development of fibrous tissue and other secondary morphological as well as metabolic disturbances, and in several lipidoses nerve cells are probably irreversibly damaged. Our experience (Belchetz *et al.*, *Lancet* **i**, 116; 1977) with an adult Gaucher's disease patient being treated for over 30 months with liposomes containing glucocerebroside: β -glucosidase isolated from human placenta, provides evidence that the enzyme is acting in the liver, as the transient pain in that area after each injection is proportional to the amount of enzyme given. Significantly, the patient's health has stopped deteriorating since treatment began and there is some reduction in abdominal pain due to liver pressure as well as some improvement of reticuloendothelial system function. In the only other case of LSD treatment with liposomes some reduction in liver size was also reported. Unfortunately, however, the patient (an infant with glycolipidosis type II injected with fungal amyloglucosidase) died before any valid conclusions could be drawn (Tyrrell *et al. Brit. Med. J.* **2**, 88; 1976). A major difficulty in the follow-up of LSD patients is our inability to measure progress in serial biopsies as there are gross differences in the substrate content and morphology of various parts of the tissue. □

Radiation research in Scandinavia

from R. B. Cundall

A RECENT conference* in Denmark covered most of the topical and debatable aspects of radiation science, in addition to what now appear to be well established and steadily progressing areas, such as electron trapping, excited states, and free radical reactions. The conference was attended by delegates mainly from Scandinavia, and served particularly well in the attention which was directed to controversial and timely topics. These were the disposal of nuclear waste, industrial applications of high energy radiation, and radiation effects on DNA.

Legislation recently introduced in Sweden on the disposal of spent fuel and wastes from nuclear power generation has served to concentrate much effort and thought on this subject. Papers by F. Lofveberg (Nuclear Fuel Safety Project, Sweden), A. Lund (Nykoping, Sweden), J. A. C. Marples (AERE, Harwell, UK) drew attention to the nature and properties of vitrified waste and the thought-provoking prob-

lems of storage facilities which may be used for periods of more than 10⁶ years. The possibilities of leaching, temperature effects and washing which could be significant have been examined but the results indicate that the radiation and physical stability of glass waste is of no concern. Presentations on transport of radioactive isotopes through different types of terrain also provided reassurance. This type of work is important for the safe exploitation of nuclear power, especially since the time scale of possible hazards is outside previous human experience and could involve larger quantities of dangerous material than is generally appreciated, although so far the radiation experts' findings are encouraging.

Opposing views are even more firmly established concerning possible industrial applications of ionising radiation to chemical synthesis and modification of physical properties, especially those of polymers. J. Silverman (University of Maryland), a well-known exponent of radiation technology, spoke with enthusiasm and probably surprised the delegates with economic statistics showing possible annual turnover

*6th Conference of the Nordic Society for Radiation Research and Technology, Hirtshals, Denmark, 28-31 August 1978.

"SUDDENLY, pear blossom on every tree/As though the wind of Spring came upon us last night." With these words so welcome to a people that has just passed a long and dreary Winter in science (see *Nature*, 274, 834; 1978), a new Chinese journal, *Ziran Zazhi*, greets the world.

Ziran Zazhi means simply 'Nature Magazine'. It is a monthly of about 60 pages and its first issue came out in May. Its aims are: to get better acquainted with Nature, to remould Nature and to exact greater freedom from Nature. Its editorial policy is to "let scientific truth develop and grow through contention". It covers both physical and biological sciences and is very much like this Journal in having as its main content Articles, Research Letters and Nature Information. In addition, it has two more popular sections, Explorations in Nature and Riddles in Nature.

The Research Letters at the moment account for only 10% of the pages, but they are given pride of the place. Compared with the Letters of this Journal, they are somewhat shorter, just as technical, and cover as wide a spectrum, except perhaps for a slight bias toward particle physics and systems analysis in the issues so far published. Arguably the most original Letter so far is a report of some experimental results on the physical basis of the traditional *yunqi* therapy—the curing of disorders through the passing of *qi* (pneuma) from doctor to patient without bodily contact. Though not as well-known as acupuncture, this form of therapy has its believers and followers among

Nature: Chinese style

from T. Kiang

the Chinese people. It goes something like this: the doctor does a sort of breathing exercise; a few minutes later, he has a feeling of congestion (stage 1) which may last a couple of minutes; he then has a feeling of release (stage 2) lasting another couple of minutes. The traditional 'theory' is that, during stage 2, the doctor's *qi* is emitted through certain specific points called *xuwei* and enters the patient's body through some other specific *xuwei*, effecting the desired cure. What the experimenters found was that, during stage 2 but not during stage 1, the far infrared radiation at 1.2 cm from the active *xuwei* of the doctor showed a slow (down to 0.05 Hz) modulation of large amplitudes (up to 80%). They also found abnormalities in body electricity near the *xuwei*, during both stages. Furthermore, from chemical analysis of tissues from a number of corpses, they found that the tissues at the *xuwei* points had a marked excess of nickel. These findings have all the hallmarks of pioneer work and their preliminary character makes the Research Letter their perfect vehicle.

The Articles form the mainstay of ZZ. Each covers in depth a certain topic—Mössbauer spectrometry, the red tide and laser chemistry have been covered amongst others—and is written by an acknowledged expert in the field. In regard to the degree of

technicality, the Articles of ZZ resemble more their counterparts in *Endeavour* than those in this Journal.

Nature Information consists of extracts of articles from other current scientific periodicals, notably, *New Scientist*, *Science News*, *Science* and *Physics Today*. Here, as with Articles and Research Letters, astronomy and astrophysics have their due share, but these are even more prominent in the Explorations in Nature section. In one form or another, readers have been informed of recent findings made in China and abroad on the origin of the Solar System, black holes, gamma-ray bursts, neutron stars, rings of Uranus and quasi-stellar objects that are at the same time double radio sources. For many of the Chinese investigations, the full-length papers are now available in English in the translation journal *Chinese Astronomy*.

The Riddles in Nature which have appeared so far have dealt with the life-span of single cells, magnetic monopoles and the μ -particles I, as a professional astronomer, found the first most intriguing—which the editors of the multidisciplinary *Ziran Zazhi* may feel gratified to know.

The appearance of *Ziran Zazhi* is a heartening event. Just how heartening can perhaps be appreciated only by the Chinese scientific community. It is one of the signs that the country has begun her 'New Long March' towards modernisation through science and technology. □

T. Kiang is at the Dunsink Observatory, Castleknock, Eire.

reaching billions of dollars in the USA alone. Two hundred electron accelerators and 60 industrial ^{60}Co units are already in use throughout the world. It is clear that academic workers in the radiation science area are ill informed on the industrial possibilities; for example, well publicised applications to the synthesis of detergents seem to have failed whereas the radiation-induced crosslinking of rubber for tyres has apparently been very successfully applied by the Goodyear Company in the USA. Discussion revealed caution and open scepticism from many delegates about the current state of such technology, although specific and restricted areas of application, sterilisation for example, are undoubtedly extremely useful. Industrial application depends crucially on detailed investiga-

tions and these were exemplified by papers on polyethylene/SiO₂ composites, polystyrene sterilisation, and electrical insulation. J. Rabani's (Hebrew University, Jerusalem) interesting paper on solar energy exploitation was more of hope and problem definition than achievement. Photoelectron transfer effects which are probable mechanisms for achieving the formation of H₂ and O₂ from solar irradiation of water are likely to be enhanced by polyelectrolytes, ion exchangers and micelles. The use of polyelectrolytes seems to offer many significant advantages since they inhibit back electron transfer reactions and help fulfil the requirements of energy storage.

The interest in cellular and sub-cellular radiobiology is largely centred on the effects of radiation on DNA, and the effect of oxygen was the main theme of the presentation. The difficulties of experimentation in this clinically important field were highlighted by the

paper of B. M. Cullen and J. W. Boag (Hammersmith Hospital & Institute of Cancer Research, Sutton, UK) which showed how errors of technique can provide misleading results. Photoelectrons formed in higher yields when argon was used instead of nitrogen as deoxygenating atmosphere caused reductions in cell survival.

The still incomplete knowledge on reactions of the biochemically significant O₂⁻/HO₂ system was also examined. The paper by G. Czapski (Hebrew University, Jerusalem) showed the increasing involvement of physical chemists in problems of radiation biology. The interdisciplinary approach is proving seminal, the previously accepted so-called Haber-Weiss reaction is discounted but an alternative explanation remains to be found.

No enzyme has attracted the radiation scientist more than superoxide dismutase. The reasons are its selectivity towards the O₂⁻/HO₂ system and

R. B. Cundall is Professor in the Department of Chemistry and Applied Chemistry, University of Salford.

its convenient properties for study by pulse radiolysis. E Lengfelder (Strahlen-biologisches Institut der Universität, Munich) showed how several synthetic metal-containing complexes also display marked superoxide dismutase activity.

As appropriate for a meeting in Scandinavia significant 'state of the art' papers on DNA by Graslund and G. Ahnström (Wallenberg Laboratory, Stockholm) and positronium (O. Mogensén, Riso Laboratory, Denmark) were presented. The effect of radiation on DNA has been and remains the most important aspect of radiobiology and it is essential that effects of individual free radical reactions, strand breakage, chemical modification and biological effects are examined and correlated. Ahnström emphasised that effects on repair processes could be crucial to radiosensitivity. Radiation damage to DNA prevents enzymic cleavage of oligonucleotides, and suggests a new method for studying radiation effects in DNA (D Schulte-Frohlinde and C von Sonntag, Max-Planck-Institute, Mulheim).

The successful application of resonance Raman spectroscopy to pulse radiolysis was a notable achievement of the Riso group (R Wilbrandt, N H. Jensen and P. Pagsberg) and details of the structure of (SCN)₂⁻ have been determined by its use. The powerful technique of pulse radiolysis is considerably improved by transient detection methods which allow better structural identification. □

A hundred years ago

In a lately-issued number of the *Proceedings* of the American Philosophical Society, Prof Cope has given an account of the collection of fishes made by Prof Orton at various points on the head-waters of the Amazon. Species of the genera *Belone* and *Tetrodon*—characteristically marine forms—are here recorded as having been obtained in these districts 2,500 miles from the mouth of the river—thus showing how far marine animals will penetrate into, and become ultimately acclimatised in, fresh waters.

The existence of the true heath plant in North America was for a long time considered very doubtful, and its detection in New England some years ago is a matter of much interest. The published localities hitherto are Newfoundland, Nova Scotia, and Massachusetts, but, according to the *Bulletin* of the Torrey Botanical Club, Dr Hexamer, of Newcastle, has lately found a few plants of it near Egg Harbour, New Jersey.

From *Nature* 18, 24 October, 682; 1878.

Producing more food

from W. S. Wilson

THE inexorable increase in the world's population without a commensurate increase in food supplies has prompted a re-examination of production methods, post-harvest care of produce and even the types of food consumed. These considerations were well to the fore at the XXth International Horticultural Congress*. The wide range of scientific disciplines involved focused on fruit, vegetables, ornamental and amenity plants and post-harvest horticulture. The last was a new feature of these 4-yearly gatherings and reflects the growing concern for quality produce in developed countries and the need to overcome scarcity in many developing countries, including India where per capita consumption of vegetables is only one-third of that recommended by dieticians.

Nowadays vegetables and fruits are survival foods in some countries and health-giving foods in all others. Vegetables provide more carbohydrate, vitamins and minerals per unit area of land than other type of crop. Some, such as the soya bean, are an inexpensive source of protein. A spectacular way of intensifying vegetable and fruit production in some countries was given by E C. Quisumbing (University of the Philippines) when he described the growth of coconuts under which were growing bananas, under which were grown pineapples beneath which were grown sweet potatoes, all on the same piece of land at the same time. This arrangement resulted in quadrupling the potential yield of the land and increasing the income of the small farmers.

Apart from management aids to increasing production and improvement of produce quality, advances in fundamental knowledge and technological applications which make handling and mechanical harvesting easier, were reported. In the temperate fruit section, the emphasis was on the adjustment of tree density by breeding or hormonal treatment to render the fruit easier to harvest mechanically. This trend is particularly advanced in Australia and New Zealand, countries with small labour forces. Plant breeders have introduced dwarfing characteristics enabling more trees to be grown more productively per hectare. Another method for increasing yield of apple cultivars, described by A. I. Campbell (Long Ashton Research Station, Bristol) was the exposure of dormant scions to gamma irradiation under water to form stable mutants. Physiologists have been able to control growth characteristics

by hormonal regulation. Thus ethylene can be used to increase flowering, offset biennial bearing, prevent pre-harvest fruit drop and advance or delay fruit maturity.

The most important advances in vegetables have also been related to systems methods of production. W. L. Sims (University of California, Davis) outlined a sophisticated system for tomato production involving an integrated breeding programme, uniformly flat seedbeds, simultaneous ripening and a single harvest operation. This system is appropriate to California but other systems applicable to other regions can be devised. For less ambitious objectives crop increases can be achieved by deeper loosening of non-compacted soil or by hormonal treatment of crops to achieve greater lateral proliferation of roots to explore compacted soil. Allied with these measures is a rapid method of forecasting fertiliser requirement such as that described by D J Greenwood (National Vegetable Research Station, Wellesbourne, Warwick). This involves assessing inorganic nutrient ions in plant sap with test strips and in the soil filtrate with reagents prepared in tablet form. A notable achievement in vegetable breeding is the production of high protein potatoes (over 10% protein) for use as animal feed in Australia.

The main concern of the section on ornamental plants was to devise the best way of educating the community to appreciate plants, gardens and landscape. For over 300 years botanic gardens have been preoccupied with taxonomy and amenity horticulture. In the future, these institutions and horticultural societies should be more concerned to inject greater diversity into horticulture by, for example, introducing plants from the southern hemisphere into northern countries.

In the post-harvest section a paper by M. A. Perring (East Malling Research Station) on mineral and physiological disorder in apples explained how the physical and chemical composition of apples is influenced by soil type and management, environment and nutrition. In this connection, bitter pit in apples caused by calcium deficiency can be alleviated by dipping the fruits in a calcium chloride solution. Preservation of condition in easily-perishable vegetables can be achieved by covering the crop with low cost polyurethane foam in cool stores.

Australia provided an excellent venue for the Congress, offering a wide range of wild flora alongside a diverse horticulture in which science and technology are complementary. □

review article

The biochemistry of complement

R. R. Porter & K. B. M. Reid

MRC Immunochemistry Unit, Department of Biochemistry, Oxford University, South Parks Road, Oxford, UK

Current biochemical studies of the complement system are illustrated by description of the activation of complement by the classical pathway after interaction with antibody aggregates. This is described in terms of the structures of the components involved, their assembly and the mechanism of activation.

IN the blood of vertebrates several activation systems have been recognised which are essential for the survival of the animal. These include blood clotting, clot lysis, the renin-angiotensin and kinin systems and complement; all are dependent, at least in part, on the sequential activation of a series of proteolytic zymogens¹.

Complement is the most complex of these systems and it is of interest for several reasons. First, as recognised 80 yr ago², the complement system is responsible for the destruction and elimination of foreign material from the body, notably bacteria and viruses. This usually occurs after the interaction of antibodies with the foreign organisms or substances, and complement is thus the effector mechanism in the immune defence against infection. Complement may also be activated by complex polysaccharides³ such as yeast or bacterial cell walls before reaction with antibody and hence it can form an immediate defence against infection before the development of immunity⁴. Second, receptors for activated complement proteins, such as the third component C3 are present on lymphocytes, macrophages and some other cells⁵⁻⁷, and there is evidence, as yet incomplete, that the lymphocyte C3 receptors may play an important part in the interaction of the different classes of lymphocytes or their precursor cells⁸. The interaction of lymphocytes such as the B and T cells is necessary for the occurrence of the immune response and it is possible that complement may play a central part in the immune response as well as being the major effector mechanism. Third, it has been found that several complement proteins are coded for by structural genes which map into the major histocompatibility locus in man and in mice⁹. The biological significance of these findings is uncertain, but it has been suggested¹⁰ that it may imply that some complement proteins have a role as surface proteins, as all the other proteins coded for by this gene complex apparently do.

Not surprisingly, therefore, interest in the complement system has increased greatly, and the progress in isolating and characterising the various components has led to attempts to determine their structure and the biochemical mechanisms of the activation system. It is highly complex and includes about 20 serum proteins, most of which are part of the activation sequence, but control proteins are also included; these inhibit different steps or inactivate some of the components. The biological importance of the system has been emphasised by the finding that it is probably present in invertebrates and has been conserved throughout evolution¹¹ to such an extent that some components are interchangeable between species as distant as frog and guinea pig¹². The complexity of the system may be due to the multiple role of some components as suggested above, but also,

as with the other activation systems of the blood, it is important that they are activated rapidly when needed but never activated accidentally. A cascade system with each step able to be inhibited offers a system of rapid activation coupled to a series of fail-safe controls.

There are several features of complement which are most unusual. For example, C1q, the component which interacts with aggregated antibody, has a unique structure which is half globular and half collagen-like¹³. Also, several of the proteases involved in the complement system are formed only after activation of the protein possessing the catalytic site and association of this protein with one or more other proteins which thus determine the specificity of the activated enzymatic site^{14,15}. No attempt will be made to review the whole complement system, but only a few of the more uncommon features will be described, of the structure and activation of the early components of complement after interaction with aggregated antibody.

Activation of the complement system

Activation of the complement system can take place by two distinct pathways, the classical and the alternative pathways: here we shall concentrate on the classical pathway. Both pathways have the same terminal components, C5 to C9, which are directly responsible for membrane damage. The difference between them lies in their early-acting components and thus in the manner by which they are activated by immune complexes or other factors. The sequence of events in the activation of the early components of the classical pathway is shown in Fig. 1. When C1 is bound to antibody aggregates it becomes an active protease, C1_s, and catalyses the activation of C4 and C2 which together form another protease C4₂ (ref. 14). This enzyme is also known as C3 convertase because it activates C3, some of

Fig. 1 Activation of the classical pathway by antibody-antigen (Ab-Ag) aggregates.

Table 1 Early acting components of the classical pathway

Component	Molecular weights of				Enzymatic site present in activated form	Approximate serum concentration (mg l ⁻¹)

* Chains obtained after reduction and alkylation of disulphide bonds.

† C1q is composed of nine subunits, each subunit consisting of two disulphide-linked chains (see text and ref. 13).

‡ C1r is present as a dimer of two identical, noncovalently linked chains in serum.

which associates with C3 convertase to form C423; which in turn activates C5. Some properties of components C1 to C5 are shown in Table 1. In the alternative pathway of activation, which can be started when polysaccharides are added to serum without interaction with antibody, other components lead to the formation of a different form of both the C3 and C5 convertase enzymes¹⁶. The cleavage of C5 is considered to be the last enzymatic step in the activation of complement by either pathway. The final event is the formation of the C5b6789 complex, apparently by self assembly¹⁷ in the process of which part of the complex becomes inserted into cell membranes^{18,19}, thus causing the membrane lesions seen in electron microscopy studies^{20,21}.

Structure and properties of the first component of complement

C1 occurs in serum as a weak association of C1q with a tetrameric complex of C1r₂-Ca²⁺-C1s₂ which is formed in the

presence of Ca²⁺ (refs 22, 23). Interaction of C1 with aggregated antibody is through C1q (ref. 24) which binds in the absence of C1r₂-Ca²⁺-C1s₂ to the second constant domain (N terminal half of the Fc) of IgG (refs 25–30). The C1r₂-C1s₂ complex binds to C1q on the antibody through C1r, as C1r alone, but not C1s, interacts with antibody bound C1q (refs 31, 32).

C1q is a 400,000 molecular weight protein^{33–35} formed from 18 peptide chains 6A, 6B and 6C, each of about 200 amino acids and containing 12, 8 and 4% CHO respectively³⁵. Amino acid sequence analysis showed that these three types of chain are very similar and each has about 80 residues of typical collagen-like sequences starting close to the N terminal end^{36,37}. The N terminal sequence of the B chain (Fig. 2) between residues 6 and 89 has the repeating triplet Gly-X-Y, where the residue in the Y position is often hydroxyproline or hydroxylysine. The A and C chains have similar collagen-like sequences between residues 9 and 89 and 3 and 89, respectively. (Numbering of residues is based on B chain sequence, Fig. 2.) The repeating triplet sequences in each chain are, however, not quite continuous. In chain B, alanine not glycine occurs at position 9; in chain A

Fig. 2 N-terminal amino acid sequence of the chain of human C1q. The sequences are given in the single letter code: A, Ala; C, Cys; D, Asp; E, Glu; F, Phe; G, Gly; H, His; I, Ile; K, Lys; L, Leu; M, Met; N, Asn; P, Pro; Q, Gln; R, Arg; S, Ser; T, Thr; V, Val. The numbering is based on the B-chain sequence. A gap has been made between positions 38 and 39 in the B and C chain sequences to allow for the 'extra' threonine in the A-chain sequence. A triplet gap has been made between residues 42–44 in the A and C chain sequences, as this seems to give the optimum alignment for maximum homology. The sequences shown are from refs 36 and 37 except for residues C41 to C97 which are unpublished data (K.B.M.R.). Each chain is approximately 200 residues long. * Denotes a hydroxylated residue.

threonine is inserted in between positions 38 and 39 and alanine replaces glycine at position 36 in the C chain. However, with the exception of these small changes at the beginning and in the middle, there is a continuous sequence in all three chains of which the similarity to collagen is increased by the presence of glucosylgalactosyl disaccharide substitutions on the hydroxylysine residues^{33,38}. The sequences of the remaining 110 noncollagenous residues in each chain, which are known, are very similar and each has one intrachain disulphide bond. Collagen fibrils are formed from three peptide chains each in a minor helix, which associates noncovalently to form a major helix with well characterised dimensions³⁹. This makes it possible that the 18 chains of C1q are associated through their collagen-like sections to give a hexameric structure of six fibrils with six globular heads formed from the C-terminal halves of each chain. Such an arrangement would be consistent with the remarkable structure of C1q as seen in electron microscopy, showing each molecule to resemble a bunch of six tulips with the lower half of the stems held together and branching in the upper half to give six separate stems each of which is joined to a globular head⁴⁰⁻⁴².

C1q, when reduced and electrophoresed on polyacrylamide gels containing sodium dodecyl sulphate, shows the three expected polypeptide chains A, B and C in equal amounts which, though of similar size (23,000 MW), separate probably because of their differing carbohydrate content³⁵. However, if electrophoresed before reduction, two subunits can be seen which again, though of similar molecular weight (46,000-48,000), separate clearly on the acrylamide gels. The apparently larger subunit contains the A and B chains and the apparently smaller subunit only the C chain^{13,34}. That is, they correspond to an A-B dimer and a C-C dimer and yields show that there must be six AB and three CC dimers¹³. The association of these nine subunits to yield the hexameric structure seen in the electron-microscopy studies may be achieved in the way described in Fig. 3. A triple helix could be formed between the collagen region of one of a pair of C chains and the collagen regions of an AB dimer; in this manner three pairs of triple helices would be formed. Then the association of these three pairs, again non-covalently, would give the complete hexameric structure, each of the globular heads being composed of the C-terminal 110 amino acids of an A, a B and a C chain (Fig. 3)¹³. The breaks in the Gly-X-Y sequence mentioned above and occurring at positions 39 and 36 in the A and C chains, respectively, could account for the bend in the collagen-like fibrils seen midway along the stems of the molecule, as a true triple helix cannot be formed in this area of the molecule because of the prerequisite for glycine as every third residue³⁹. Measurement of the dimensions of the molecule on the electron microscope picture and calculation from the known lengths of the Gly-X-Y triplet sequence in collagen agree well¹³. It seems likely, therefore, that the postulated structure is correct.

C1r and C1s are very similar proteins, each a single polypeptide chain of about 83,000 molecular weight differing only in that C1r dimerises whereas C1s remains as a monomer in solution irrespective of the presence of Ca^{2+} (refs 43-45). Together they form a tetrameric complex in the presence of Ca^{2+} , as in serum. On activation, they are both hydrolysed to give two disulphide-linked peptide chains of 56,000 and 27,000 molecular weight, but they remain in a tetrameric complex. C1r and C1s are very similar in amino acid content and also in sequence as far as this is known, and it is considered likely that one arose from the other by gene duplication. Both activated subcomponents are typical serum esterase proteases inhibited by diisopropyl fluorophosphate⁴⁶⁻⁴⁸ and both have a characteristic N-terminal sequence present in the 27,000 molecular weight chain (which is the chain containing the catalytic site), showing obvious homology with other serine esterase proteins⁴⁵. C1r and C1s differ markedly in enzyme specificity, however, and C1s is the only known substrate for C1r. C1s, but not C1r, will activate C2 and C4, and C1s will also hydrolyse several peptide substrates, showing a plasmin-like specificity⁴⁵.

Fig. 3 Proposed peptide chain structure of C1q. The dimensions given are averages of those of Shelton *et al.*⁴¹ as estimated from electron microscopy studies. ~, Proposed triple helix sections, that is, collagen-like regions of molecule. The following comparison can be made. Length of collagen-like fibre + fibril-like endpiece = $115 + 112 = 227 \text{ Å}$. Length of triple helix proposed from sequence studies = $80 \times 2.9 = 232 \text{ Å}$.

Structure and properties of components C2 to C5

C4, a major complement component (400 mg per l serum) has three disulphide-linked peptide chains of about 90,000, 75,000 and 30,000 (refs 49, 50), although recent evidence suggests that it may be synthesised as a single peptide chain of 200,000 molecular weight⁵¹. Some of this precursor molecule, which is very similar to C4 as judged by antigenic specificity, but which has no haemolytic activity, also seems to be present in serum⁵². The Ss protein identified first as a polymorphic protein in mouse serum which is coded for by a gene in the major histocompatibility complex⁵³, has now been identified as C4 (refs 54-57). Human C4 has also been shown to be coded for by a gene which maps into this complex on chromosome 6 (ref. 58).

C2 has been one of the most difficult components to isolate, as it is present at only 15-20 mg per l of serum and is exceptionally vulnerable to proteolysis during isolation. Isolation has now been achieved^{59,60}, and in confirmation of earlier work^{61,62} it was found that C2 is a single-chain protein of about 100,000 molecular weight which is split on activation to two chains, not disulphide-linked, of 70,000 and 30,000. The activated protein may be a protease, possibly of a serine esterase type, though not

readily inactivated by diisopropyl fluorophosphate and, surprisingly, with the catalytic site in the larger chain⁶³. Proteolytic activity is only apparent when C2 forms a complex with C4 and then its specificity seems to be restricted to hydrolysis of C3; hence the term C3 convertase¹⁴. C2 is also polymorphic and is coded by a gene mapping into major histocompatibility complex in humans⁶⁴.

C3 (refs 65–67) and C5 (ref. 68) are proteins of about 180,000 molecular weight, each containing two chains of about 105,000 and 75,000 molecular weight. Such structural evidence as is available⁶⁹ suggests that C3 and C5 are so similar that, as with C1r and C1s, they probably arose by gene duplication. On activation, both lose a peptide (C3a and C5a) of about 10,000 molecular weight from the longer peptide chain. In each case the small peptide has anaphylactic activity^{70,71}. Only C5a has chemotactic activity⁷². C3, however, is present in much higher concentrations in serum, 1–1.5 g l⁻¹, and is equivalent in concentration to the sum of all the other complement proteins. It seems that C3, as C4, may be synthesised as a single chain precursor molecule⁷³.

Assembly of the component by addition of antibody-antigen aggregates to serum

The mode of assembly of these serum proteins on aggregated antibody and the mechanism of their subsequent activation are far from clear, but several features are beginning to be understood. The antigen seems to have no specific role and whole complement is activated equally well either when antibody is precipitated by addition of a soluble antigen such as ovalbumin, or when antibody-coated red cells are added to serum⁷⁴. Quantitatively, complement consumption per 1,000 molecules of antibody added is 1.5–2 times higher for antibody-coated cells than for antibody aggregates. However, this difference is small and may simply be because antibody molecules spread on a cell surface are more accessible than those in aggregates.

The binding of the first component to the antibody is very efficient (>95% in antibody excess) and activation is complete⁷⁴. C4 is rapidly activated by C1 but only a small fraction (<10%)^{74–76} is bound to aggregates or antibody-coated cells, the rest becoming inactivated in the serum (Fig. 4). Binding of C4 to antibody-coated cells is 10–15 times more efficient than to antibody aggregates, but the number of C4 molecules which become effective as judged by their capacity to form C3 convertase when C2 is in excess is only about twice as great⁷⁴, which is comparable to the difference in C1 binding. This suggests that most of the C4 binds to the cell surface rather than to the antibodies, and little of this is able to form C42 and continue the complement sequence. However, although it has been shown¹⁴ that C4 can bind to red cells in the absence of antibody, it can also apparently cause lysis on the addition of C2 and C1s followed by the later components of complement. The C4 on the cell surface can therefore take part in the activation sequence, presumably by binding C2 and forming C3 convertase. In this experiment, C2 would be formed in solution close to the cell-bound C4. When the antibody is on the cell surface the C1 complex containing C1s would be bound to the Fc part of the antibody and hence the C2 activated at a distance from the cell-bound C4. C2 is rapidly inactivated in serum and in these conditions is likely to be able to interact only with C4 molecules bound on the antibody molecule carrying the C1, or with immediately neighbouring C4 molecules. This could also explain why C4 bound to antibody aggregates is so much more effective than C4 bound to antibody-coated cells.

The activation of C2 is also very inefficient, but quantitative data on the number of activated molecules able to bind and form C42 complexes have not been obtained. A speculative scheme of the assembly of the early components is shown in Fig. 4 and illustrates the binding of C1q to the C_H2 domain of the antibody. The C1r₂-Ca²⁺-C1s₂ complex binds to the collagen tails of C1q and becomes activated⁷⁷. C4 and C2 in solution are activated by C1 and some of the C4 molecules bind either to antibody

Fig. 4 Suggested assembly of the early components of the classical pathway of complement on antibody bound to a cell surface. The heads of the C1q molecule bind to the C_H2 domain of the antibody and the C1r₂-Ca²⁺-C1s₂ complex to the collagenous tails of C1q through C1r. The activated C1s formed splits C4 and C2. Most C4 and C2 is inactivated in the serum but some C4 binds either to the Fab part of the antibody or to the cell surface. C2 binds to adjacent C4 molecules and forms C3 convertase, but is inactivated before reaching more distant C4 molecules which are ineffective in the haemolytic sequence.

molecules or to the cell surface. C2 molecules which are inactivated rapidly form a C42 complex only with C4 close to the bound C1 complex. The evidence that C4 binds to the Fab portion of the antibody is qualitative⁷⁸ or indirect⁷⁴ and hence is only tentative.

The C3 is split by the C42, and some associates to give C423 which changes its specificity from C3 activation to C5 activation⁷⁹; this is the last proteolytic step in the activation of complement. The activated C5 interacts with C6, C7, C8 and C9 to give the complex responsible for cell lysis and there is evidence that this can bind and lyse cells other than those coated with antibody and responsible for the early activation steps^{80,81}.

Mechanism of activation of the first component of complement

Of the biochemistry of the activation sequence certain mechanisms are clear. For example, in C1 bound or in solution, it is C1s which splits C4 and C2. C1q has no known catalytic activity and no covalent bonds are broken or formed when it interacts with aggregated antibody. C1r will not hydrolyse C4 or C2 in solution nor when bound to antibody aggregates as part of the C1 complex.

Similarly, C1s is not autoactivated when bound or in solution, but it is activated by C1r. It is not clear how C1r is activated²³. Although it is difficult to prepare C1r which is entirely stable at 37°C and neutral pH, repeated addition of proteolytic inhibitors such as diisopropyl fluorophosphate (iPr₂P-F) makes possible the isolation of preparations which are stable over several hours in these conditions. Activation of C1r when bound as C1 onto

Fig. 5 When the tetrameric complex C1r₂-Ca²⁺-C1s₂ interacts with C1q bound to aggregated antibody, the conformation of C1r is changed, exposing a proteolytic site (C1r^{*}). It is this site in the unsplit peptide chain which catalyzes the hydrolysis of a peptide bond and the conversion of C1r^{*} to C1r. C1r activates C1s to C1s^{*}. The active site of C1r^{*} is distinguished from that of C1r in that it reacts reversibly not irreversibly with nitrophenyl guanidine benzoate (NPGb) and it is not inhibited by diisopropyl phosphite fluoridate (DFP).

antibody aggregates occurs in 5–10 min, so satisfactory controls can be obtained³¹. It is then found that although C1q and C1r will bind firmly to antibody aggregates in the presence of Ca²⁺, no activation occurs. C1s in the complex is essential for C1r activation but C1r or C1s inactivated with iPr₂P-F (iPr₂P-C1s) can replace C1s. As iPr₂P-C1s is effective in facilitating the activation of C1r, C1s can have no proteolytic role in the activation. Presumably, therefore the binding of the C1r₂-Ca²⁺-C1s₂ complex is necessary because it determines the conformation of C1r. In the presence of 10 mM iPr₂P-F, C1r is still activated but C1s is not. As both C1r and C1s are inactivated readily by iPr₂P-F this agrees with the evidence that C1r activates C1s but suggests that C1r will not activate C1r in the complex, as is found in solution³¹.

Activation of C1r and C1s in the complex is inhibited if 1 mM nitrophenyl-guanidino-benzoate is present, but the inhibition is reversed on removal of this compound. Nitrophenyl-guanidino-benzoate will inhibit C1r and C1s irreversibly and hence again it is unlikely that C1r activates C1r (ref. 31). However, the kinetics of C1r activation show a sigmoidal curve suggesting autocatalysis. The most likely explanation of these results (Fig. 5) is that the binding of C1r₂-Ca²⁺-C1s to the C1q on the antibody causes the C1r to take up a conformation which exposes a catalytic site in the unsplit C1r molecule³¹. This catalyses hydrolysis of C1r to C1r which in turn activates C1s.

Activation of components C4, C2, C3 and C5

C1s then hydrolyses C4 with loss of a 6,000 molecular weight peptide chain from the α chain and also splits the C2 peptide chain into 70,000 (C2a) and 30,000 (C2b) molecular weight chains³². The activated C4 binds either to the Fab portion of the antibody or to the cell surface and interacts with such activated C2 molecules as reach it before they are inactivated. Inactivation of C2 seems to be continuous in terms both of loss of ability to form C42 and in loss of C3 convertase activity after formation. When C2 interacts with C4 covalently attached to Sepharose and is then treated with C1s, the 70,000 molecular weight fraction, C2a, dissociates leaving C2b still bound. It has been suggested that the interaction with C4 is through the C2b part of the molecule and loss (50% in 10 min) of C3 convertase activity may be due to the dissociation of the C2a which probably contains the catalytic site, from the complex⁶⁰. Characterisation of the catalytic site and explanation as to how interaction with C4 determines its specificity will be necessary for an understanding of the mechanism of these reactions.

The subsequent step of the formation of C5 convertase by interaction of activated C3 with C42 to give C423 is even less well understood, but investigation was made possible by the finding that treatment of human C2 with weak iodine solution produced a 10–20-fold increase in its stability and activity in forming C3 convertase⁶³. Centrifugation in a sucrose density gradient of C42 using iodine-treated C2 and C3 showed the presence of two peaks of C5 convertase activity of 14–16 S and 9–10 S and a peak of C3 convertase activity at 11.3 S (ref. 84). It was suggested that the heavy C5 convertase activity could be explained by the presence of an equimolar C423 complex and the lighter by an overlap of the C42 and C3 peaks. If this is correct, noncovalent binding of C42 and C3 is not essential for C5 convertase activity, but much more detailed investigation will be necessary to establish the nature of this enzymatically active complex.

This is the last proteolytic step in complement activation and no catalytic activity has been found in activated C5 or in the lytic complex it forms with C6, C7, C8 and C9. Of the four proteases of the classical system, C1r, C1s, C42 and C423, the first two are clearly of the serine esterase type and the two enzyme complexes, where the catalytic site is believed to be in C2, may also be of this type. However, it is unusual in that it is relatively resistant to diisopropyl fluorophosphate and, more surprisingly, the active site seems to be in the 70,000 molecular weight chain⁶³, whereas in all other serine esterase type proteases it is in chains of 20,000–30,000 molecular weight. All these proteases

of the classical pathway are active in solution but are probably bound to antibody or cell surfaces *in vivo*. This is likely to be an essential feature, as plasma and other body fluids contain high concentrations of proteolytic inhibitors and activation must depend on the local excess of protease over inhibitors.

There are many finely balanced features of this highly complex system, the ramifications of which are far from clear, and the unravelling of the mechanisms of activation and control seem likely to throw new light on an animal's immune defence against infection.

High energy neutrino astronomy

David Eichler & David N. Schramm

Enrico Fermi Institute, University of Chicago, Chicago, Illinois 60637

The possibility of doing point source neutrino astronomy is discussed. Probable sources include galactic nuclei, Seyferts, quasars, radio galaxies, pulsars and supernovae.

THE possibility of building a very large deep underwater muon and neutrino detector (DUMAND)¹, which would look at the interactions of neutrinos produced by cosmic rays hitting the atmosphere has been discussed. New design ideas mean that this detector may be able to resolve the direction of origin of the neutrinos to better than 1 deg² which opens up enormous possibilities for point source neutrino astronomy some of which are considered here. These may not need to wait for DUMAND but may be realisable with existing detectors of the type being developed by Lande². For most of our discussion, however, we will use proposed parameters for DUMAND; such that a flux from a point source of order 10² eV cm⁻² s in neutrinos more energetic than 3 × 10¹¹ eV constitutes a detectable signal for a 10⁹ ton detector in one year of viewing time. (This flux produces 10 counts per yr per 10⁹ tons.) Signals as small as 10 eV s⁻¹ cm⁻² may prove to be detectable due to solid angle resolution and proper identification of background and effective detector masses larger than 10⁹ tons. The 10⁻² eV flux level is not large by astrophysical standards: the brightest non-thermal sources (such as pulsars and active galactic nuclei) have fluxes far greater than this, so if they can somehow put even a small fraction of their total luminosity in the form of high energy neutrinos, they are in principle detectable.

Any system which has high energy proton collisions will produce neutrinos due to pion and kaon production and decay in such collisions.

The production of high energy neutrinos in astrophysical systems thus entails first the production of high energy protons, followed by their degradation through pion and kaon producing collisions against other protons^{3,4}. The most important astrophysical reaction is

While the neutral mesons decay into γ rays, the charged pions eventually decay into three neutrinos and an electron (or positron) by the standard decay sequences. The cross section for proton collisions is roughly 40 mb, and is only weakly dependent on the collision. Thus protons are stopped over a path length of about 30 g cm⁻². The leading pion may contain a significant fraction of the collision energy, thus a few neutrinos may carry away a large fraction of the collision energy⁵.

Pions can also be produced in proton-photon collisions when the photon has an energy >600 MeV in the frame of the proton.

The cross section for this reaction depends on the collision energy and at maximum is

$$\sigma_{\pi\pi} \approx 2 \times 10^{-28} \text{ cm}^2 \quad (2)$$

Diffuse sources

High energy galactic cosmic rays hitting the upper atmosphere will produce high energy neutrinos. These are the prime neutrinos which the high energy physicist might use for directly probing the nature of the weak interaction, and searching for intermediate vector bosons and Higgs particles. This diffuse atmospheric flux will be higher for those neutrinos coming from the horizon than from overhead due to the relative (atmospheric) decay length. In addition, at high energies this flux will drop off with energy by an additional 1/E due to time dilation on the decay of the π 's and k 's preventing neutrino production. The average intensity of this background in the energy range of interest, 10¹²–10¹⁴ eV, is <0.3 counts deg⁻² yr⁻¹. These considerations indicate that this atmospheric background should be easily distinguished from neutrino fluxes of extraterrestrial origin. (Direct neutrino production⁶ will not have the additional 1/E drop off but it is down $\sim 10^{-4}$ relative to π and k production.)

Berezinsky and Zatsepin⁴ and Margolis *et al.*⁴ have noted that the galactic cosmic rays interacting with the interstellar matter will produce a background which is marginally detectable and is peaked towards the galactic centre. Here, as in all astrophysical sources, all of the π 's and k 's decay so the ν -spectral index is essentially the same as that of the high energy protons with no additional 1/E time dilation effect.

Other galaxies will similarly contribute to the diffuse ν -background^{3,4}; however, if the other galaxies have the same galactic cosmic ray intensity and spectral shape as ours, then ours will dominate the diffuse ν -background. On the other hand, it is reasonable to expect that galaxies were more energetic in the past and thus produced more ν 's. Berezinsky and Zatsepin⁴ mentioned the possibility of a very early 'bright phase' of galaxies to produce very large numbers of ν 's. These ν 's will, of course, be redshifted, but they may, nevertheless, dominate the diffuse background. Thus, a measurement of the diffuse background alone would enable us to make some discrimination between a bright early phase for galaxies and the situation where early galaxies are similar to our present one.

Point sources

For the astronomer, the most appealing aspect of a large neutrino detector, such as DUMAND, is the ability to resolve

individual point sources. As mentioned earlier, a variety of non-thermal systems would be detectable if they generate a significant fraction of their luminosity in high energy neutrinos. To do so, a system must, (1) produce fast particles efficiently; and, (2) contain enough target matter near the source of the fast protons to stop a significant fraction of them. Many of the most exciting objects in the sky may meet these criteria. Table 1 lists several astrophysical situations in which both these conditions may be met.

Supernovae

Standard cosmic ray models assume that a typical supernova puts out 6×10^{50} erg in relativistic cosmic rays. With the spectrum proportional to $E^{-2.5}$. The neutrino counting rate in a 10^9 ton detector is then⁶

$$R = 10^{-3} n / D^2 \text{ d}^{-1} \quad (3)$$

where D is the distance in kpc to the supernova remnant and n is the ambient density in atoms cm^{-3} of the medium in which the remnant is situated. Regardless of the detailed mechanism by which the cosmic rays are accelerated in either the remnant or the shock itself, the basic fact remains that if the supernova occurs in a dense cloud where η may be as large as 10^3 , it would then be a detectable point source of high energy neutrinos. Because supernovae are presumably rapidly evolving massive stars, it is reasonable to assume that many go off while still in the immediate vicinity of the cloud out of which the presupernova star formed. It is also likely that a presupernova star will undergo significant mass loss and hence create its own circumstellar cloud.

A supernova in a dense environment would also be detectable by γ -ray satellites in the energy range $E_\gamma < 1$ GeV. Indeed, coincidences have been reported⁷ between unidentified γ -ray sources detected by the Cos B satellite and radio emitting supernova remnants. The signal detected by Cos B, if assumed to be the low energy end of an $E_\gamma^{-2.5}$ γ -ray spectrum originating from π_0 decay, would yield 10 – 10^2 $\text{eV cm}^{-2} \text{ s}^{-1}$ in 10^{12} eV γ -rays, and a comparable flux in high energy neutrinos.

Pulsars

Pulsars accelerate high energy protons⁹ which if they hit something will produce neutrinos. Berezhinsky⁸ has pointed out that young pulsars, blanketed by a supernova remnant less than a year old could be bright sources of high energy neutrinos. However, their behaviour at such early times is highly uncertain. Despite these uncertainties, it is reasonable to believe that a pulsar in a binary system could be a source of high energy neutrinos for the first few thousand years of its existence¹⁰. The stellar wind of the companion could have a column density as high as 1 – 10 g cm^{-2} , its corona could provide further target material and an accretion cloud could conceivably surround the pulsar. If the companion is a red giant, its envelope could block

nearly half the high energy protons emitted by the pulsar. A pulsar emitting (roughly the luminosity of the Crab pulsar) $10^{37} \text{ erg s}^{-1}$ in high energy particles ($E_p > 10^{13}$ eV) at a distance of D kpc produces

$$R = \eta D^{-2} 10^2 \text{ counts d}^{-1} \quad (4)$$

where η is the fraction of the luminosity converted to high energy neutrinos by the target material near the pulsar. A typical value of η might be between 10^{-3} and ~ 1 .

Helfand and Tademaru¹¹ have speculated, on observational grounds, that a significant fraction of all pulsars form in binaries. Stepnian *et al.*¹² have detected a flux in high energy γ rays ($E_\gamma > 3 \times 10^{12}$ eV) of about $60 \text{ eV cm}^{-2} \text{ s}^{-1}$ from Cyg X3, which is generally held to be a (heavily blanketed) pulsar in a binary system. A comparable flux in high energy neutrinos would be detectable with a 10^9 ton detector in a year or two of viewing time. Any process—such as Colgate's¹³ shock mechanism—which produces high energy particles promptly during the initial supernova explosion will produce a prompt burst of neutrinos if the exploding star has a binary companion. For example, in the type I supernova model where a white dwarf accretes beyond the Chandrasekhar limit from a red giant companion, the explosion will, of course, occur in the vicinity of that companion. The narrow pulse detected at Earth would contain a maximum of

$$N = \eta 10^8 D^{-2} (U/10^{48} \text{ erg}) \text{ counts}$$

where U is the energy output of relativistic particles, and η is the fraction of them stopped by the binary companion and surrounding material. A typical value here for η might be as high as 0.5.

Galactic nuclei

The most potent sources of high energy neutrinos may be active galactic nuclei¹⁴, such as those of radio galaxies, Seyferts and possibly quasars. Such nuclei are capable of luminosities as high as 10^{43} – $10^{47} \text{ erg s}^{-1}$. As the radiation seems to be of non-thermal origin, it is believed that the power outputs in high energy particles take on similar values. As these high energy particles would be produced within the innermost regions of the nucleus, which have column densities well in excess of a typical galactic disk, the high energy protons produced there might be expected to be stopped by nuclear collisions before escaping the nucleus. (Consider, for example, that cosmic rays in our own galactic disk go through a few g cm^{-2} of matter before escaping. Were the column density of the disk a factor of 30 higher, the dominant loss mechanism would be nuclear collisions.) Moreover, it can be argued¹⁵ that the accretion column surrounding a collapsed object in the nucleus may have column densities of 10^2 – 10^3 g cm^{-2} , which would be sufficient to even stop the γ rays, but the ν 's would still easily escape.

Thus, one could reasonably expect that such active nuclei put out a significant fraction ($\geq 10\%$) of their entire luminosity in the form of high energy neutrinos. The nearby peculiar galaxy M82 (often thought to be an exploding galaxy because of its optical appearance) could give a neutrino count rate in excess of 1 per day if, indeed, there are nonthermal processes occurring in its nucleus. Other nearby active nuclei, such as Cen A and M87 could give count rates of the order 10 per year. Grindlay *et al.*¹⁵ reported a high energy ($E_\gamma > 3 \times 10^{11}$ eV) γ -ray flux of the order of $50 \text{ eV cm}^{-2} \text{ s}^{-1}$ from Cen A. A comparable flux in high energy neutrinos would be detectable within a year of viewing time. (Remember that the atmospheric background per deg in a 10^9 ton detector is $\leq 0.5 \text{ counts yr}^{-1}$ thus as few as 3 counts yr^{-1} from the same deg would indicate a point source.)

Compact radio sources emit in bursts which almost certainly originate within regions smaller than a light day. Thus, a few years worth of neutrinos as computed from average luminosities could arrive within a few hours, making them much more easy to detect. It has been suggested¹⁶ that as many as 10^4 counts per 10^9 tons per burst could be recorded from a radio burst, for example, the nucleus of 3C120.

Table 1 Possible high energy neutrino sources

Site of He Particle production	Target material	Maximum expected counting rate from a typical source
Expanding supernova remnants	Ejecta, swept up matter, dense cloud from which star formed	10^2 per yr per 10^9 tons
Stellar explosions	Binary companion	$10^8/10^9$ tons per event
Pulsars	Binary companion, accreting matter young supernova remnant	10^3 per yr per 10^9 tons
Seyferts, radio galaxies, and QSOs	Clouds in nucleus, matter accreting on to compact object	10^3 per yr per 10^9 tons

Particularly significant is the fact that $\sim 10\%$ of the flux from Cen A is in the form of high energy γ rays. This corroborates the picture sketched above, that is that a significant fraction of the luminosity of a non-thermal galactic nucleus is caused by very energetic particles. The energy density in the Universe due to emission by Seyferts and QSOs has been conservatively estimated at $10^{-3} \text{ eV cm}^{-3}$. If Seyferts do emit $\sim 10\%$ of their luminosity in the form of high energy neutrinos, the energy density in such neutrinos could be as high as $10^{-4} \text{ eV cm}^{-3}$. Thus, one could reasonably hope to discover a cosmic background of high energy neutrinos standing out above the atmosphere at $E_\nu > 10^{12} \text{ eV}$.

Limits on deuterium production

Another area where neutrino astronomy may be critical is in constraining the astrophysical locations for producing deuterium¹⁷. If deuterium is only produced cosmologically then the Universe is open (see ref. 18 and refs therein). Epstein *et al.*¹⁹ showed that the only allowable alternative to the big bang for producing deuterium was extremely high energy particle interactions where most nuclei (in particular Li, Be and B) would be broken down to free nucleons. To avoid seeing the simultaneously produced γ 's from such interactions, any such production site must be hidden in an optically thick region (for example, Epstein²⁰ proposed the centres at quasars), however, neutrinos cannot be hidden in this way. Thus, limits on the neutrino flux would constrain, if not eliminate, any non big bang deuterium production site. The Reines experiment²¹ implies that the cosmic background at $E_\nu < 10^{12} \text{ eV}$ is well below the atmospheric background, and it can be shown²² that this constrains Epstein's model for deuterium production to $1 + Z > 2000(A^2\Omega)^{-2/3}$.

Conclusions

Many of the most exciting objects in the sky may be high energy neutrino emitters. Any object that emits γ 's by π^0 production will also naturally be a neutrino source. Thus, γ -ray astronomy gives us some degree of confidence that neutrino astronomy will not be a null field. However, the two fields are complimentary and will not merely duplicate each other because neutrinos are capable of being seen even when they are produced in regions which are optically thick to γ rays. For example, the very compact central regions of active galaxies, with their intense radiation fields, will be optically thick to γ -rays but can be

studied by neutrino astronomy. In probing these very central regions, one may discover how these objects are powered. In fact, even a null result is interesting because it would indicate the degree to which high energy particles are involved. In addition, γ -ray detectors mostly tend to be sensitive to lower energies, thus seeing an object in both ν 's and γ 's will tell us a lot about its high energy particle spectrum. (The mean free path of γ 's of energy $\geq 10^{14} \text{ erg}$ is $\approx 10^4 \text{ kpc}$).

One final advantage of ν -detectors is that they simultaneously observe a full 4π steradians. Thus they will not miss transient point sources. This feature may enable ν -detectors to alert other branches of astronomy to transient objects.

Whenever astronomers have opened a new channel for studying the Universe, new and unexpected sources have been discovered. One only has to consider, quasars and pulsars from radio astronomy, Cyg X1 from X-rays, and the still mysterious X-ray and γ -ray bursters to realise that the most exciting possible discoveries from ν -astronomy may not have been mentioned here.

We thank Fred Reines, Art Roberts, Maury Shapiro, Rein Silberberg, Steve Margolis, Ken Lande, John Learned, Ben Berezhinsky, and John Scott, and many others for stimulating discussions and suggestions. This work was supported in part by the NSF at the University of Chicago.

The distribution of the Tertiary and Lower-Upper Cretaceous sediments in part of the northern continental margin of the Bay of Biscay, has been mapped. Three sedimentary sequences are indicated by the seismic profiles.

THE part of the northern continental margin of the Bay of Biscay discussed here intersects and lies seawards of the rifted Mesozoic-Cainozoic basin and Cornubian granite platform of the western approaches to the English Channel. The continental

slope is broad and marked by prominent features such as the Meriadzek Terrace, Trevelyan Escarpment and the Goban Spur. The structure of the margin consists of thin and unfaulted, Tertiary and Lower-Upper Cretaceous sediments that mantle a series of tilted and rotated fault blocks¹ underlain by a thinned continental crust^{2,3}. The distribution of these sediments and the fault blocks has been mapped using 10,000 km of multichannel seismic profiles occupied by the Institut Français du Pétrole (IFP-CNEXO-CEPM) and the Institute of Oceanographic Sciences for the Department of Energy (UK). These data were

acquired using 24-channel common depth point reflection techniques and processed using deconvolution before and after stack followed by the application of time and space variant filtering. Diffraction migration has also been applied to clarify reflections.

The seismic profiles show that the tilted and rotated blocks are bounded by lystric faults which delineate half-grabens created during rifting and subsequently covered by post-rift sediments^{1,4}. Three sedimentary sequences can be recognised on the seismic profiles. A pre-rift series which consists of thick layered sediments shown by parallel inclined reflectors is clearly visible within the fault blocks. Evidence for the age and depositional environment is given by drill and dredge data⁴⁻⁷. Site 401 of DSDP Leg 48 (refs 4, 5) penetrated Kimmeridgian-Portlandian limestones in the crest of one fault block although the regularity of the pre-rift reflectors (Fig. 2a) hints that substantial facies changes may be present. Dredging on exposed fault blocks at 4,200 m depth near Goban Spur, however, has yielded granites of Hercynian age⁷ and pebbles of Permo-Triassic (?) sandstones have been noted in Lower Cretaceous conglomerates⁶. The second syn-rift sequence, deposited contemporaneously in the half-grabens, is inferred to be pre-Aptian and probably post-late Jurassic⁴. The post-rift sequence penetrated at DSDP sites 400A, 401 and 402A was deposited after the end of rifting and the onset of spreading in Aptian time. It comprises thin pelagic or hemipelagic sediments of post-Aptian age that drape the underlying fault block topography⁴.

The tilted and rotated fault blocks can be followed from the shelf break to the outer part of the rise in the vicinity of the Trevelyan Escarpment at 4,500 m depth. The polarity of the faulting is consistently down towards the continent-ocean boundary and true horsts are rare. The fault blocks (Figs 1, 2a) typically trend WNW-ESE subparallel to the margin but their continuity is limited due to normal faults whose NE-SW and E-W trends may reflect the influence of older Hercynian structures such as the Armorican shear zones. Towards the Goban Spur, the fault blocks change trend to NNW-SSE and are paralleled by the magnetic anomalies of the adjacent ocean crust⁸. In both areas, the position of the continent-ocean boundary (Fig. 1) is clearly shown by a sharp change to a strongly diffracting opaque reflector that contrasts with the tilted reflectors observed within the fault blocks.

The fault blocks are typically spaced at between 10 and 30 km (Figs 1, 2a) and the bounding fault planes curve and flatten with depth. Throws of individual faults may be as much as 3-4 km. Comparable lystric faults have been described from the Viking Graben of the North Sea^{8,9} and from the Gulf of Suez rift¹⁰. Beneath the irregular surface defined by the crests of the fault blocks, a prominent reflector 'S' (Fig. 2b) is observed at depths between 9.0 and 11.0 s beneath the rise. Variations in the travel time to reflector 'S' beneath and between the fault blocks are produced by lateral variations in velocity. It may therefore be assumed that reflector 'S' is sub-horizontal and thus independent of the overlying faulted layer. Indeed, we have not observed any displacement of reflector 'S' even though the curved normal faults are associated with throws of as much as 3-4 km. An exactly similar feature observed at the western foot of Galicia Bank to the west of Portugal shows that reflector 'S' is not a local phenomenon (Fig. 4).

Further evidence on the nature of reflector 'S' is given by a refraction profile which crosses our seismic reflection profiles and was obtained by CNEXO using OBS (ref. 2). The base of the 4.9 km s⁻¹ layer is 9.5 km, close to the depth at which the lystric faults become horizontal. Below this layer, a 3-km thick layer with 6.3 km s⁻¹ occurs above the Moho (8.2 km s⁻¹). The refraction data indicate that the interface between the 4.9 and 6.3 km s⁻¹ layers lies at ~9.2 s, in reasonable agreement with the observed depth of reflector 'S' (Figs 2b, 3). The structure of the faulted layer is, however, complex, and horizontal inhomogeneities may be present. In view of this and the small 3-km thickness of the 6.3 km s⁻¹ layer the possibility exists that reflector 'S' may be the Moho. Clearly, further seismic studies are necessary.

Rifting and crustal attenuation

Experimental simulation of rifting using clay models has clearly shown that normally faulted tilted blocks are formed in response to crustal tension¹¹. The accommodation of these movements at depth bears directly on proposed mechanisms of crustal attenuation during rifting. One widely used model of rifting is based on analogues such as the East African rift system or Rhine graben.

Fig. 2 *a* Tilted block and lystric fault. Acoustical basement B is constituted in a great part of layered sedimentary rocks of probable Jurassic and early Mesozoic age. These formerly continuous layers were faulted and tilted during the early Cretaceous rifting phase. Vertical scale in seconds, two-way travel time. Numbers 1a, 1b, 2, 3, 4 refer to overlying sedimentary formations: Profile OC 412, migrated; Site 400. *b*, Geological cross section through site 400 with same horizontal and vertical scale, constructed from seismic reflection—profile OC 412 migrated (see Fig. 1). Note the lystric faults bounding the tilted blocks. Near base of lystric faults is an horizontal reflector corresponding to interface between 4.9 km s^{-1} and 6.3 km s^{-1} layers defined by seismic refraction data. Moho discontinuity is at 12 km (ref. 24).

The following stages have been proposed¹²: upwarping or doming of the crust, incipient volcanic activity, formation of faults and increasing volcanic activity, subsidence of the graben(s). Other workers^{13,14} proposed that domal uplifts developed in isostatic response to mass deficiencies produced by partial melting of the mantle above rising plumes at the base of the lithosphere. In these models, sub-aerial uplift and erosion with 'sub-crustal erosion' are offered as a means of thinning the crust. The second and fundamentally different mechanism pro-

poses a combination of extension by brittle fracture in the upper part of the crust and ductile flow in the lower part of the crust¹⁵⁻¹⁹. Important constraints can be placed on these by the regional geology of the margin and also by the geometry of the extensional fault fabric.

In the Bay of Biscay, sub-aerial uplift which preceded rifting is not evident, in contrast to the classical models⁴. Rifting, which probably took place between late Jurassic and Intra-Aptian time⁴ occurred in a pre-existing epicontinental sedimentary

basin of Mesozoic age perhaps first formed during earlier Permo-Triassic distension^{5,9}. The seismic profiles indicate that no erosion occurred before and during rifting on the outer part of the margin, that is, in the axis of the rift system. Dredge data^{6,7}, the drilling results from Leg 48 (refs 4, 6) and the seismic data indicate that at the end of rifting, water depths were of the order of 2,000 m in the outer part of the margin. The existence of deep water marine beds implies that rifting was not associated with a substantial sub-aerial relief—a conclusion that can also be drawn for the Parentis Basin in south-east Biscay²⁰. We suggest that the rifting was not preceded by and is thus not a consequence of a domal uplift. Beneath the inner part of the margin, however, the crests of some tilted blocks are cut by a horizontal plane, indicating that some sub-aerial erosion did take place when the fault blocks were rotating.

The importance of normal faulting in thinning the crust has been more contentious, for little has been known of the geometry of such faults at depth and their relationship to the deeper structure of passive margins. The new data (Figs 2b, 5) clearly show that the lystric faults do not continue as far as the base of the crust but curve and flatten with depth demonstrating that extensional faulting is confined to the upper part of the crust. Such faults are considered to form by simultaneous faulting and tilting so that the fault blocks rotate towards the central subsiding trough and individual blocks dip away from the rift

if high pore fluid pressures are absent²², it seems unlikely that these would develop under an extensional stress regime.

Our hypothesis considers that the termination of faults with depth marks a fundamental transition in the rheological properties of the crust from brittle above to ductile below^{19,23,24}. The boundary or transition between them may be marked by the deep reflector 'S' so that the interval between the lystric faults and the Moho corresponds to a zone of ductile flow characteristic of the lower part of the crust. The hypothesis implies that there is a depth in a homogeneous crust subject to extension below which ductile behaviour occurs and above which elastic strain is released by periodic faulting. Flow within the ductile layer during rifting, that is, while the continental crust remains joined, is considered to accommodate the balance of the thinning required by the geological and geophysical data.

Our observations of rift tectonics in the Bay of Biscay support modifications to the Vening Meinesz hypothesis of rift valley formation made by various authors^{15-17,21,23-25}. Intraplate stresses arising from continental collisions or from small differences between the absolute velocities of plates may initiate stretching of the lithosphere^{10,14}. These stresses are imposed on a crust consisting of the brittle upper layer and a lower ductile layer that can deform rapidly when stress differences are large. As shown above, the limited extension and thinning produced by brittle fracture compared to the more important ductile thinning of the

Fig. 3 Seismic profile south of Goban Spur showing tilted blocks with lystric faults. Note the horizontal reflector S below the tilted blocks. It is observed on the deepest part of the margin. On Trevelyan it corresponds to the boundary between a 4.9 km s^{-1} layer and a 6.3 km s^{-1} layer only 3 km thick. The Moho is around 12.5 km below sea level. Profile CM 16, processed.

axis²¹. Beneath the outer part of the margin, the continental crust affected by lystric faults is $\sim 6 \text{ km}$ thick although rotation of the blocks reduces this thickness to about 4–5 km (Figs 2b, 5).

As further fault movement becomes difficult when the fault plane becomes horizontal, we have roughly compared the crustal thinning and extension derived from the variable fault geometry with that given by gravity models and refraction data^{2,3}. For the typical rotation of $20\text{--}30^\circ$, extension of the area between the present shelf edge and the continent-ocean boundary is $\sim 10\%$ of the previous width. The rotation data also indicate a thinning of between 6 and 9 km (after ref. 21). The refraction data show, however, that the crust has thinned to 6 km (that is by 24 km assuming an original thickness of 30 km) beneath the outer part of the margin^{4,5}. We therefore conclude that extensional faulting in the upper part of the crust during rifting is inadequate to account for the observed thinning.

Clearly, the lower part of the crust must also be thinned but by some other mechanism. We have considered an origin by decollement, although this is not preferred, as both gravity and high frictional drag must be overcome to allow movement along a subhorizontal zone dipping toward the continent. Furthermore, the direction of movement would be opposite to that taking place during extension. Although frictional drag can be reduced

lower crust suggests decoupling between the brittle and ductile parts of the crust. Experiments in rock mechanics³⁰ have shown that the strain of ductile material increases continuously once a certain level of stress is reached (viscous behaviour). In contrast, continuous strain in the brittle material is limited because stress increases only until released by fracturing. These differences in rheological behaviour may imply that thinning of the ductile part of the crust began before the creation of the first fault in the brittle crust. As tensile stresses are the same at the lateral boundaries of the lithosphere, it follows that extension by continuous viscous flow initiated by a lower level of stress in the lower ductile part is more important than in the upper, brittle part. Normal faults develop as the strength of the brittle layer is exceeded and downfaulting results in a decrease in tensile stress and elastic shortening that equals the extension caused by faulting. Continued viscous flow in the ductile layer results in the accumulation of stress in the brittle layer that is relaxed by further faulting. The continuous necking of the lower ductile part of the crust is accompanied by a rise of the mantle and a development of a depression, the rift, in the brittle upper crust that allows continued rotation of the fault blocks along the lystric faults. It is important to realise that the mechanism allows greater thinning within the ductile layer than in the brittle layer

SDT W

E SDT

Fig. 4 Seismic reflection profile immediately west of Galicia Bank showing tilted blocks and lytric faults and an horizontal reflector below, as on Fig. 1(7); seismic formations 1-4 are the same as defined in Northern Biscay. Profile IFP-CNEXO-CEPM GP12 processed.

because of the difference in rheological properties. Extension within the brittle layer should not be regarded as a measure of thinning which largely takes place within the ductile layer.

Models suggested for the Baikal rift and Rhine Graben^{15,16} fit our observations well. Heat flow data for the Biscay margin²⁷ can only be interpreted in terms of thinning of the ductile lower part of the continental crust and not in terms of phase changes or intrusions. Rim uplifts predicted by the model may be due to regional isostatic adjustment indicated by the erosion of the fault blocks observed near sites 401 and 402 and more widely on the shelf. In Biscay, Galicia and the Aquitaine Basin^{1,4,20,26}, the regional geological data indicate that the rifting took place in a pre-existing epicontinental basin subject to subsidence and perhaps weakened during earlier rifting episodes. In these cases, previous crustal thinning which may have occurred in response to sediment loading as well as rifting may have subdued the development of complementary uplifts or erosion may have kept pace with uplift. The faulting may have been rapid although we cannot be specific on this point. For example, onlap of reflectors within the bedded sequence contained within the fault blocks is rare but thickening towards the axes of the half graben is common. This observation is indicative of relatively rapid and continuous contemporaneous movement rather than episodic movement.

Post-rifting subsidence

Regional subsidence of passive margins beginning at the onset of spreading and after rifting is a widely recognised phenomenon. In Biscay, post-rift subsidence of 2,300 m indicated by shallow water Aptian-Albian sediments was comparable to the subsidence produced by rifting^{4,5}. This subsidence was not caused by faulting, for the post-rift sediments are only rarely affected by faults. These exceptions are faults of late Eocene age developed along the Trevelyan Escarpment in response to the Pyrenean compression. The post-rift subsidence therefore took place by oceanwards tilting of the margin without decoupling of the continental and oceanic crust. Subsidence due to loading can be

neglected in Biscay as the post-rift sediments are thin (Figs 2b, 5).

The most widely accepted mechanism of post-rift subsidence is thermal contraction of the lithosphere initiated as the heat source migrates away from the margin at the onset of spreading; the exponential decrease in subsidence with time is considered to be similar to that deduced for the ocean crust^{4,28}. The depth of deposition of Aptian sediments (Fig. 6) that is, of the topography of the margin at the end of rifting, has been reconstructed from the new seismic and palaeobathymetric data⁴. Although the present altitude of a point on the margin depends on its initial altitude, the curve shows that the subsidence increases progressively from the shelf towards the deep ocean. Variations in

Fig. 6 Absolute amount of post-rifting subsidence of N. Biscay margin from the shelf to the oceanic crust. Upper dotted line, simplified topography of the rift at Aptian time; lower dotted line, present depth of Aptian corrected for loading; solid line, amount of subsidence.

subsidence rate cannot be defined with precision, however, because palaeontologically determined depths become increasingly inaccurate for increasing water depths and age. Nevertheless, data⁴ do not contradict an exponential decrease in subsidence. The subsidence of the thinned continental crust adjacent to the continent-ocean boundary is greatest and most similar to the ocean crust, whereas that of the thick crust beneath the shelf is least and most different. The magnitude of the subsidence is thus clearly related to crustal thickness. Change of slope on the subsidence against distance curve at 150 km (Fig. 6) may reflect abrupt changes in crustal thickness. The curve also substantiates the coupling of the continental and oceanic crust because subsidence of the oceanic crust is approximately equal to the continental oceanic crust.

Unfortunately, we cannot address the role of the ductile layer, Moho and Upper Mantle on the subsidence during and after rifting. Their nature and position may well have been different during and after rifting. Nonetheless, spatial variations in the post-rift subsidence of the passive margins of Biscay are at least a partial function of crustal attenuation produced by thinning of the ductile layer during rifting.

A new Thy-1 alloantigen as a temporal marker of T lymphocyte differentiation

D. B. Thomas, Raquel A. Calderon & Lynda J. Blaxland

National Institute for Medical Research, Mill Hill, London, NW7 UK

A new Thy-1 alloantigenic specificity is defined in the mouse. Antigen expression is restricted to 'mature' and memory T cells, with either helper or killer activity.

THE importance of lymphocyte differentiation antigens in defining the cellular heterogeneity of the immune system is now well established; functionally distinct lymphocyte populations exhibit a unique surface antigen phenotype, and may be enriched or depleted with specific antibody¹. In the mouse, the initial classification of lymphocytes as B or T cells was based on surface expression of immunoglobulin or the Thy-1 alloantigen^{2,3}. Subpopulations of T cells have since been defined. These are distinguished by their differential expression of the alloantigens Ly-1, Ly-2 and Ly-3 (refs 4–6). Studies by Cantor and Boyse with the Ly markers indicate two independent pathways for the differentiation of T lymphocytes^{7,8}: thymocytes and 'precursor' T cells with a Ly-1⁺ 2⁺ 3⁺ surface phenotype generate either helper cells (Ly-1⁺ 2⁺ 3⁺) or suppressor/killer cells (Ly-1⁺ 2⁺ 3⁺), commitment to either differentiation pathway preceding exposure to antigen. However, virgin and memory T lymphocytes cannot be distinguished by means of these markers.

Evidence is presented here for a new Thy-1 alloantigen which may be used to distinguish virgin and memory T cells. The antigen is absent from neonatal T cells but present on 50% of the adult T cell population. Functional tests indicate that this new specificity is restricted to 'mature' and memory T cells, with either helper or killer activity.

Xenoantisera to Thy-1

Experiments with xenoantisera to murine tissues provided the first, fortuitous indication that Thy-1 included an hitherto unrecognised specificity. Rats and AKR mice both express the Thy-1.1 alloantigen on brain and thymus, and reciprocal immunisation should only elicit antibody to xenogeneic determinants. It was unexpected to find that rat antiserum to AKR brain defined a subpopulation of T lymphocytes (Fig. 1).

Xenoantiserum dilutions of log₃ 1–3 and C' (guinea pig complement) lysed a constant number of cells in AKR thymus (75–80%), lymph node (30–35%) and spleen (18–20%),

without affecting bone marrow cells (<4%). (Values are also included in Fig. 1 for lysis by Thy-1.1 alloantibody and C'.) Cytotoxicity was removed by absorption with AKR brain, but not rat brain or thymus, thereby excluding autoantibody activity.

Identical values were obtained with lymphoid tissues of Thy-1.2-positive mice: CBA, C57BL/6, BALB/c, LPJ, C3H/he and A strains. However, spleen cells from outbred, athymic *nu/nu* mice were not lysed (<3%), suggesting specificity for a subpopulation of T lymphocytes (about 50% of Thy-1⁺ cells in spleen and lymph node, Fig. 1). This was confirmed in experiments with mitogen-treated cultures of CBA spleen. Xenoantiserum (1/3 to 1/9 dilution) and C' lysed concanavalin A-induced T lymphoblasts (35–50%) and phytohaemagglutinin A-induced T lymphoblasts (18–25%) but not lipopolysaccharide-induced B lymphoblasts (<4%) at the peak of the mitogenic response (48–72 h).

The number of peripheral lymphocytes lysed by xenoantiserum and C' showed a striking change with age. There was no appreciable lysis by xenoantiserum during the first 2 weeks of

Table 1 Indirect immunofluorescent staining of CBA spleen cells with xenoantibody or alloantibody after capping of surface immunoglobulin

	Fluorescent cells (% ring staining)
Anti-BAT	25
Anti-Thy-1.2	41
Anti-Thy-1.2 ab	22
FITC-anti-mouse IgG	4
FITC-anti-rat IgG	3

CBA spleen lymphocytes ($5-10 \times 10^7$; 3 ml) were incubated with fluorescein isothiocyanate (FITC)-conjugated rabbit anti-mouse IgG (Miles; 1/20 dilution) for 2 h at 37°C (minimum time for complete capping) and washed twice with buffered saline. Aliquots ($2-4 \times 10^6$; 100 μ l) were then incubated with an equal volume of anti-BAT (1/3–1/12 dilution) or anti-Thy-1.2 ab (1/10–1/30 dilution) or anti-Thy-1.2 (1/10–1/30 dilution) for 30 min at 3°C, washed and incubated for 30 min at 3°C with 50 μ l of FITC-conjugated rabbit anti-rat IgG or FITC-conjugated rabbit anti-mouse IgG. Cells were washed and examined with a Leitz Ortholux fluorescence microscope.

life (Fig. 2; <4%). Moreover, absorption of antiserum with newborn CBA spleen (1: 1, v/v; 2 h at 3 °C) did not alter the cytotoxic titre for adult spleen or lymph node, thus indicating absence of a particular cell population from the neonate. However, the adult number of T cells were lysed by Thy-1 alloantibody within a day of birth. Henceforth, the antigen(s) recognised by rat anti-AKR brain sera will be referred to as 'BAT' (brain-associated thymus antigen).

Effect of thymectomy

The neonatal mouse is immunologically incompetent and surgical removal of the thymus drastically, and permanently, impairs homograft immunity, whereas thymectomy at 3 weeks has little effect^{9,10}. However, the proportion of Thy-1⁺ cells in peripheral

Fig. 1 Cytotoxic titre of rat anti-AKR brain serum and C' for AKR lymphoid cells: thymus (●), lymph node (■), spleen (▲) and bone marrow (×). Values are also included for lysis of thymus (○), lymph node (□) and spleen (△) by anti-Thy-1.1 (1/16 dilution: Searle Diagnostic) and C'. Rats, either outbred Wistar or inbred PVG and August strains, received five weekly intraperitoneal injections of AKR brain homogenate (1:1, v/v; phosphate-buffered saline, PBS). Sera from 6–8 rats were pooled, heat-inactivated and absorbed with mouse liver homogenate to remove species antibody (1:1, v/v; 2 h at 3 °C). Viable lymphocytes (>98%) were obtained by Ficoll-Hypaque centrifugation of tissue cell suspensions. In the cytotoxic assay, equal volumes of cells (2.5×10^6 ; 50 μ l), xenoantiserum and C' (absorbed with Agarose) were incubated at 37 °C for 30 min and washed with PBS (2 ml). A two-step incubation was used for anti-Thy-1.1 to avoid the anti-C' activity of mouse serum. Cell viability was estimated by dye exclusion using eosin (0.1%, w/v). Control values for normal rat serum (absorbed with mouse liver) and C' were <4% dead cells.

lymphoid tissues is identical in the neonate and adult (ref. 11, Fig. 4a), perhaps indicating further, thymus-dependent, maturation of the peripheral T cell in the first 2 weeks of life.

The percentage of cells reacting with xenoantibody showed an abrupt increase during this time (Fig. 2). An attempt was made to determine whether thymectomy affected the appearance of the BAT⁺ cell population. CBA mice were thymectomised at 3 d or at 3 weeks, and killed at weekly intervals thereafter; pooled spleen cells from six or more donors were treated with xenoantibody or anti-Thy-1.2 and C'. Neonatal thymectomy delayed, but did not prevent the appearance of BAT⁺ cells (Fig. 3a). However, adult thymectomy produced a reciprocal decrease in the Thy-1⁺ cells and increase in BAT⁺ cells, so that at 5 weeks post-thymectomy these populations were numerically equivalent (Fig. 3b).

Dual specificity of Thy-1 alloantisera

The existence of a new murine antigen (BAT) unrelated to Thy-1, but restricted to brain and the T cell series seems unlikely. Alternatively, Thy-1 itself might define two serological determinants differing in temporal expression: 'conventional'

Fig. 2 Cytolytic effect of rat anti-AKR brain serum (▲, 1/6 dilution) or anti-Thy-1.2 (△, 1/16 dilution) and C' on CBA spleen cells of different ages.

Thy-1 present on neonatal and adult T cells, and a second specificity restricted to the adult. Alloantisera might then be expected to contain dual specificities, distinguished only by their reactivity with neonatal T cells.

To test this possibility, alloantisera (C3H anti-AKR, or AKR anti-C3H) were absorbed with 2–3-d-old spleens from either AKR or CBA mice and examined for residual activity. Absorption of Thy-1.2 (Fig. 4b) or Thy-1.1 (Fig. 4c) alloantisera had no effect on the cytotoxic titre for adult tissues but removed all activity for neonatal spleen. The age of the spleen cells used for absorption was critical; 8–10-d-old donor cells removed all cytolytic activity.

Plateau values for the percentage of cells lysed (thymus, spleen and lymph node) were obtained with alloantiserum dilutions of $\log_2 2-6$ (Fig. 4a; cytotoxic index and titre of anti-Thy-1.1 identical, data not presented). Absorption reduced these values for each tissue to give profiles strikingly similar to those obtained with xenoantisera (Fig. 1); thymus 80%, spleen 18–20%, lymph node 30–35%. Adult AKR thymus (Fig. 4c; 50%) was the obvious exception. These results suggested that xenoantisera and absorbed alloantisera were recognising the same cell population. To confirm this, cytotoxic values were obtained after consecutive addition of alloantisera and C', and xenoantiserum and C', to CBA or AKR spleen, or lymph node cells. The number of cells lysed remained unaltered after addition of xenoantiserum.

Murine alloantisera are frequently contaminated with viral antibody, leading to some confusion over serological specificity. It might be argued that the lymphocytotoxic antibody, removed by absorption with neonatal spleen, was directed against viral determinants, residual activity being *bona fide* Thy-1 antibody (Fig. 4b, c). This argument presupposes the absence of T cells in neonatal spleen; this is unlikely, as monoclonal Thy-1.2 antibody and C' lysed 30–35% CBA spleen cells from both 3-d-old and adult donors. Also, xenoantiserum and absorbed Thy-1.1 alloantibody lysed an equivalent number of spleen cells (20%) in

Fig. 3 Effect of neonatal (a) or adult (b) thymectomy on the number of CBA spleen cells lysed by rat anti-AKR brain serum (▲, 1/6 dilution) or alloanti-Thy-1.2 serum (△, 1/16 dilution) and C'.

congenetic A strain mice, where Thy-1.1 occurred on a different genetic background.

Lymphocytotoxicity compared with immunofluorescence

Lymphocytotoxic tests often give spurious results due to the presence of non-complement-fixing antibodies. Failure to lyse all T cells with xenoantibody or absorbed alloantibody might be an artefact of C fixation, and misinterpreted as a new serological specificity. It was necessary, therefore, to confirm these estimates by a different technique. Indirect immunofluorescence is a reliable method of detecting cell-bound antibody, although staining of lymphocytes with alloantibody or rat antibody includes a high background staining of immunoglobulin-bearing B cells. This background may be reduced by an initial 'capping' of B cells with antiglobulin.

Reasonable agreement was obtained by indirect immunofluorescence and no more than 20% of spleen cells bound xenoantibody or absorbed alloantibody. Both tests, therefore indicate that the sera are specific for a subpopulation of T cells.

Significance of a second Thy-1 alloantigen

We have shown that Thy-1 alloantisera contain two distinct antibody specificities, distinguished by absorption with neonatal T cells, whereas xenoantisera recognise a Thy-1 determinant restricted to the adult T cell.

The *Thy-1* locus, *Thy-1^a* and *Thy-1^b* alleles, is on chromosome 9 of the mouse, and there is no evidence of polymorphism¹². Biochemical studies in the rat, however, indicate molecular heterogeneity of Thy-1. Williams *et al.*, using lectin-affinity chromatography, have resolved Thy-1 from rat thymocytes into two components with molecular weights of 25,000 and 27,000 (ref. 13). Differences in lectin affinity were attributed to the carbohydrate moiety rather than the polypeptide. It is reasonable to assume that the dual specificities, defined here, also reflect post-translational modification of Thy-1, possibly by glycosylation. It may be anticipated that monoclonal Thy-1 antibodies, produced by hybridoma cell lines, will be specific for either 'conventional Thy-1' or the 'alternative Thy-1' defined here.

We describe below our attempts to attribute a function to the T cell population reacting with xenoantibody (anti-BAT), and the alloantibody, absorbed with neonatal spleen cells (anti-Thy-1 ab).

Phenotype of helper T cells

Helper T cell function was assayed by adoptive cell transfer. Spleen cells from normal or adult-thymectomised mice were transferred, together with sheep red blood cells (SRBC) as

immunogen, into lethally irradiated syngeneic mice; recipients were assayed for anti-SRBC plaque-forming cells (PFC) after 6 d.

The anti-SRBC response requires helper T cell cooperation. Pretreatment of donor lymphocytes with anti-Thy-1 and C abolished the development of direct and indirect PFC (Table 2, group 1). However, removal of >50% of T cells with anti-BAT or anti-Thy-1 ab and C had no effect on the primary anti-SRBC response, and even elevated the number of indirect PFC. Spleen cells transferred from mice, adult-thymectomised 4 months previously, developed a reduced number of PFC in irradiated hosts (Table 2, group 2). Here, in contrast, the number of PFC was reduced even further by anti-BAT or anti-Thy-1 ab and C. Cells from normal mice, primed 4 months earlier with SRBC, developed an increased number of PFC (Table 2, group 3). Treatment with anti-BAT and C now reduced the number of indirect PFC but had no effect on direct PFC. These results indicate that helper cells in the primary response to SRBC are BAT⁺ Thy-1 ab⁻, but BAT⁺ Thy-1 ab⁺ in thymectomised mice; in a secondary response, only a proportion of helper cells are BAT⁺.

The increased number of indirect PFC from the virgin donors treated with antibody and C may be due to elimination of suppressor T cells, but as we have no experimental system to generate or estimate such, this cannot be confirmed.

Phenotype of killer T cells and their precursors

Two experimental protocols were used either an adoptive cell transfer of CBA lymphocytes into lethally irradiated F₁ (CBA × DBA/2) recipients (*H-2^{k/d}*) to generate alloreactive (*H-2^d*) killer cells, or challenge of normal or adult-thymectomised, CBA mice with allogeneic tumour. Killer activity was assayed by the chromium release method using the P815Y tumour as a target.

Pretreatment of donor lymphocytes, or recipient F₁ cells at the time of assay, with anti-BAT or anti-Thy-1 ab and C had no effect on killer activity, indicating that neither precursor nor effector cells expressed the antigen(s) (Table 3, group 1). However, contradictory results were obtained in the second series of experiments (Table 3, group 2). Normal CBA mice were immunised with allogeneic tumour and killer activity was assayed at various times thereafter. Optimum killer activity was generated at 12 d; between 12 and 18 d ⁵¹Cr release was unaffected by antibody and C, whereas at 22 or 35 d values were reduced to base line.

This finding was constantly reproducible. Killer cells became susceptible to cytotoxic treatment with antibody and C at 20–23 d following immunisation. In CBA mice thymectomised as adults and challenged with allogeneic tumour 5 weeks later,

Fig. 4 Cytotoxic titre of Thy-1 alloantisera before (a, anti-Thy-1.2) and after (b, anti-Thy-1.2; c, anti-Thy-1.1) absorption with neonatal spleen. Alloantisera (Searle Diagnostic) were absorbed (1/4 dilution) with an equal volume of packed neonatal spleen cells, either CBA or AKR (1:1, v/v; 2 h at 3 °C) and assayed for residual cytotoxic activity: adult thymus (○), lymph node (□), spleen (△), neonatal spleen (Δ).

Table 2 Effect of xenoantibody or alloantibody and C' on the generation of a primary and secondary antibody response to SRBC in irradiated hosts

Group	Cell source	Direct PFC per 10 ⁶ cells	Indirect PFC per 10 ⁶ cells
1	Spleens of virgin CBA mice, treated with*:		
	NRS+C'(<2%)†‡	1,193 (898–1,439)	1,781 (1,635–2,126)
	Anti-BAT+C'(20%)†	1,524 (1,111–2,083)	3,016 (2,142–3,640)
	Anti-Thy-1.2+C'(32%)†	138 (90–221)	293 (192–442)
	Anti-Thy-1.2 ab+C'(18%)†	1,030 (972–1,094)	1,736 (1,370–2,187)
2	Spleens of adult-thymectomised CBA mice, treated with*:		
	NRS+C'(<2%)†	296 (257–358)	920 (708–1160)
	Anti-BAT+C'(24%)†	127 (107–145)	205 (187–237)
	Anti-Thy-1.2 ab+C'(21%)†	81 (64–116)	237 (209–262)
3	Spleens of primed CBA mice, treated with*:		
	NRS+C'(<1%)†	3,299 (2,931–3,742)	28,666 (25,000–33,250)
	Anti-BAT+C'(18%)†	3,517 (3,302–3,716)	14,020 (13,096–14,721)
	Anti-Thy-1.2+C'(34%)†	673 (531–789)	5,035 (3,986–5,580)

Spleen cells from six or more mice were pooled and assayed for PFC by the slide method, as described by Dresser¹⁹. Values for PFC per 10⁶ spleen cells represent the mean and range for six individual determinations.

* Viable lymphocytes were obtained by Ficoll-Hypaque centrifugation of CBA spleen cells. An equal volume of cells (4×10^8 ; 1 ml), C' and normal rat serum (NRS, 1/3 dilution), or anti-BAT (1/3 dilution), or anti-Thy-1.2 (1/8 dilution), or anti-Thy-1.2 ab (1/8 dilution) were incubated for 30 min at 37 °C. Lymphocytes (2×10^7 ; 0.3 ml) and SRBC (10^8) were injected intravenously into irradiated (900 R) CBA mice. Recipient mice were killed after 6 d.

† Number of cells lysed by antiserum and C' before adoptive transfer.

killer activity was always eliminated by anti-C' antibody (Table 3, group 3).

CBA mice are exceptional; their killer cells express a Ly-1⁺2⁺3⁺ phenotype whereas most other strains, including C57BL/6, are Ly-1⁺2⁺3⁺ (ref. 14). Therefore, the experiments were repeated with C57BL/6 mice (Table 3, group 4) with similar results: killer activity was eliminated by anti-BAT and C' at 22 d but not at 12 d. One may conclude that pre-killer and killer T cells are BAT⁺, Thy-1 ab⁺, whereas memory killer cells are BAT⁺ Thy-1 ab⁺.

A two-compartment model of antigen expression

Figure 5 schematically summarises our results. Two compartments for the peripheral T cell population are defined antigenically, BAT⁺ Thy-1 ab⁺ and BAT⁺ Thy-1 ab⁺. These antigens are distinct from any other lymphocyte differentiation antigen so far described in that they are markers of time not function. This may allow the estimation of transit time between

two cell compartments: virgin (or primary effector) cells and mature (or memory) cells. Lymphocytes leaving the thymus are BAT⁺ Thy-1 ab⁺. Removal of the source of precursor cells (by adult thymectomy) produces a majority of BAT⁺ Thy-1 ab⁺ peripheral T cells within 30–35 d (Fig. 3, Tables 2, 3).

The time required to generate memory killer T cells may also be estimated. After immunising normal CBA mice with allogeneic tumour, T killer cells are initially BAT⁺ Thy-1 ab⁺ (Table 3; 12–18 d) but within 20–23 d killer activity is present in the BAT⁺ Thy-1 ab⁺ population. In adult-thymectomised mice, killer cells are BAT⁺ Thy-1 ab⁺ at all times.

Raff and Cantor have proposed two major categories of peripheral T cells¹². The T₁–T₂ concept was a useful working model which gave some rationale to earlier reports of synergy between different Thy-1⁺ cell populations^{16,17}. T₁ cells were defined as short-lived, non-recirculating lymphocytes that were susceptible to adult thymectomy. T₂ cells were long-lived, recirculating lymphocytes; they were resistant to adult thymectomy but highly sensitive to the *in vivo* effect of anti-lymphocyte serum. This T₁–T₂ classification is somewhat overshadowed by

Table 3 Effect of xenoantibody or alloantibody and C' on the generation and activity of alloreactive, killer T cells

		22	68	10	10	ND

* Viable lymphocytes, obtained by Ficoll-Hypaque centrifugation, were treated with antiserum and C', as in Table 1. Donor lymphocytes (2×10^7 ; 0.3 ml) were injected intraperitoneally into irradiated (900 R) F₁ hosts.

† Irradiated F₁ recipients were killed at 7 d; spleen cells were treated with NRS, or antiserum, and C' and assayed for killer activity.

‡ Mice were injected intraperitoneally with 10⁷ P815Y tumour cells and killed at various time intervals (12–35 d). Ficoll-Hypaque-purified spleen cells were treated with NRS, or antiserum, and C' before assaying for killer activity.

§ Spleen cells (2×10^7 /ml) were incubated with ⁵¹Cr-labelled tumour (2×10^5 /ml) for 5 h at 37 °C, centrifuged, and radioactivity in the supernatant determined. Values are given for % of total radioactivity in the supernatant; complete target lysis is equivalent to 75–80% release. Spontaneous release of ⁵¹Cr, in the absence of spleen cells, was 8–12%. ND, not determined.

Fig. 5 A scheme of differential antigen expression by murine lymphoid cells.

recent studies with the Ly alloantigens^{7,8}, however, in functional terms, the T_2 population includes both $Ly-1^+$ helper and $Ly-2^+3^+$ suppressor/killer cells, and T_1 represents the precursor population of $Ly-1^+2^+3^+$ cells.

Some analogies may be made between $Ly-1^+2^+3^+$ (or T_1) lymphocytes and the $BAT^- Thy-1 ab^-$ population (Fig. 5). In the neonate, T cells are exclusively $Ly-1^+2^+3^+$ and $BAT^- Thy-1 ab^-$ (Figs 2, 4b, c) and both account for 50% of the adult population (Figs 1, 4b, c); the numbers of $Ly-1^+2^+3^+$ cells and $BAT^- Thy-1 ab^-$ cells (Fig. 3b, Tables 2, 3) are decreased after adult thymectomy⁷. The $Ly-1^+2^+3^+$ phenotype, however, defines a precursor population that differentiates further to either helper ($Ly-1^+2^+3^-$) or killer ($Ly-1^+2^+3^+$) cells^{7,8}. The $BAT^- Thy-1 ab^-$ population includes precursor cells and primary effector cells, and antigen expression reflects time not function.

The above model (Fig. 5) presents an obvious paradox. In the adult mouse, equal numbers of peripheral T cells are $BAT^- Thy-1 ab^-$ and $BAT^+ Thy-1 ab^+$; both populations can generate killer cells and helper cells (Tables 2, 3). However, the effector cells in a primary immune response are exclusively $BAT^- Thy-1 ab^-$. Following adult thymectomy, effector cells are $BAT^+ Thy-1 ab^+$ and helper function is somewhat reduced. These findings imply that, during a primary immune response, there is

a selective recruitment of 'young' T cells which have just left the thymus.

Certain reservations must be made concerning helper function. Further experiments are required with limiting numbers of T cells, for both the primary and secondary antibody response of irradiated hosts, to demonstrate conclusively that most helper cells are $BAT^- Thy-1 ab^-$.

If this scheme is essentially correct and there is recruitment of young T cells, several predictions can be made and tested experimentally. For example, the ageing mouse shows a progressive decline in thymic function and a reduced antibody response¹⁸. The age-dependent changes in humoral immunity may mirror, or even be a consequence of, altered ratios in the two T cell compartments, in which case, old mice might resemble adult-thymectomised mice.

We thank Mrs Dianne Millican and Mrs Mary Holman for technical assistance, Dr D. W. Dresser for advice with the plaque experiments and Drs P. Lake and E. Clarke for monoclonal Thy-1,2 antibody. R.A.C. acknowledges financial support from Consejo Nacional de Ciencia y Tecnologia, Mexico

A suppressor mutation in the nematode acting on specific alleles of many genes

Robert H. Waterston

Sydney Brenner

MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

A suppressor mutation has been isolated in Caenorhabditis elegans through reversion analysis of a muscle-defective mutant. The suppressor mutation acts on specific alleles of at least six genes and in one case we have been able to show that it partially restores functional gene product to a mutant otherwise lacking that product. These and other features of the suppressor suggest that it acts at some step in information transfer, perhaps through mechanisms similar to those described previously in microorganisms.

In intergenic suppression, the effects of a mutation in one gene are alleviated by mutations in other genes. Many different suppressor genes have been found in microorganisms, where restoration of the wild phenotype is achieved by a variety of mechanisms. Some suppressor genes compensate for the ori-

ginal mutation by affecting subunit interactions in macromolecular assemblies¹⁻⁴. Others act more indirectly by providing alternative biochemical pathways⁵⁻⁷ or by changing the physiological balance of the cell^{8,9}. A particularly important class is that of informational suppressors (for review see refs 10-13), which alter the fidelity of translation of mutant messages to allow the production of functional gene product, by changes in either transfer RNA¹⁴⁻¹⁹ or some other component of the translation machinery¹¹.

The identification and analysis of suppressor genes in microorganisms have provided an approach to problems that were not readily accessible with other methods of study. In multicellular organisms, the analysis of mutants and their suppressors might lead to the identification of the primary products of genes participating in developmental pathways and thereby provide some hint of the molecular interactions involved in this complex

Table 1 Summary of the results of four 3-factor crosses used to locate *sup-5** in LGIII

Cross	Parental genotype	Number of each recombinant genotype obtained	
1	<i>e1464</i> + + + <i>unc-69</i> <i>dpy-18</i>	<i>e1464</i> + <i>dpy-18</i> 10	+ + <i>dpy-18</i> 0
2	<i>e1464</i> + <i>dpy-18</i> + <i>unc-69</i> +	+ <i>unc-69</i> <i>dpy-18</i> 12	+ + <i>dpy-18</i> 8
3	<i>e1464</i> + + + <i>unc-32</i> <i>dpy-18</i>	<i>e1464</i> + <i>dpy-18</i> 21	+ + <i>dpy-18</i> 0
4	+ + <i>e1464</i> <i>lon-1</i> <i>dpy-19</i> +	<i>lon-1</i> + <i>e1464</i> 6	<i>lon-1</i> + + 0

To establish linkage, 20 suppressed animals were picked from among the progeny of hermaphrodites of the genotype *unc-15/+*; *m/+*; *sup-5*+, with the marker (*m*) being tested *trans* to the suppressor. The progeny of these suppressed animals were inspected to confirm that the parent was homozygous for the suppressor and for the presence of the marker. In all cases, except when markers from LGIII were used, the progeny of approximately 2/3rds of the parents included *m* animals. With markers from LGIII, many fewer parents contained the marker mutation. The mutant alleles used in the crosses were *unc-69*(*e587*), *dpy-18*(*e364*), *dpy-19*(*e1259*) and *lon-1*(*e185*)²⁶. For the 3-factor crosses, appropriate double mutants were constructed and mated with males carrying the third mutation to obtain the hermaphrodites listed under parental genotype. Among the progeny, animals with a recombinant phenotype were selected. In crosses 1, 2 and 3, dumpy animals were picked and progeny of these animals examined to determine the recombinant genotype, taking advantage of the observation that *dpy-18*(*e364*) *sup-5*(*e1464*)/*dpy-18*(*e364*) + animals are partially suppressed but still obviously dumpy and that *dpy-18*(*e364*) *sup-5*(*e1464*) homozygotes are nearly fully wild. From cross 4, long recombinants were selected, as *dpy-19* is epistatic to *lon-1*. Strains homozygous for the recombinant chromosome were obtained, and the presence of the suppressor was ascertained by testing with *unc-15*(*e1214*).

* Gene names in *C. elegans* consist of an italicised 3-letter abbreviation for a general phenotypic character, (for example, *unc* for uncoordinated, *dpy* for dumpy and *sup* for suppressor) separated by a dash from an italicised number to denote the specific gene, for example, *sup-5*. When appropriate an italicised roman numeral may follow, to indicate the linkage group of the gene, for example, *sup-5* III. Mutation names consist of 1 or 2 lower case italicised letters (used to indicate the laboratory of origin) followed by an italicised number, for example, *e1464*. *e* denotes mutations from the Cambridge collection and *st* denotes mutations from the St Louis collection. When gene and mutation names are used together the gene name is followed by the mutation name in parentheses, for example, *sup-5*(*e1464*) III. Strain names consist of 1 or 2 non-italicised upper case letters (indicating the laboratory of origin) followed by a number, for example, E1464. For most single mutants, strain and mutation names have the same letter and number but differ in typecase and by typeface, for example, the strain E1464 and the mutation *e1464*. Strains with multiple mutations are designated by the 1- or 2-letter laboratory prefix, a dash and a single upper case letter indicating the type of multiple mutant and number. Thus R is used to denote revertant strains, for example B-R215.

process. Especially useful would be a set of informational suppressors, which could then be used to study a wide variety of genes. Although suppressor mutations have been identified in *Drosophila melanogaster* (see ref. 20 for list), the mechanism involved is only partially understood²¹⁻²⁷.

For several years we have been studying mutants with abnormal muscle in the nematode *Caenorhabditis elegans* to identify genes involved in muscle assembly. Of the 13 genes now known to affect muscle structure (R.H.W., unpublished) the products of two are now known: *unc-15* I specifies paramyosin²⁹ and *unc-54* I specifies a major heavy chain of myosin³⁰⁻³³ (see footnote to Table 1 for nomenclature). At both loci we have isolated mutants that produce altered products, as well as null mutants in which none of the relevant polypeptide product can be detected²⁹⁻³². Mutants in these genes are particularly suitable for studies of suppression, for a few animals with even marginally enhanced motility can be easily detected against the background of the original paralysed mutant. Effects of suppression on muscle structure can be screened by polarised light microscopy, and biochemical analysis of the consequences of suppression can be readily carried out with the null mutants.

Reversion analysis of a large set of mutants with severely defective movement has already been carried out and some suppressor genes have been identified (refs 34, 35 and S.B., unpublished). In none of these cases is the molecular mechanism of compensation understood. In particular, Riddle and S.B.³⁴ have characterised a suppressor (*sup-3* V) that partially reverses the phenotypic effects of many alleles of *unc-15*, *unc-54* and *unc-87* I, another gene affecting muscle (R.H.W., unpublished). This and other evidence suggest that *sup-3* probably acts indirectly.

We report here the identification of a different suppressor (*sup-5* III) isolated initially in reversion studies of E1214, a mutant of *unc-15* that is very paralysed, is fertile, but does not lay eggs, and contains no detectable paramyosin²⁹. The suppressor is allele-specific but not gene-restricted, suppressing

only some alleles in several different genes. It also has the important property of partially restoring paramyosin in animals homozygous for *e1214*. These observations suggest that *sup-5*(*e1464*) III might be an informational suppressor.

Isolation and preliminary genetic characterisation of the suppressed strain R215

Approximately 10⁵ E1214 animals, treated with 0.05 M ethyl-methane sulphonate³⁵, were deposited on one side of 24 10-cm Petri plates. No full revertants appeared over the next three generations, but several plates contained animals with possibly improved movement. Most of these were later discarded but one strain that showed distinctively improved mobility was retained. Adults of this strain were larger than the E1214 strain and laid eggs, and the uniformity of the phenotype in the progeny indicated that the revertant was homozygous. F₂ progeny from a cross of the revertant with wild-type males showed that the revertant contained the original *e1214* mutation as well as an unlinked suppressor mutation (*C. elegans* normally reproduces as a self-fertilising hermaphrodite. It is diploid, with five autosomal linkage groups (I-V) and a sex linkage group (X). Males, which are hemizygous for the sex chromosome, are used to transfer genetic material. Heterozygous hermaphrodites can be allowed to self-fertilise to obtain homozygous animals.) From this cross a homozygous suppressed strain was re-isolated and propagated as the strain E-R213. To remove extraneous mutations, this strain was first crossed with *dpy-5* *unc-15*(*e1214*)/+ + males to obtain a dumpy suppressed strain which was in turn crossed with *unc-15*(*e1214*)/+ males to remove the dumpy marker. This yielded the strain E-R215 which was homozygous for both *e1214* and the suppressor allele, designated *e1464*. E-R215 grows better than E-R213, but motility and other characteristics do not differ appreciably.

Mapping the suppressor, *e1464*, in linkage group III

Location of the suppressor on linkage group III (LGIII) was determined initially from 2-factor crosses in a homozygous *e1214* background using general genetic methods described previously³⁶. An estimate of 7 map units between *dpy-18 III* and the suppressor was obtained, and results with *dpy-19 III*, *sma-2 III* and *lon-1 III* indicated that *e1464* was located less than 4 map units from these markers. As no previously mapped suppressors were in this region, *e1464* was assigned to a new gene *sup-5 III*. A strain containing the suppressor in a wild-type background, E1464, was obtained by elimination of the *lon-1* marker from a *lon-1 +/+ e1464* animal.

A male stock of the E1464 strain was generated from spontaneously occurring males to facilitate the transfer of the mutation in further genetic manipulations. Several 3-factor crosses were carried out to position the suppressor more precisely (Table 1). In progeny of hermaphrodites of the genotype *sup-5(e1464) +/+ unc-69 dpy-18* in cross 1, all the dumpy recombinants contained the suppressor, indicating that *sup-5(e1464)* lies to the left of *unc-69* or very close to it. From cross 2, only 12 of 20 dumpy recombinants contained the *trans* mutation *unc-69*, clearly placing *sup-5* to the left of *unc-69*. A third cross was carried out with *e1464 trans* to *dpy-18* and *unc-32*, a gene 3% to the left of *unc-69*. All dumpy recombinants contained the suppressor. A left-hand limit was established in cross 4, where *sup-5* was shown to lie to the right of *lon-1*. Crosses 3 and 4 place *sup-5* very close to *dpy-19* and *unc-32*, two genes that are themselves only 0.1% apart (Riddle, personal communication).

Phenotype of E1464

The E1464 strain moves normally, and its muscle structure as observed with polarised light microscopy²⁹ is indistinguishable from wild type. However, the strain shows some differences from wild type. Sterile animals are produced frequently, particularly when the strain is grown at 15 °C instead of room temperature (22 °C). Occasionally, dead early larvae and other abnormal forms have been noted. The generation time is increased to 7.5 d at 15 °C from the normal wild-type time of 5.5 d. Male stocks have been very difficult to maintain. Doubles of *e1464* with the linked markers *e364* and *e185* exhibit similar characteristics. This fact, together with the several crosses undergone in the construction of the E1464 strain makes it probable that these properties are due to the suppressor mutation itself.

Range of suppression by *e1464*

The *e1464* suppressor has been combined with a large number of different mutants of many genes to test for suppression. While mapping *e1464*, the phenotype of many mutants was found to be unaffected by *e1464*. These include the dumpy mutants *dpy-5(e61) I*, *dpy-10(e128) II*, *dpy-18(e189) III*, *dpy-13(e184) IV* and *dpy-11(e224) V*; the uncoordinated mutant *unc-32(e189) III*; the long mutant *lon-1(e185) III*; and the small mutant

sma-2(e502) III (ref. 36). However, *dpy-18(e364) III* gave anomalous results in initial mapping experiments, and subsequently it was shown that *e364* is suppressed by *e1464*. In strains homozygous for both *e364* and *e1464*, animals are nearly wild type in length and diameter when grown at 15 °C (Table 2).

Additional double mutants have been constructed to test the specificity of *e1464*-mediated suppression. In the *unc-15* complementation group, the mutant allele, *e73*, which results in a dysfunctional paramyosin, is not suppressed even though the null allele, *e1214*, is.

unc-54 mutants have also been studied, as the gene product is known to be a myosin heavy chain³⁰⁻³³. More than 30 independent mutations are available, and these have been classified into two groups; mutants of the larger class contain no detectable *unc-54* myosin, whereas those of the other contain approximately normal levels of gene product³¹. This second class is assumed to have altered product and, in fact, one mutant, E675,

Fig. 1 Comparison of total SDS-soluble proteins from the nematode strains N2, E-R215 and E1214. Animals were grown in liquid culture, collected⁴⁰ and frozen²⁹ until use. Care was taken to obtain cultures of animals in similar larval stages to minimise possible developmental variations. 15 μ l of a 1:7 (v/v) dilution of each sample was applied to an SDS-polyacrylamide gel³⁹. The gel was stained with Coomassie brilliant blue, destained and photographed.

Fig. 2 Electron micrographs of body wall muscle from the three strains, N2, E-R215 and E1214. Adult animals grown at 20 °C were prepared for microscopy as previously described²⁹, and transverse sections were viewed and photographed with an AEI EM5B electron microscope. Magnification 30,000 $\times$.

Table 2 Mutation suppression by *e1464*

Gene	Phenotype	Alleles suppressed by <i>e1464</i>	Alleles not suppressed by <i>e1464</i>
<i>unc-15 I</i>	Muscle defective (paramyosin)	<i>e1214</i>	<i>e73</i>
<i>unc-54 I</i>	Muscle defective (myosin heavy chain)	<i>e576, e1108</i> <i>e1021, e1008,</i> <i>e1419</i>	<i>e190, e569, e651,</i> <i>e675, e903,</i> <i>e1009, e1092,</i> <i>e1115, e1168, e1201,</i> <i>e1258, e1274, e1300,</i> <i>e1315, e1328, e1420,</i> <i>st1, st2, st3</i> <i>e309, e323, e328,</i> <i>e973, e1038, e985,</i> <i>e387, e51, e158</i> <i>e499</i>
<i>unc-13 I</i>	Severely uncoordinated	<i>e312, e376,</i> <i>e450, e1091</i>	<i>e903</i>
<i>dpy-18 III</i>	Dumpy	<i>e364</i>	NA
<i>cat-1 X</i>	Catecholamines lacking neuronal processes	<i>e1111</i>	NA
<i>nuc-1 X</i>	Lacks deoxyriboendonuclease	<i>e1392</i>	NA

Doubles of the suppressor with each of the above autosomal mutations were constructed by the elimination of markers closely linked either to the suppressor or to the mutant to be tested. For example, E1464 males were mated with the double mutant *unc-54; sma-2*, and six paralysed or slow F_2 progeny (those homozygous for *unc-54*) were selected. The progeny of each animal was inspected for suppressed animals. Those animals that did not segregate small progeny were assumed to be homozygous for *e1464*, as *sma-2* is less than 2% from *sup-5*. For sex-linked mutants, suppression was evaluated directly by observing the phenotype of males produced from a cross of mutant hermaphrodites with *e1464/+* males. In the case of *nuc-1*(*e1392*), 63 of 148 male progeny were suppressed and with *cat-1*(*e1111*), 60 of 129 males had suppressed phenotypes, in good agreement with the predicted ratio. All the mutations listed, as well as those described in the text, were isolated after EMS treatment³⁶ except *e903* (X-ray mutagenesis)³⁰, *e1258* (DES mutagenesis) and *e1168* and *e1201* (ICR-22 mutagenesis) (Riddle, personal communication). Some of the mutants of *unc-15* (ref. 29), *unc-54* (refs 30, 31), *unc-13* (ref. 36), *nuc-1* (ref. 38), *dpy-18* (ref. 36), and *cat-1* (ref. 37) loci have been described previously. Only those which showed clear phenotypic suppression were scored as positive. NA, no other independent mutants are available for this locus.

has been shown to contain a small internal deletion in its heavy chain³². Of the 22 null mutants tested, five show clear phenotypic suppression. The suppressed animals move even as adults, lay eggs and attain a full adult size. Nonetheless, suppressed animals move much more slowly than wild type and are clearly distinguishable from them. Neither *e675* nor *e1274*, mutations resulting in altered proteins^{30,31}, is suppressed.

Several independent mutants that are extremely uncoordinated have been isolated in *unc-13 I*. Reversion studies had been previously carried out with mutants in *unc-13* and several alleles had been found to be suppressible by unlinked suppressors (S.B., unpublished). Of 13 alleles tested, four are suppressed by *e1464*. When both the suppressible *unc-13* allele and *e1464* are homozygous, animals have nearly wild-type movement; suppression is also apparent in animals homozygous for the *unc-13* allele but heterozygous for the suppressor. The suppressor mutation is semidominant. To test the effect of temperature on the suppressed strains, all the double strains have been grown at 15 °C and 25 °C. In all cases, the suppression is more pronounced in animals grown at 15 °C, consistent with the idea that the difference in suppression at the two temperatures is associated with the suppressor *per se*. These observations correlate with the increased sterility and slow growth noted at 15 °C in the E1464 strain.

Lastly, mutant alleles of two genes that have no relationship to muscle function or structure have also been tested. One, *cat-1*(*e1111*) X, alters the distribution of formaldehyde-induced fluorescence in catecholamine-containing neurones³⁷, and the other, *nuc-1*(*e1392*) X, results in the loss of detectable deoxyriboendonuclease activity³⁸. Phenotypically, the latter mutation results in the persistence of pyknotic nuclei of cells undergoing programmed cell death and in the presence of undigested DNA in the lumen of the digestive tract; these alterations are easily detected in Feulgen-stained animals. Clear suppression of both mutations was found when the suppressor was present only in a single dose (Table 2).

Mechanism of suppression

Because the protein products of *unc-15* and *unc-54* genes are known, suppressible mutations in these genes facilitate the determination of the molecular consequences of suppression. The E1214 strain contains essentially no paramyosin and virtually no normal thick filaments in the body wall muscle cells²⁹

(Figs 1, 2). When the total SDS-soluble proteins from the suppressed strain R215 are analysed by polyacrylamide gel electrophoresis, a faint band with a mobility similar to the paramyosin band from N2 is present, whereas among the E1214 proteins no such band is seen (Fig. 1). In addition, a protein has been purified from E-R215 showing mobility identical to wild-type paramyosin on SDS gels, but the yield of paramyosin is only about 10% of that obtained from wild type. Paracrystals have been prepared from R215 paramyosin and, when viewed with the electron microscope on negatively stained grids, they seem to be similar to paracrystals of wild-type paramyosin. Cyanilation cleavage of the E-R215 protein with 2-nitro-5-cyanobenzoic acid⁴¹ results in five fragments which have the same mobility on SDS gels as those obtained from wild-type paramyosin.

The structure of E1214 body wall muscles is also affected by the suppressor. By polarised light microscopy, E-R215 shows an increased birefringence, mostly localised in poorly defined, nearly longitudinal bands (presumably A-bands). In electron micrographs of transverse sections, E-R215 displays several of the ultrastructural features of E1214, but in addition, clusters of filaments having the diameter and appearance of wild-type thick filaments are present among abundant thin filaments. These thick filaments are much less numerous and less well ordered than in N2 (Fig. 2).

Preliminary analysis of the suppressed myosin mutant strain *unc-54*(*e576*); *sup-5*(*e1464*) indicates partial restoration of wild-type muscle structure. Myosin has been purified from the strain, but because myosin heavy chains in *C. elegans* are the products of more than one gene^{30,31}, it is more difficult to determine if the *unc-54* myosin is restored by the suppressor. However, cyanilation cleavage yields peptides that are unique products of the *unc-54* heavy chain³¹, and initial experiments indicate partial restoration of these peptides in *unc-54*(*e576*); *sup-5*(*e1464*). The large number of mutants in this gene may allow us to determine whether the restoration of gene product by the suppressor always correlates with phenotypic suppression.

Conclusion

Our experiments show that *e1464* suppresses mutants of several different genes, including two that code for muscle proteins, as well as others that are clearly not related to muscle. In the genes

in which several independent mutations are available, only a few of the mutants are suppressible; most are unaffected by *e1464*. The extent of phenotypic suppression is different in mutants of different genes: *unc-15* and *unc-54* mutants are weakly suppressed, whereas with *dpy-18*, *unc-13*, *nuc-1* and *cat-1* mutants a nearly wild-type phenotype is restored. These phenotypic differences probably reflect the functions of the gene products, as the weakly suppressed mutants involve proteins that are required stoichiometrically to form the muscle lattice. One of the well-suppressed mutants, *nuc-1*, affects an enzymatic function, and perhaps the others do also.

In E-R215, the suppressor partially restores the specific gene product (paramyosin) affected by *e1214*. This is also apparently the case with the suppressible myosin mutants. It is likely that in the double mutant *sup-5(e1464); nuc-1(e1392)*, endonuclease activity has been restored, but no direct tests have been carried out.

The suppressor is semidominant, or dose dependent. The heterozygous suppressor *e1464/+* is clearly effective in the strongly suppressed mutants, and a slight effect of the heterozygous suppressor can also be detected in *unc-15* and *unc-54* mutants. It should be feasible to demonstrate some restoration of paramyosin in *e1214/e1214; e1464/+* animals. The suppressor alone exerts a deleterious effect on the animal, particularly at low temperatures, where suppression of mutant phenotypes is greatest.

None of the *unc-15* and *unc-54* mutants which contain altered gene products is suppressed and the suppressor seems to act only on a subset of null mutants. We do not yet know why the null mutants are devoid of gene product. If ethylmethane sulphate produces principally G to A transitions in the nematode as it does in microorganisms⁴², then nonsense mutations producing premature chain termination are likely to account for most of the large set of null mutants. As yet, no truncated fragments have been identified in these mutants, but it is possible that they are degraded after formation or lost in purification. The mutant E675 does contain a shortened chain, but this results from a small internal deletion which leaves the C-terminus intact³². Thus the *e1464* mutation may be a specific nonsense suppressor analogous to those found in microorganisms, perhaps acting through an altered tRNA species. On the other hand, the suppressible mutations may affect some other step of information transfer and the suppressor may alter another component of the machinery. Further genetic and biochemical studies should reveal which of these possibilities is correct.

The mutant alleles used in the crosses were from the Cambridge collection. Additional alleles were from the St. Louis

collection. This work was initiated during the tenure of an MDA fellowship to R.H.W. at the MRC Laboratory of Molecular Biology and continued at Washington University with grants from NIGMS and the Muscular Dystrophy Association Inc. to R.H.W. We thank Nicol Thomson and Santiago Plurad for the electron micrographs, T. R. Lane and H. R. Horwitz for useful comments, J. E. Sulston for carrying out the suppression tests with the *cat-1* and *nuc-1* mutants, and A. R. MacLeod for determination of *unc-54* myosin in the suppressed strain.

letters to nature

Contribution of intermediate luminosity X-ray galaxies to the background: Anon 0945-30

EVIDENCE that the galaxy A0945-30 is a new extragalactic X-ray source has been found from an analysis of rotating modulation collimator (RMC)¹ quick-look data collected from 53 orbits of the SAS 3 X-ray observatory during the period 26 February-2 March 1978. The exposure is approximately $7 \times 10^6 \text{ cm}^2 \text{ s}$. The galaxy lies within the error boxes quoted for 4U0945-30 and 2A0946-310 but is not one of the previously

suggested candidates. A faint star alongside the galaxy also lies in the 90% confidence X-ray source error circle (Fig. 1). The data are consistent with a point source². The flux from the source varied by a factor of about five during the period of our observation.

The SAS 3 RMC data alone do not allow a unique spectral fit. Fortunately, data from HEAO 1, (R. F. Mushotzky, personal communication) give a photon number index $\gamma = 1.8 \pm 0.1$ and a hydrogen column density of $N_H = 3 \pm 1 \times 10^{22} \text{ cm}^{-2}$ for a power law spectrum extending to about 35 keV. Using a 2 keV low-energy cutoff the SAS 3 data yield a slope identical with the HEAO 1 value. The X-ray flux density is $(4.5 \pm 0.6) \times 10^{-29} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ Hz}^{-1}$ at 10^{18} Hz (4.14 keV) and the 2-10 keV

Fig. 1 The SAS 3 90% confidence error circle (radius = 35") superimposed on a photograph of A0945-30. The measured position of the X-ray source is $\alpha(1950) = 9\text{ h } 45\text{ min } 28.4\text{ s}$, $\delta(1950) = -30^\circ 42' 36''$ and the position of the galaxy is $\alpha(1950) = 9\text{ h } 45\text{ min } 28.43 \pm 0.13\text{ s}$, $\delta(1950) = -30^\circ 42' 57.0 \pm 1.7''$.

X-ray flux is $(7.7 \pm 0.3) \times 10^{-11} \text{ erg cm}^{-2} \text{ s}^{-1}$. The measured heliocentric radial velocity is $2,498 \pm 15 \text{ km s}^{-1}$ and, with $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$, the average X-ray luminosity is $\sim 2.2 \times 10^{43} \text{ erg s}^{-1}$.

The hydrogen column density inferred from the X-ray spectral cutoff indicates that the galaxy A0945-30 rather than the star is the X-ray source. In the source direction, the hydrogen column density in the Galaxy is at most $\sim 2 \times 10^{21} \text{ cm}^{-2}$ (refs 3, 4), nearly an order of magnitude less than the column density obtained by Mushotzky (personal communication).

Recent observations by Liller (personal communication) indicate that the galaxy is an early type spiral (possible an Sa) with a bright nucleus. Detailed optical observations of the galaxy and the star were made with the new digital spectrograph on the 1.5-m telescope at Mt Hopkins observatory. The star is an F dwarf with no indication of emission features. Plates in the Harvard collection covering this field show no evidence for long term variability of the star (L. Chaisson and J. P. Huchra, personal communication). Spectra of the galaxy in the red (4,500–7,000 Å) and blue (3,900–6,000 Å) show sharp, intermediate strength emission lines of [OIII], [NII] and H α together with strong Mg, Fe, Ca absorption features characteristic of a normal stellar continuum in the galactic nucleus (Fig. 2). The absorption-corrected absolute magnitude of the galaxy is ~ -20.0 . No significant H β emission is present. The other emission lines present are just resolved at the instrument resolution of $\sim 200 \text{ km s}^{-1}$ FWHM or 300 km s^{-1} FW0I (full width zero intensity) (Fig. 2). This width is considerably smaller than the widths of 1,800 and 1,100 km s^{-1} FW0I reported by Ward *et al.*⁵ for H β in the X-ray emitting galaxies NGC2992 (2A0943-140) and NGC7582 (2A2315-428). The width is also smaller than the $\sim 1,800 \text{ km s}^{-1}$ FW0I for H β (refs 6, 7) in NGC 5506 (refs 8, 9). NGC 2992, NGC 7582 and NGC 5506 are similar to weaker type 2 Seyferts. The emission line equivalent widths are much smaller in A0945-30 than in NGC 5506 (20 Å as opposed to 200 Å for $\lambda 5007$ Å) which could be due to larger extinction of the nuclear source; the correction for dilution by the galactic continuum in our long slit (4" $\times$ 25") observation only increases the emission line equivalent widths for A0945-30 by a factor of ~ 2 . The excitation of both galaxies is quite high with $I(\lambda 5007)/I(\text{H}\beta) \sim 10$ in NGC5506 and ≥ 20 in A0945-30.

Our optical observations of the galaxy A0945-30 strengthen the case for its identification with the X-ray source. Previously, it would have been unreasonable to identify A0945-30 with 4U0945-30 or 2A0946-310 because of the large area error boxes associated with these non-modulation collimator observations. Identifications would be made only when well-known objects which are members of established classes of X-ray emitters were in the error box.

A0945-30, NGC5506, NGC2992 and NGC7582 are members of an X-ray optical luminosity class characterised by X-ray luminosities of $\sim 10^{43} \text{ erg s}^{-1}$ and with $-20.5 \leq M_B \leq -19.0$. The number density of all galaxies in this absolute magnitude range is $\sim 10^{-2} \text{ Mpc}^{-3}$ (ref. 10). The $10^{43} \text{ erg s}^{-1}$ X-ray galaxies could, therefore, be numerous and it is interesting to speculate on the possibly significant contribution of

Fig. 2 *a*, A spectrum of A0945-30 obtained during a 15-min integration with the new digital spectrograph on the 1.5 m Mt Hopkins telescope. *b* and *c*, enlarged sections of the spectrum showing prominent emission and absorption features. The data have been smoothed to the resolution limit of about 5 Å. The detector has a resolution of ~ 1.8 Å per pixel.

objects in this range of the X-ray-optical luminosity function to the X-ray background.

In the 1–20 keV range the X-ray background intensity $I(E) = 8.5E^{-0.5 \pm 0.2} \text{ keV (keV}^{-1} \text{ cm}^{-2} \text{ s}^{-1} \text{ ster}^{-1})$ (ref. 11). If the emissivity of extragalactic X-ray sources per unit co-moving coordinate volume is independent of cosmological epoch, then already-known classes of discrete sources (Seyferts, quasars, clusters of galaxies) can account for at most 40% of the X-ray background¹². The X-ray luminosity density required to account for the remaining 60% of the background intensity is $\sim 10^{39} \text{ erg s}^{-1} \text{ Mpc}^{-3}$. The required number density of $10^{43} \text{ erg s}^{-1}$ sources is 10^{-4} Mpc^{-3} . To account for the background, only 1% of galaxies in the magnitude range $-20.5 \leq M_B \leq -19.0$ need be $10^{43} \text{ erg s}^{-1}$ X-ray emitters.

The background spectrum ($\alpha = 0.5 \pm 0.2$) in the 1–20 keV range could be produced by discrete sources with a range of power law spectra. One consistent model for the distribution of spectral indices is a gaussian with mean spectral index $\bar{\alpha} = 0.5$ and dispersion $\Delta\alpha = 0.4$ (ref. 13). The spectra of A0945–30 ($\alpha = 0.8 \pm 0.1$) NGC5506 ($\alpha = 0.3 \pm 0.3$) and NGC7582 ($\alpha = 0.3 \pm 0.4$) (R. Mushotzky, personal communication) are all in the expected range.

Uhuru observations reveal fractional fluctuations in the 2–10 keV background intensity of $\delta I/I = 3.6 \pm 0.5\%$ for an effective solid angle of $\Omega \approx 0.004$ ster (ref. 11). If the 10^{43} erg s⁻¹ sources are randomly distributed with mean density 10^{-4} Mpc⁻³, the expected $\delta I/I \sim 2\%$, consistent with the observational limit. If these X-ray emitting galaxies are clustered in the same way as the general galaxy population¹⁴, the fluctuations are increased by at most a factor of 2.

The X-ray luminosities of individual clusters of galaxies ($\sim 10^{44}$ erg s⁻¹) (ref. 12) provide another constraint on the acceptable fraction of galaxies like A0945–30. Photometry of four X-ray clusters^{15,16} indicates that the expected mean number of 10^{43} erg s⁻¹ X-ray galaxies is at most one per cluster.

The SAS 3 RMC survey covers $\sim 5\%$ of the sky to a limiting flux of $\sim 2.5 \times 10^{-11}$ erg s⁻¹ cm⁻². A 10^{43} erg s⁻¹ source could be detected at a distance of ~ 60 Mpc. If the mean density of sources is 10^{-4} Mpc⁻³ the survey should have detected 4–6 sources in the $1\text{--}2 \times 10^{43}$ erg s⁻¹ range. The detection of three sources (A0945–30, NGC5506, and NGC7582) indicates that these galaxies may be sufficiently numerous to account for $\sim 50\%$ of the X-ray background. The number of sources required is also consistent with the number of unidentified sources in the high latitude ($|b^{\text{U}}| > 20^\circ$) Uhuru (ref. 17 and C. Jones, personal communication) and Ariel¹⁸ surveys which have limiting 2–10 keV sensitivities of 5×10^{-11} erg cm⁻² s⁻¹ and 6.1×10^{-11} erg cm⁻² s⁻¹ respectively. We expect Uhuru detection of 20–30 of these $1\text{--}2 \times 10^{43}$ erg s⁻¹ sources and Ariel detection of 15–20 such sources. To produce $\sim 50\%$ of the X-ray background intensity we require less than half of the completely unidentified high latitude sources in either survey to lie in this intermediate X-ray–optical luminosity range.

We thank A. Epstein, B. Flannery, R. Giacconi, D. Latham, F. Pineda, F. Rosenberg and J. Tonry for discussions and assistance with the observations, also R. Mushotzky for use of his data before publication. This work was supported in part by NSF contract AST76–22675, NASA contract NAS5–11450 and MIT subcontract SC22152.

SS Cygni as a hard X-ray source identified with the scanning modulation collimator on HEAO 1

X-RAY emission from the dwarf nova SS Cygni was first detected at soft ($\sim \frac{1}{2}$ keV) X-ray wavelengths when the source was in an optical high state^{1–3}. More recently, ANS satellite observers⁴ have reported the detection of soft X-ray emission when SS Cygni was in an optical low state. These latter observations show the flux of the soft X-ray source to be about an order of magnitude less than the values when in the optical high state. The soft X-ray positional uncertainty is ~ 0.2 deg². The correlation between optical and soft X-ray behaviour convincingly identifies SS Cygni as a soft X-ray source. Hard (> 1 keV) X-ray emission from a $15' \times 1.5''$ area containing SS Cygni was also reported by the ANS observers during the optical low state and identified with SS Cygni⁴. A more accurate position (0.03 deg²) has been reported by Ariel 5 observers⁵. We report here a 0.4 arc min² measurement of the position of the X-ray source with the HEAO 1 modulation collimator experiment which leads to an unequivocal identification of SS Cygni as an X-ray emitter in the 2–10 keV energy range. We have also searched the Uhuru data to investigate the historical light curve in hard X rays.

The +Y axis instruments of the HEAO 1 satellite were pointed at SS Cygni for two orbits on 16 December 1977, when it was in an optical low state. The modulation collimator (MC) experiment data were binned⁶ about the position of SS Cygni. We used only one orbit of data (~ 1 h of observing time) because of problems in the determination of the aspect for the second orbit. Moreover, we rejected an additional 18% of the data when there were rapid changes in the background level.

The ANS and Ariel 5 error boxes were used to reduce the multiplicity in our positional determination. Five MC diamonds (Fig. 1) are within the ANS error box and only one, which includes SS Cygni (Fig. 2), is in the Ariel 5 error box. The area within this diamond is 0.4 arc min². This is a more than 200-fold improvement with respect to previous results^{4–5}, and definitively confirms that SS Cygni is a hard X-ray emitter.

The MC flux (2–6 keV) is $(1.7 \pm 0.5) \times 10^{-10}$ erg cm⁻² s⁻¹ with an additional 30% systematic uncertainty. The fit of the three A-3 spectral channels to a bremsstrahlung spectrum with Gaunt factor and low energy cut-off gives an equivalent temperature $kT > 10$ keV and a low energy cut-off $< 0.2 \times 10^{22}$ N_H cm⁻².

Oscillations of small amplitude (< 0.002 mag) with a period of 9.75 ± 0.03 s have been reported in the optical flux of SS Cygni during an optical maximum (Robinson, personal communication). We searched our data for periodicities, by folding according to different trial periods and calculating the χ^2 value for the hypothesis of a constant flux. We did not find any significant enhancement in χ^2 that could be attributed to the presence of pulsations for periods in the range 5–20 s. The 3σ upper limit for the pulsed fraction is $\sim 13\%$ for periods consistent with that of the optical pulsations.

We have investigated the historical light curve in hard X rays by analysing all the relevant Uhuru data. SS Cygni was in the Uhuru field of view ($0.5^\circ \times 5^\circ$ FWHM) and not confused with nearby sources in 12 d of observations. These data are scattered over 1.5 yr, but they are always coincident with an optical low state. In two instances there was marginal evidence for source detection in the 2–6 keV band: at an intensity of $(4.4 \pm 2.7) \times 10^{-11}$ erg cm⁻² s⁻¹ on 20 June 1971 and at $(9.0 \pm 3.2) \times 10^{-11}$ erg cm⁻² s⁻¹ the following day. These are of the same order as the ANS and HEAO 1 fluxes. Ariel 5 observed SS Cygni for a period of 120 d (ref. 5) including both low and high optical states. While the equivalent 2–6 keV flux during low states is highly variable between 7 and 30×10^{-11} erg cm⁻² s⁻¹, in the optical high state there is only an upper limit (2σ) of 6×10^{-11} erg cm⁻² s⁻¹.

Fig. 1 One of the multiple MC positions (diamonds) falls within the previous location uncertainty measured by ANS (ref. 4) and Ariel 5 (ref. 5). This region has an area of 0.4 arc min^2 , and contains SS Cygni near its centre

The X-ray luminosity of SS Cygni in the 2–10 keV energy range is then of the order of $10^{33} \text{ erg s}^{-1}$ (for a distance of $\sim 200 \text{ pc}$) in the optical low state and probably at least an order of magnitude less in the high state. In contrast, the soft X-ray luminosity increases by an order of magnitude between the optical low and high states: from 2 to $30 \times 10^{31} \text{ erg s}^{-1}$ respectively. The average spectral behaviour (0.25–10 keV) of SS Cygni thus shows two distinct states correlated with the optical behaviour: the effective spectrum seems to soften during the optical high states.

SS Cygni is the brightest of the dwarf novae, with a visual magnitude ranging between 12.1 at minimum and 8.1 at maximum (see reviews by Glasby⁸ and Robinson⁹). Its light curve shows outbursts that repeat with an average period of 50.6 d, but with a range of periods between 33 and 71 d. It is a spectroscopic binary system composed of a normal late type star orbiting about a white dwarf with a period of 6 h 38 min. The masses of both

Fig. 2 Enlargement of the POSS region containing SS Cygni, showing the MC location precision.

components are estimated to be in the range $0.8\text{--}1.0 M_{\odot}$. The continuum emission seems to be yellow at the minimum of the light curve and blue-violet at the maximum. The spectrum is characterised by hydrogen emission lines at the beginning of the rise to the optical maximum and hydrogen absorption lines that become broader while the luminosity reaches the maximum.

It is believed (see Paczynski in Preprint No. 73 of the Polish Academy of Sciences) that the white dwarf and its accretion disk are the source of the optical and ultraviolet as well as the soft X-ray emission in the dwarf novae. There is observational evidence that links the emission and absorption lines to the accretion disk⁹. The soft X-ray flux could either originate from the boundary layer of the disk and the white dwarf¹⁰ or from the surface of the disk which could behave as a corona¹¹ (B. Paczynski, personal communication). The limited information on the hard X-ray emission does not permit us to discriminate between these two hypotheses. A coronal model can explain the inverse correlation of the soft and hard X rays which is also true if accretion on to the white dwarf is the production mechanism of the hard X rays. In the coronal hypothesis the soft and hard X-ray fluxes both originate in the accretion disk, due to the interaction of magnetic fields and plasma, analogous to the solar corona. As discussed by Galeev *et al.*¹¹ The hard X-ray flux can be produced in magnetically confined plasma (loops arising from the disk surface) while the soft X-ray flux arises from regions of less intense magnetic activity. The increase in the soft X-ray flux, which could result from an increase in the accretion rate during the optical maximum, would cause a decrease in the hard X-ray flux by comptonisation. If accretion on to the white dwarf is the production mechanism of the hard X rays, as in the model of Fabian *et al.*¹², the anticorrelation of the soft and hard fluxes could be explained by a variation in the optical thickness of the region emitting hard X rays. This might result from the increased density of the accreting gas during the optical outbursts. The soft X-ray flux, which originates further away from the surface of the white dwarf, is not likely to be affected in the same sense. Instead, the increase in the temperature of the accretion disk during optical maximum could enhance the soft flux. The accretion mechanism for SS Cygni is discussed in detail by Ricketts *et al.*⁵. The lack of a cut-off at the low energies in the hard X-ray spectrum of SS Cygni is consistent with the $\sim 35^\circ$ inclination of the orbit of the system and with accretion from a disk.

We thank B. Paczynski and J. Grindlay, and J. Mattei of the A.A.V.S.O. for useful discussions, and M. Conroy and T. Wilson for help in the data analysis. We thank the other members of the modulation collimator experiment team at the Harvard-Smithsonian Center for Astrophysics and the MIT Center for Space Research for their contributions, and J. Swank and D. Hearn for discussion of data before publication. The ANS error box for SS Cygni was provided by J. Grindlay. This research was sponsored by NASA contracts NAS8-30453 and NAS8-27972.

Long-term variability of galactic X-ray sources

THE long-term (days to months) variability of 32 persistent galactic X-ray sources brighter than Cas A in the energy range 3–10 keV is discussed here, using data from the MIT experiment on the OSO 7 satellite¹. For each X-ray source, we compiled a list of counting rates for all observations made during the first 600 d of operation of the experiment² (typically six or seven observations for each source). The results in these lists show the well-known high variability of the massive early-type X-ray binaries. Of special interest, however, are the variability characteristics of the sources associated with old populations. These include several near the galactic centre which are generally referred to as 'bulge' sources, and several which are known to lie in globular clusters. They share certain similar X-ray characteristics, namely, spectra which are markedly softer than those of massive binaries and an apparent absence of pulsations and eclipses^{3–6}. Because of their similarities, it has been suggested that they are all systems of the same kind, such as neutron stars in low mass binary systems^{7,8}, or the products of core collapse in globular clusters⁹. However, our results show that the long-term variability of the bulge sources is generally much less than that of the sources which lie in globular clusters. This suggests that there is a substantial difference between the bulge and globular cluster sources either in their nature or, at least, in certain critical properties of their components such as the masses of the nuclear-burning companions which may supply the material for accretion by compact objects in binary systems.

Only those sources at galactic latitudes in the range $|b^{\text{II}}| < 10^\circ$ were included in our study. An average counting rate was derived for each observation of each source. A typical observation lasted several days and was separated from other observations of the same source by periods ranging from a few days to a few months. The duration of each observation was sufficiently long to average out the effects of eclipses of the X-ray binaries. We considered only data from our 3–10-keV detectors because they were largely uncontaminated by solar X rays or trapped particles. For this study we selected a subset of sources that were sufficiently bright so that variations of intensity >10% would be discernible. Specifically, we chose those sources for which, during at least one observation, a counting rate greater than two standard deviations above 2.5 counts s^{-1} was measured. This intensity is roughly that of the Perseus Cluster and the Cas A X-ray sources, generally believed to be nonvariable and which could, therefore, be used as standards (see ref. 2 for details).

For each source we computed a parameter which measures the variability from observation to observation. This parameter is defined by

$$\xi = \alpha / \bar{x} \quad \text{where} \quad \bar{x} = \frac{\sum_i (x_i / \sigma_i^2)}{\sum_i (1 / \sigma_i^2)}$$

$$\text{and} \quad \alpha = \left(\frac{\sum_i (x_i - \bar{x})^2 / \sigma_i^2}{\sum_i (1 / \sigma_i^2)} \right)^{1/2}$$

where x_i is the counting rate for each observation and σ_i is the

statistical uncertainty associated with each counting rate. The summations are carried out over all the observations of the sources in question. $\bar{x}$ is the mean counting rate and α is the r.m.s. deviation of the counting rates from this mean. (Each intensity measurement is weighted by its errors, see ref. 10.) ξ , defined as $\alpha / \bar{x}$, represents a measure of the fractional fluctuation of the x_i about $\bar{x}$. (We have not considered, in detail, the intensity distribution functions of all the sources.)

We also computed a parameter defined by

$$\Delta\xi = \bar{\sigma} / \bar{x} \quad \text{where} \quad \bar{\sigma} = \frac{\sum_i 1 / \sigma_i}{\sum_i 1 / \sigma_i^2}$$

$\bar{\sigma}$ is taken to be the magnitude of typical errors in the intensity measurements. The parameters of all the sources were computed for the two sets of data collected by the detectors behind the 1° and 3° collimators separately¹.

Fig. 1 The variability measure ξ is plotted against the spectral hardness (KR/AR) for the sources listed in Table 1. Standards (S) are the Crab Nebula, the Perseus Cluster and Cas A; GB (x), galactic bulge sources; GC (■), sources in globular clusters; B, binary X-ray sources; and T, transient X-ray sources. Those sources in Table 1 that are not yet known to be one of the above classes are plotted as dots.

Table 1 summarises the results on all the sources that satisfy the above selection criteria. The value of ξ listed for a source is the higher one from the two data sets. If the values of ξ measured for a source are comparable in the two sets, the one with a smaller $\Delta\xi$ is listed. Also listed are the value of $\Delta\xi$ and the number of observations (ν) for that source. We emphasise that $\Delta\xi$ should not be viewed as an error for ξ but merely as an indication of the counting statistics in the various measurements. For an X-ray source with constant intensity, the expected value of ξ is $\sim \Delta\xi$. The sources in Table 1 are ranked in increasing ξ ; also included are the Crab Nebula, the Perseus Cluster and Cas A which are generally believed not to vary significantly on

the time scale under study. The observed values of ξ and $\Delta\xi$ for these sources indicate that they are nonvariable (within an uncertainty $\Delta\xi$). As systematic errors affect the results for weak sources more than those for strong ones, we limited our study to sources brighter than Cas A.

Figure 1 shows the relationship between long-term variability and spectral hardness as characterised by the ratio of the counting rate in the 15–40-keV channel to that in the 3–10-keV channel². As expected, Table 1 and Fig. 1 show the high variability of young massive binary sources (BI). In contrast, the bulge sources (GB) are, for the most part, either steady or only slightly variable. The six least variable sources (excluding the 'standard' sources) are GB sources. The absence of long-term variability is, therefore, a distinguishing characteristic of the bulge sources.

The sources in globular clusters (GC), on the other hand, vary in about the same degree as the young binary sources. Although the sample of GC sources is small, two of the three in our list are much more variable than any of the GB sources. Three other globular cluster sources, NGC1851, NGC6712 and M15, which failed to make our list because of their low intensities, are also known to be highly variable¹¹.

Sources of type I X-ray bursts are found both inside and outside globular clusters (for example, the burst source associated with the globular cluster NGC6624 (refs 12, 13) and MXB1735-44 which is identified with an isolated faint blue star¹⁴⁻¹⁶; for detailed properties of X-ray burst sources, see ref. 17). It seems likely that the globular cluster sources and all the type I burst sources, both inside and outside globular clusters, form a class of similar objects (F.L. and G.C. in preparation).

They could, for example, be non-magnetised neutron stars in low-mass binary systems (see ref. 18 for a model). If the bulge sources near the galactic centre are, as we conjecture, of the same nature, then the systematic difference in the long-term variability must be attributed to differences in some critical parameter(s) affecting the mass transfer process. One such parameter, for example, may be the mass of the nuclear burning companion. The typical mass of the nuclear burning companion of an X-ray binary in the core of a globular cluster would be $\sim 0.5 M_\odot$. Low-mass X-ray binaries formed outside globular clusters such as by the evolution of cataclysmic variables¹⁹ may have nuclear burning companions with masses of $\sim 1.0 M_\odot$.

We thank Professors C. Canizares, J. Ostriker and S. Rappaport for helpful discussions.

Definition of a black hole

TIPLER has given a new definition for a black hole¹. These objects had previously been properly defined only in asymptotically flat spacetimes², but it seems unlikely that our Universe is one of these. One of the well known properties of a black hole, proved in asymptotically flat spacetimes, is that its 'surface area' can never decrease. By means of this new definition Tipler has shown that this area theorem may well not be true in our Universe. However, Tipler's definition is complicated, and it is not obvious that it corresponds to our usual concept of a black hole. I show here that it is equivalent to a definition that is both simpler and more clearly a formalisation of what we mean by a black hole.

I use the notation of refs 1 and 2. Let T be the set of points of a stably causal spacetime which belong to non-cosmological trapped surfaces. Tipler defines a black hole as the closure of the topologically-smallest future set I^+ such that I^+ contains T , and the boundary of I^+ is generated by (future inextendible) null geodesic segments which are boundary generators of TIPs.

We would like a black hole to contain T . It should not be possible to escape from a black hole, so the hole should also contain $I^+(T)$. Furthermore, any points from which it is impossible to avoid falling into a black hole might as well be said to be within that hole. That is, a black hole should be the closure of $B = D^-(I^+(T))$. I shall show that B satisfies the conditions set out by Tipler for I^+ .

B is a future set: suppose $x \in B$ and $y \in I^+(x)$. There is a future directed timelike curve from x to y . If it meets $I^+(T)$ then $y \in I^+(T)$, so $y \in B$. If it does not meet $I^+(T)$, it must do so when extended along any future directed non-spacelike curve α from y as $x \in D^-(I^+(T))$. Therefore, any such α meets $I^+(T)$, so $y \in B$.

The boundary of B is generated by null geodesic segments which are boundary generators of TIPs: let x be on the boundary of B . Let (x_i) be a sequence of points lying to the past of x , not in B , with x as their limit point. There is a future inextendible non-spacelike curve γ , from each x_i that does not enter $I^+(T)$. By proposition 6.2.1. of ref. 2 there is a future inextendible non-spacelike curve γ from x which is a limit curve for the γ_i .

As $\bar{B}$ is a closed future set γ can never leave it. As no γ_i can enter B , γ cannot enter the interior of B . But $I^+(\gamma) \subset B$, so γ cannot enter its own future. Therefore, it must be a null geodesic.

$\bar{I}(\gamma)$ is a TIP (see ref. 3). As γ cannot enter its own future it cannot enter its own past, $I^-(\gamma)$. Therefore, it is a boundary generator of $I^-(\gamma)$.

It remains to be proved that B is the smallest such I^+ . It has been shown that from any point on the boundary of B there is a future directed null geodesic γ that does not enter the interior of B , so cannot enter $I^+(T)$. Therefore, the boundary of B is not part of B , and B is open.

Suppose there is an I^+ that is contained in B but not equal to it. We can then find a point p which is in B but not in I^+ . Let α be a future directed timelike line from p . It must meet $I^+(T)$, and hence must enter I^+ . Let it cross the boundary of I^+ at y . There is a future directed null geodesic generator γ of the boundary of I^+ from y . It is future inextendible, and cannot enter $I^+(T)$ as otherwise it would be in the interior of I^+ . Thus, by proceeding from p along α to y then along γ , we can construct a future inextendible non-spacelike curve from p which does not meet $I^+(T)$. This contradicts $p \in B$.

Therefore B is the smallest such I^+ , and the black hole defined by Tipler is exactly $\bar{D}^-(I^+(T))$.

Neutrinos from binary pulsars

PULSARS are believed to produce high energy particles. If high energy protons produced by the pulsar strike a target, say a binary companion, high energy neutrinos are produced in the collisions. At the same time, schemes for detecting high energy neutrinos produced in nature are currently being considered (refs 1-4 and K. Lande, personal communication). Here we point out that binary systems containing moderately young pulsars (ages $T < 10^4$ yr, that is comparable to NP0532) may emit high energy neutrinos ($10^{12} < E_\nu < 10^{14}$ eV) at detectable levels. Such pulsars are assumed to have total luminosities of the order 10^{38} erg s⁻¹. Discussion of feasible neutrino telescopes (such as the deep underwater muon and neutrino detector, DUMAND¹⁻⁴) suggests that fluxes from point sources as small as 10^2 - 10^3 eV cm⁻² s⁻¹ in high energy neutrinos may eventually be detectable. Neutrino detectors on a more modest scale, such as that of Lande (personal communication) will be operating within 1-3 yr, and have detection thresholds of 10^5 eV cm⁻² s⁻¹. Thus, a pulsar emitting 3×10^{34} erg s⁻¹ in high energy neutrinos at 3 kpc would be detectable even with Lande's detector, and the DUMAND detector may be able to detect sources that are weaker by three to five orders of magnitude.

We assume that at least some of the pulsars emit a fair fraction ($\approx 1\%$) of their energy in the form of high energy protons ($10^{13} < E_p < 10^{16}$ eV). This energy range is consistent with the upper limit⁵ of the potential near the star

$$V_{\text{max}} = 10^{16} (B/10^{12} \text{ G})(\Omega/200 \text{ s}^{-1})^2 V \quad (1)$$

where B is the magnitude of the magnetic field at the stellar surface, and Ω is the frequency of rotation. That young pulsars can produce very energetic particles is implied by the very energetic ($E_\gamma \approx 10^{12}$ eV) pulsed γ rays⁶ emitted by NP0532. The energy in the protons is converted efficiently to high energy neutrinos if either the protons traverse more than ~ 50 g of material, or they traverse a column density of 10^{28} photons cm⁻² in photons that are not too far above the pion production threshold in the rest frame of the protons. In each case, the protons are stopped by pion and kaon producing processes, and the charged mesons that are produced decay into three neutrinos and an electron. Roughly half the energy in the original proton goes into high energy neutrinos, which typically have energies of the order $10^{-2} E_p$ to $10^{-1} E_p$ (ref. 3).

There are several plausible ways in which the high energy protons might encounter enough target material to convert 1% to 50% of their energy to neutrinos.

If the companion star fills its Roche lobe, it could occupy nearly half the sky as seen from the pulsar, thus blocking a proportionate fraction of the high energy protons. Moreover, the overflowing material may completely engulf the pulsar.

Accreting matter can pile up at the magnetopause (which in the case of a pulsar would be made up of very low frequency electromagnetic Alfvén waves). It has been suggested^{7,8} that such a pile up occurs in several intermediate and rapidly rotating binary X-ray sources.

Or, the accreting matter might settle into a disk much smaller than the binary orbit, and much larger than the light cylinder. Such a disk could have a random orientation relative to the rotation axis of the pulsar, and could block a fair fraction of the protons leaving along open field lines. Moreover, as the disk may be substantially heated by such protons, it is likely to have a corona that completely engulfs the pulsar.

Besides being a target itself, matter near the pulsar can scatter and trap photons that also may serve as a target. To fix the ideas, suppose that 10^{38} erg s^{-1} of X rays are emitted by the pulsar and diffuse away from it through surrounding matter. Assume the scale height of the photons is 3×10^8 cm and that their mean free path is λ ($\lambda < 3 \times 10^8$ cm). Then the density of photons at the scale of 3×10^8 cm is $3 \times 10^{19}(\lambda/3 \times 10^8 \text{ cm})^{-1}$, enough to stop all the protons by photopion production.

Finally, we discuss stellar winds. Suppose the pulsar's companion is an OB supergiant. Motivated by standard models of binary X-ray sources⁹, we assume a mass loss rate $\dot{M} = 10^{-5} M_{\odot} \text{ yr}^{-1}$, a wind velocity near the pulsar of $V = 300 \text{ km s}^{-1}$, and a binary orbit radius of 3×10^{11} cm. Then the column density of the wind surrounding the pulsar is of the order of (depending on direction) $1\text{--}10 \text{ g cm}^{-2}$, thereby providing a significant target. Reasonable parameters for red giants, $\dot{M} = 3 \times 10^{-6} M_{\odot} \text{ yr}^{-1}$, $v = 10 \text{ km s}^{-1}$, $R = 3 \times 10^{13}$ cm, yield a comparable column density. Pulsar emission impinging on the companion could stimulate a wind regardless of its type as has been suggested¹⁰ for the case of Cyg X3.

Assuming a pulsar formation rate of one every 10 yr (ref. 11), there ought to be $\sim 10^3$ moderately young pulsars in the Galaxy at present and more if pencil beaming effects allow a selection efficiency of only a few per cent. Older pulsars, though less powerful, are more numerous, and may also be detectable in neutrinos. Direct evidence that neutron stars can form without disrupting the binary system (such as binary X-ray sources) combined with the observation that a significant fraction of all stars (at least $\sim 50\%$ (ref. 13) perhaps most¹⁴) are in binaries allows the hypothesis that a significant fraction of these young pulsars are in binaries.

One route for binary pulsar formation particularly favourable to neutrino production is that a helium star or white dwarf, accreting the Roche lobe overflow from a red giant companion, becomes massive enough to explode, leaving a pulsar. (An explosion is not necessary, the pulsar may form quietly¹².) Just after the explosion, the companion to the young pulsar is automatically in the stage where its extended envelope and overflow play a significant role as target material.

It is difficult to predict the *a priori* probability of detecting, by conventional means, any pulsars that might exist in binary systems. First, there are beaming effects. Moreover, if there is some mechanism that accelerates pulsars to $\sim 250 \text{ km s}^{-1}$ at their inception (refs 15, 16 and refs therein), only the ones that are tightly bound—to relatively massive companions—are likely to remain in their binary orbit. Hence accretion clouds become an important factor. Most binary pulsars are unlikely to appear in radio surveys as their accretion clouds and the coronas of their companions would generally have plasma frequencies in excess of the radio. (The only binary pulsar found by Hulse and Taylor had a compact companion; one might expect many more with main sequence companions.) If they are blanketed by more than 1 g cm^{-2} , their pulsation could not be detected at any frequency, and if by more than $\sim 30 \text{ g cm}^{-2}$, no non-thermal photons are likely to escape because they would first be degraded to energies below 10 keV, where they would then be absorbed by partially ionised iron and oxygen^{13,17}.

Cyg X3, generally presumed to be a pulsar in a binary system, is blanketed by $\sim 10 \text{ g cm}^{-2}$ (ref. 10), and is deduced to be a pulsar only by virtue of its γ -ray emission. Cyg X3 itself may be detectable in high energy neutrinos if it emits $\geq 10^{35}$ erg s^{-1} in high energy protons. There may also be a whole class of objects like Cyg X3, but obscured by much thicker envelopes.

Hefand and Tademaru¹⁶ noted a distinct class of pulsars with very low transverse velocity. To account for this, they suggest

that $\sim 20\%$ of all pulsars form in close binary systems, probably in a 'cataclysmic binary' sequence such as outlined here. (The pulsar is later released gently from the binary as the companion sheds mass.) High energy neutrino astronomy would provide an opportunity to test such a hypothesis. Conversely, their hypothesis suggests that there may be many interesting astrophysical phenomena to observe with neutrino telescopes. We emphasise that if high energy particles generated by the pulsar manifest themselves by bombarding the corona or envelope of the companion star, the mesons and photons they produce are directed into the star. Hence high energy neutrino astronomy may be the only way to detect high energy phenomena in such systems.

Constraints on the corona model for Sirius B

SINCE the discovery of Sirius as a soft X-ray source¹, two models have been proposed to account for the emission—thermal emission from deep layers of an almost pure hydrogen atmosphere², and an acoustically heated corona around the white dwarf (WD) Sirius B (ref. 3). Both models seem unsatisfactory in some respects: the thermal emission model does not agree with the recently revised upper limits found from extreme UV observations⁴, and the T_{eff} of Sirius B is much too large for H-convection. In this note we re-examine the constraints on the corona model in the light of historical records suggesting a possible pseudo-red giant phase a few thousand years ago.

Sirius B does have an H-atmosphere, and with T_{eff} being $32,000 \pm 1,000 \text{ K}$ (ref. 5), the atmosphere is stable against convection. If it is accepted that the corona is due to the dissipation of the acoustic flux produced in subatmospheric convective layers, then for Sirius B to have a corona there must be an He-convective region beneath the atmospheric H-layers. Fontaine⁶ argues that in this case the acoustic flux produced would be much too low to satisfy the energy requirement to heat the corona. However, the theory of corona formation is not well developed⁷, and the computation of acoustic fluxes is critically dependent on the theory of superadiabatic convection. Hence, if convection survives in the subatmosphere of Sirius B, we cannot exclude the corona model. In fact, Lampton and Mewe⁸ recently revised the energetic requirements for white dwarf coronae and

claim that the corona around Sirius B may exist, provided that the H-layer is very thin.

The theory of white dwarf envelopes is already sufficiently good to quantify what 'very thin' means. The H mass M_H must be larger than the mass which provides Rosseland optical depth $\tau = 1$, as we see an H-atmosphere, but smaller than the mass which does not allow He-convection to survive. We constructed atmosphere and subatmosphere models for Sirius B according to the data given in refs 9 and 10. The models consist of an H-envelope down to a fixed mass point, of a μ zone, in which the chemical composition smoothly changes from H to He (ref. 11), and of an He mantle. At the T_{en} (from 30 to 33×10^3 K) and gravity (corresponding to $M = 1 M_\odot$) of Sirius B we find $2 \times 10^{16} \leq M_H < 10^{17}$ g.

It is difficult to believe that Sirius B is born exactly with this H-envelope. We might expect that it was born with a pure He atmosphere, like DB white dwarfs, and that it accreted H from the stellar wind of Sirius A during the white dwarf lifetime ($t = 3-4 \times 10^7$ yr, ref. 12). Since it is now clear^{13,14} that He white dwarfs do not accrete from interstellar matter at the rates predicted by Bondi's accretion formula¹⁵, but the geometrical accretion rate is appropriate¹⁰, one may derive the mass loss rate ($\dot{M}$) from Sirius A which accounts for the required M_H , simply as:

$$M_H = \dot{M} \pi R_s^2 / (4 \pi d^2)$$

where R_s is the Sirius B radius (5.5×10^8 cm) and d the system separation (20 AU). This relation provides $3 \times 10^{-13} \leq \dot{M} < 2 \times 10^{-12} M_\odot \text{ yr}^{-1}$, which is not an unreasonable rate for a $2 M_\odot$ star. Therefore, the corona model for Sirius B cannot be excluded on the basis of these arguments. If the white dwarf, corona-like emission were confirmed, we should know, with an uncertainty of a factor of only 10, the rate of mass loss from Sirius A.

However, we feel that the historical record of Sirius being a red star should not be dismissed as unpalatable. Most of the references to this (Greek, Roman, Egyptian) were collected at the end of last century by Schiaparelli^{16,17}, who did not believe that Sirius could have changed colour, because, in his time, the theory of stellar evolution predicted that stars evolved from white to red, and then to total darkness—'as a piece of iron cooling from white heat'. Further historical quotations—not so complete—are given by See¹⁸, who, unlike Schiaparelli, believed that the historical evidence strongly suggested that a colour change had taken place. If the historical records are to be believed, Sirius must have changed colour from red to white between the epoch of Ptolemy (AD 100) and the epoch of Al-Sûfi (AD 980), within 800 yr.

We now know with reasonable certainty that the age of Sirius as a white dwarf cannot be so low, but we also know that hot white dwarfs are not always 'normal' stars: instabilities connected to H burning in thin shells can be found, and these may last few thousand years¹⁹. Therefore, we cannot rule out the possibility that Sirius B went through a pseudo-red giant phase a few thousand years ago.

In this context, we emphasise that the sudden expansion of the outer envelope of a white dwarf is always related to H burning, which may occur only if the H envelope of the white dwarf is large ($\geq 10^{28}$ g), and the expansion for a few thousand years is never able to completely remove this envelope. In other words, if the historical record is true, then the H envelope of Sirius B is orders of magnitude larger than the envelope required for He convection to survive, and the corona model is wrong.

Hence, if it is found that Sirius B does indeed produce a corona-like emission, and if further study of historical records and archaeological evidence indicates a pseudo-red giant phase, the theory of generation of a corona by acoustic flux dissipation must be seriously questioned. The acoustic flux model will also be in doubt, if the coronal X-emission is shown to arise from Sirius A, since Sirius A, like Sirius B, cannot have subatmospheric convection.

We thank P. Maffei for bringing our attention to Schiaparelli's work, M. A. Giannuzzi for her interest in the history of Sirius, and R. Mewe for useful discussions.

If the Sun has a companion . . .

HARRISON¹ has suggested on the basis of pulsar data that the Sun might have a companion. This letter discusses some of the implications if such a companion is a compact object, more precisely a neutron star (NS) or a black hole (BH). Using existing accretion results, it is argued that it is impossible to rule out either a NS or a BH as a possible candidate. However, constraints can be placed on the allowed mass range and/or radiation mechanisms. If such a compact object exists, the probability of observing the gravitational lens effect can be substantial.

The case for a low-mass star, a black or a white dwarf has been discussed by Henricks and Staller² who concluded that such an object would be conspicuous in the visible or IR sky and would probably have already been detected. The situation for a NS or a BH is not quite so clear and one needs to consider in more detail the luminosity achieved through accretion.

Because a weakly bound binary system may not survive the explosion leading to a NS or a BH, we only consider the simple case of a close encounter between our Sun and its postulated temporary companion. The probability of such an encounter or its perturbing effects on planetary motions will not be discussed here. The accretion rate $\dot{M}$ is of the order³ $\dot{M} \approx 4 \pi G^2 M^2 \rho_0 / (a_0^2 + v^2)^{3/2}$ where ρ_0 and a_0 are the density of the unperturbed ambient gas and the corresponding speed of sound, and M and v are the mass and velocity of the compact object. As $a_0 \approx 10 \text{ km s}^{-1} (T/10^4 \text{ K})^{1/2}$ and as we expect $v \gg 10 \text{ km s}^{-1}$, the accretion rate⁴ will be of the order $\dot{M} \approx 3 \times 10^{-16} (M/M_\odot)^2 (n_0/1 \text{ cm}^{-3}) (v/10 \text{ km s}^{-1})^{-3} M_\odot \text{ yr}^{-1}$, where n_0 is the particle number density of the unperturbed gas. Taking first the case of a BH and using previous results obtained for spherical accretion from a medium at $T \approx 10^4 \text{ K}$ (as a_0 is then of the order 10 km s^{-1} , this is equivalent to considering a BH moving through the interstellar medium at $v \approx 10 \text{ km s}^{-1}$), we write the total luminosity in the form⁴⁻⁶

$$L_{\text{BH}} = \Lambda_{\text{BH}} (M/M_\odot)^3 (n_0/1 \text{ cm}^{-3})^2 (v/10 \text{ km s}^{-1})^{-3}$$

where the quantity Λ_{BH} and the spectral energy distribution depend on the details of the model. (For the models considered here, $\Lambda_{\text{BH}} \approx 10^{21} - 10^{29} \text{ erg s}^{-1}$.) As for accretion on to a NS, most (if not all) of the energy is radiated away so that $L_{\text{NS}} =$

$\eta GMR^{-1} \dot{M}$, where R is the radius of the NS. Taking $\eta \approx 0.3$ and $M/R \sim 10^5 M_\odot/R_\odot$ for a $1 M_\odot$ NS, and assuming a crude mass-radius relationship of the form $MR^3 \approx \text{constant}$, the total luminosity takes the form $L_{\text{tot}} = \Lambda_{\text{NS}} (M/M_\odot)^{10/3} (\rho_0/1 \text{ cm}^{-3})^{1/3} (v/10 \text{ km s}^{-1})^{-3}$, where $\Lambda_{\text{NS}} \approx 10^{30} \text{ erg s}^{-1}$. Again, the spectrum depends on the detailed processes by which the radiation is emitted.

Taking the distance d to the companion (as determined by the required acceleration of order $10^{-6} \text{ cm s}^{-2}$ for the Solar System) to be $d = 800(M/M_\odot)^{1/2} \text{ AU}$, we can now obtain the apparent visual magnitude V and expected X-ray intensity I in c.p.s. (counts per second) in the range 2–6 keV (1 count $\approx 1.7 \times 10^{-11} \text{ erg cm}^{-2}$), provided the spectral distribution of the radiation is known. For different parameters the quantities V and I vary according to

$$I = \text{const} \times M^{a-1} n_0^b v^{-3}$$

$$V = \text{const} + 2.5((1-a) \log M - b \log n_0 + 3 \log v) \quad (1)$$

with $(a, b) = (3, 2)$ for a BH and $(10/3, 1)$ for a NS. With respect to the X-ray intensity I , we note that on the basis of X-ray data⁸ there are 14 sources in the expected¹ direction of the companion, that is $17 \text{ h } 30 \text{ min} < \text{RA} < 19 \text{ h } 52 \text{ min}$, $-27^\circ < \delta < 32^\circ$. Six of these are close to the general direction to the galactic centre and thus probably associated with it, so we need not consider them. Of the eight sources left, all have an intensity $< 270 \text{ c.p.s.}$

Figure 1 shows V plotted against $\log I$ giving the results corresponding to various radiation processes around accreting NS or BH for the case $n_0 = 1 \text{ cm}^{-3}$, $v = 10 \text{ km s}^{-1}$ and $M_{\text{NS}} = 1 M_\odot$, $M_{\text{BH}} = 10 M_\odot$. The fact that each case is represented by an area instead of a point reflects the uncertainties in estimating the amount of energy emitted in the visible and X-ray bands. (The IR magnitude K also generally correlates with the V magnitude so that a bright visible object would also be a bright IR object.) The three NS results are labelled 1, 2 and 3 on Fig. 1.

Fig. 1 V magnitude and (2–6 keV) X-ray intensity I corresponding to various radiation processes, discussed in the text, around accreting NS (dotted areas 1, 2 and 3) and BH (hatched areas 4, 5, 6 and 7). The parameters used are: $n_0 = 1 \text{ cm}^{-3}$, $M_{\text{NS}} = 1 M_\odot$, $M_{\text{BH}} = 10 M_\odot$ and $v = 10 \text{ km s}^{-1}$. The three arrows on the left of the diagram illustrate the shift in the position of three arbitrary points (●) if M and v are changed as shown. Arrows leading to points marked X and Y refer to specific changes discussed in the text. An object could have possibly remained undetected until now only if its corresponding point on the diagram lies inside the region indicated by the heavy line, that is $V > 9$, $I < 270 \text{ c.p.s.}$

As the emitted spectrum is complex and depends strongly on the actual physical processes (for a review of accretion on to a NS, see ref. 7), we have not tried to represent realistic situations. Instead, we have assumed some simple radiation mechanisms to illustrate the wide range of possible results. Hence, cases 1 and 2 correspond respectively to black-body emission at $T \approx 10^5$ – 10^6 K and bremsstrahlung at $T \approx 10^6 \text{ K}$ (in the latter case, comptonisation if taken into account would augment the high-energy end of the spectrum). In case 3, a shock above the surface is assumed to heat the electrons to a high temperature of the order of 10^{12} K , and V and I are estimated by assuming that the bulk of the energy is in the form of γ rays and that the spectral distribution does not increase at lower energies. The four BH results, labelled 4, 5, 6 and 7, were obtained from earlier work on accretion. For the chosen models, the emission is predominantly due, in case 4 to radiative recombination and bremsstrahlung⁴, in cases 5 and 6 to electron synchrotron radiation^{5,6,14}, and in case 7 to bremsstrahlung, thermal and cosmic ray electron synchrotron radiation¹⁵.

Clearly, for either a NS or a BH, the results are very sensitive to the details of the emission process. In particular, a NS companion can certainly not be ruled out, especially because increasing the velocity to 100 km s^{-1} , and taking a lower mass (all observed NS masses⁹ seem to lie in the range $0.3 \leq M/M_\odot \leq 1.2$) substantially favour the possible existence of a NS companion (all points get shifted diagonally downwards parallel to the arrows on the diagram). As for a BH candidate, if Shvartzman's model or Mészáros' is the correct one (areas 6 or 7 on Fig. 1, large synchrotron luminosity including contribution from cosmic ray electrons in Mészáros' case), then a BH companion, in order not to be one of the brightest objects in the visible sky, would have to have either $v \gg 10 \text{ km s}^{-1}$ or $M \ll 10 M_\odot$ or both (for example, a $1 M_\odot$ BH moving with velocity $v = 100 \text{ km s}^{-1}$ would have $V \approx 9$). Note that a BH of $1 M_\odot$ would have to be primordial in origin. It is interesting that, taking the maximum allowed cosmological density¹⁰ of BH and a velocity of the order 100 km s^{-1} , an encounter at the required distance every 10^8 – 10^9 yr is expected independent of the mass of the BH (both the number of BH, and the square of the distance depend linearly on the mass of the BH). On the other hand, taking Shapiro's model or equivalently assuming the magnetic field to be relatively unimportant (areas 4 and 5 on Fig. 1), then one sees that a BH with $M \leq 10 M_\odot$ and $v \geq 10 \text{ km s}^{-1}$ could easily have remained undetected until now. Wright¹¹ has suggested a supermassive black hole of $M > 6 \times 10^3 M_\odot$ moving with $v > 9 \text{ km s}^{-1}$ as a possible solar companion. Compared to a $10 M_\odot$ BH, such a BH would have a luminosity larger by a factor of order 4×10^5 (corresponding to $\sim 14 \text{ mag}$). Regardless of the accretion model adopted, this BH would be very conspicuous in both or either of the visible and X-ray sky and is thus highly unlikely as a candidate.

Could one of the already observed X-ray sources be this postulated companion? Of the eight aforementioned X-ray sources listed in the 3U catalogue⁸, one, 3U1832–23, lies on the ecliptic (thus minimally disturbing the orbit of the planets). For this source $I = 6.9 \pm 0.9 \text{ c.p.s.}$ If this source were the solar companion, then we could certainly rule out cases 1, 5, 6 and 7. On the other hand, assuming the kind of simple spectra used in Fig. 1, a NS having $M \approx 1 M_\odot$, $v \approx 10 \text{ km s}^{-1}$ could possibly be a candidate but only if electrons were heated to a very high temperature (case 3, but then it should also be a strong γ -ray emitter). Another possibility would be a NS with a basically thermal bremsstrahlung spectrum at $T \approx 10^6 \text{ K}$ (case 2) provided $(M/M_\odot)^{7/3} (v/10 \text{ km s}^{-1})^{-3} \approx 2 \times 10^{-5}$ (this change of parameters would shift the position of a point in dotted area 2 diagonally to a point X at $V \approx 21$), a typical example being $M \approx 0.3 M_\odot$, $v \approx 140 \text{ km s}^{-1}$. An accreting BH with a simple bremsstrahlung spectrum (case 4) could also be a candidate if $(M/M_\odot)^2 (v/10 \text{ km s}^{-1})^{-3} \approx 200$. This resulting increase in luminosity (shift to a point Y on Fig. 1) could be achieved, for example, with a $150 M_\odot$ BH moving at $v = 10 \text{ km s}^{-1}$. Such a BH would be at $d \approx 9,000 \text{ AU}$ and would have a proper motion

$\mu_0 \approx 45 \alpha \text{ arc s yr}^{-1}$ and parallax $\pi \approx 20 \text{ arc s}$, with α the ratio of tangential to total velocity.

It has been assumed so far that a value of $n_0 = 1 \text{ cm}^{-3}$ is typical of the interstellar medium. The actual density outside the Solar System¹⁶ may well, however, be only of the order 0.1 cm^{-3} . If this is the case, the luminosities derived from accretion are then reduced by a factor of 100 for a BH and 10 for a NS, thus making any such compact object even less conspicuous.

Another aspect of interest is the question of whether gravitational lensing by the postulated companion can have observable consequences. Wright¹¹ has briefly commented on this point. We calculate here the probability that the compact object will act as a moving lens causing an angular displacement and brightening up of distant background stars. To appreciate the angles involved, a typical angle is the angular radius of the annular image of a distant source when there is perfect alignment. This angle γ_0 (half the angle α_0 used by Refsdal¹²) is given by

$$\gamma_0 = 1.47 \text{ arc s } (M/M_\odot)^{1/4}$$

where the distance-mass relation is used for the postulated companion and the fact that this distance is considerably smaller than the star-deflector distance. For a seeing disk of 1 arc s, the above relationship shows that the deflector and primary image (the only one we consider here) are separately resolved. The amplification factor, defined as the ratio of the lensed flux to the unlensed flux is given by¹² $A = \frac{1}{4}(2 + (\alpha/\beta) + (\beta/\alpha))$, where $\alpha^2 = \alpha_0^2 + \beta^2$, $\alpha_0 = 2\gamma_0$, and β is the angular separation between the position of the deflector and that of the source in the absence of light deflection ($\beta = 0$ for perfect alignment). The corresponding magnitude change is $\Delta m = 2.5 \log A$. The angular position of the primary image with respect to the deflector is given by $\alpha_* = \frac{1}{2}(\alpha + \beta)$ so that the position of the image is apparently shifted by the angle $\delta = \alpha_* - \beta = (\alpha - \beta)/2$. Defining a characteristic transit time T as the time during which the magnitude of the image m_* satisfies $m - \Delta m/2 \leq m_* \leq m + \Delta m/2$, m being the unlensed magnitude, we find $T = 2(\beta_{1/2}^2 - \beta^2)^{1/2} \mu^{-1} \text{ yr}$ where $\beta_{1/2}$ is the value of β corresponding to a change $\Delta m/2$ and μ is the net angular velocity of the deflecting mass, including proper motion μ_0 and parallax π (in arc s yr⁻¹ if β is in arc s).

Given a plate limit m_{lim} , the probability P of observing an angular displacement of magnitude $\geq \delta$ or equivalently a change in magnitude $\geq \Delta m$ can be computed by summing the separate contributions P_m corresponding to background stars of magnitude m , $P_m = 2\beta\mu A_m(60)^{-4} \text{ yr}^{-1}$, where A_m is the number of stars¹³ per square degree in the visual magnitude range $m \pm \frac{1}{2}$ and β and μ are expressed in arc s and arc s yr⁻¹, respectively (the summation $P = \sum P_m$ formally extends to ∞ ; however, for stars with $m > m_{\text{lim}}$, the required change in magnitude is not Δm but $\Delta m + (m - m_{\text{lim}})$, thus giving an observable change of Δm).

Keeping all other parameters constant (such as the magnitude and direction of the tangential velocity), the various quantities scale with the mass as follows: $\pi = c_1 M^{-1/2}$, $\mu_0 = c_2 M^{-1/2}$ and hence $\mu = c_3 M^{-1/2}$, $P = c_4 M^{-1/4}$ and $T = c_5 M^{3/4}$, where the c 's are all constant. The quantity $N = PT$ where $\bar{T}$ is an average transit time (stars with $m > m_{\text{lim}}$ have a shorter transit time with a lower probability of occurrence) is entirely independent of μ and scales as $M^{1/2}$. It is a measure of the number of days in a year where gravitational lensing is in progress. (We can interpret a value of N larger than 365 as meaning that a number of order $N/365$ lensings are occurring simultaneously.)

The results of the calculations are shown in Table 1 and Fig. 2 for a $1 M_\odot$ object. The chosen net angular velocity $\mu = 550 \text{ arc s yr}^{-1}$ has the same value as the proper motion of a $1 M_\odot$ object having a tangential velocity of 10 km s^{-1} . (Its annual parallax would be 250 arc s .) These results are easily generalised to different values of the parameters by using the appropriate scaling laws.

Table 1 shows that the angular shift is a much more noticeable effect than the accompanying brightening up. For a $1 M_\odot$ object, it is also clear from Fig. 1 that, unless $m_{\text{lim}} \geq 21$, one does not expect numerous lensings giving a deflection of more than 1 arc s

Table 1 Typical parameters characterising the gravitational lens effect of a nearby $1 M_\odot$ object having net angular velocity $\mu = 550 \text{ arc s yr}^{-1}$

Δm	0.0002	0.001	0.01	0.05	0.1	0.5	1.0	2.0
α_* (arc s)	12.6	8.44	4.75	3.19	2.70	1.89	1.67	1.53
β (arc s)	12.4	8.18	4.30	2.51	1.90	0.74	0.37	1.27
δ (arc s)	0.17	0.26	0.46	0.68	0.80	1.15	1.29	1.41
T (d)	10.40	6.96	3.90	2.56	2.12	1.20	0.82	0.46

See text for scaling laws.

or $\Delta m \approx 0.1$. However, the probability of observing a deflection of order 0.4 arc s (not an unreasonable value) rises to 0.8, 7, 35 and 140 per yr for limiting plate magnitudes of respectively 15, 18, 21 and 24, each transit lasting about 4 d. Hence, a $1 M_\odot$ object would be detected by (say) taking four or more plates down to $m_{\text{lim}} = 21$ at intervals of three nights.

As for a $150 M_\odot$ BH (hypothetical 3U1832-23 case), a deflection $\delta \geq 0.5 \text{ arc s}$ (corresponding to $\delta_1 \approx 0.14 \text{ arc s}$ on Fig. 2) should be observable roughly 0.6, 6, 30 and 120 times per yr for $m_{\text{lim}} = 15, 18, 21$ and 24, respectively, the transit time now being of order 515 d (about 1.4 yr). Note that the probability (transit time) increases (decreases) by a factor of 10 if we allow a tangential velocity of the order 100 km s^{-1} . On the other hand, a NS or primordial BH of $0.3 M_\odot$ will produce a deflection of the order 0.4 arc s a number of 0.8, 8, 35 and 135 times per yr with a transit time of only 1.4 d.

It should be pointed out here that all calculations are based on mean (with respect to galactic latitude) values for A_m , thus underestimating its value on the galactic plane and hence the probabilities by a factor of the order 3-4. And, of course, if the presumed compact object is brighter than the limiting magnitude, its proper motion alone will make it conspicuous.

Fig. 2 The quantity $N_1/2$ and probability P_1 of observing a gravitational deflection greater than or of the order δ_1 for a $1 M_\odot$ object (hence the subscript) having net angular velocity $\mu = 550 \text{ arc s yr}^{-1}$. The corresponding quantities for other masses, other parameters being the same are given by $P = P_1(M/M_\odot)^{-1/4}$, $N = N_1(M/M_\odot)^{1/2}$ and $\delta = \delta_1(M/M_\odot)^{1/4}$ (strictly speaking P_1 is the expected number of lensings per year).

In conclusion, a temporary companion to our Sun in the form of a NS or a BH could have remained undetected until now. Constraints can be placed, however, on the allowed type of spectrum and/or mass and velocity ranges accessible. In particular, if $n_0 = 1 \text{ cm}^{-3}$ and if the magnetic field plays an important part, we can almost certainly rule out any BH which has $M > 1 M_\odot$ and $v < 100 \text{ km s}^{-1}$. On the other hand, if an encounter with a compact NS or BH is in progress, it could be possible to observe the gravitational lens effect, especially if one knew more precisely in which direction to look. Perhaps some photographic observations of the error boxes associated with the eight aforementioned Uhuru sources would be worthwhile, starting with 3U1832-23. At worst the data obtained could be useful for alternative work such as variable star or proper motion survey; at best, one will have the satisfaction of having observed the (most likely) closest compact object.

Evidence for long-period global oscillations of the Sun

THE results of our observations of the solar potassium resonance absorption line at $7,699 \text{ \AA}$ using integrated solar light from the McMath telescope at Kitt Peak together with an atomic beam resonance scattering apparatus are reported here. In two long runs on successive days we observed wavelength oscillations of large amplitude with a period close to 160 min. If, as we believe, these oscillations are produced by motions of the photosphere, they provide evidence for oscillations of the entire Sun. We describe our experimental method, the analysis of the observations, and the results we obtain, and compare these with previous results.

Resonance scattering of light from a beam of free atoms is an ideal technique for making precise absolute measurements of the shift in wavelength of the light relative to the reference wavelength of the beam atoms. We have used this technique previously to measure the solar gravitational redshift¹ and to observe the 5-min radial oscillation of small regions of the photosphere². We give here only a brief outline of the method as modified for our present observations.

Flat mirrors placed in the main beam of the McMath telescope directed integrated sunlight vertically downwards into our apparatus, where it passed through a $3/16''$ entrance aperture, a $7,699\text{-\AA}$ interference filter with a $16\text{-\AA}$ FWHM and a motor-driven circular polariser unit which alternated the sense of circular polarisation at a frequency of about 23 Hz. The light then passed through a lens and the upper pole piece of a variable-field permanent magnet into a vacuum chamber placed

between the magnet poles where it was focused on a horizontal beam of potassium atoms produced in a nearby oven. Unscattered light was absorbed in a blackened tube placed below the beam while light resonantly scattered in a direction perpendicular to the beam passed through a short horizontal fibre optics light pipe to a dry-ice-cooled photomultiplier tube. The magnetic field was set at its maximum value, roughly 1,800 G, to produce a Zeeman splitting of the beam atom resonance absorption line into two lines whose wavelengths corresponded to the steeply sloping sides of the integrated solar potassium line. The two opposite senses of circular polarisation of the input light produced resonance scattering by beam atoms at these two different wavelengths, so that the system switched back and forth between opposite sides of the solar line at a frequency of 23 Hz. For small wavelength shifts of the solar line, the amplitude of the photomultiplier output signal at 23 Hz was proportional to the shift. This signal was fed to a Keithley 417 picoammeter whose output went to a Keithley 822 phase-sensitive detector (PSD) provided with a 23-Hz reference signal from the circular polariser unit. The d.c. output of the PSD was measured by a Keithley 172 digital multimeter and recorded by a Keithley 750 printer.

We incorporated several features designed to eliminate possible slow variations in the telescope alignment and instrumental effects. First, we diverted light from around the entrance aperture to an image-forming system so arranged that when the image was kept accurately fixed in position by photoelectric guiders the direction of the integrated light entering the aperture was also kept fixed. Second, we continuously monitored on a chart recorder the average value of the picoammeter output signal corresponding to the average of the scattered light intensity from both sides of the solar line as well as the stray light scattered from the walls of the vacuum chamber. At intervals we recorded this signal with the potassium beam turned off, to measure the stray light alone. Third, at intervals we recorded the PSD output with the beam turned off, to measure instrumental effects such as polariser asymmetry.

Our observations were made on 13 and 14 June 1977; we report here only those made during the same continuous time interval on both days. The PSD time constant was 10 s and in our data analysis we used recorded PSD outputs at 1:85-min intervals. After subtracting from each PSD output value the value with atomic beam off and then normalising it using the net beam-on minus beam-off average picoammeter output, we carried out a least-squares fit of the resulting data to the known variation of wavelength with time produced by the Earth's motion. This known variation was used to calibrate our apparatus. Finally, we averaged the residuals in groups of eight, corresponding to a time interval of 14.8 min, and plotted them in Figs 1 and 2.

Fig. 1 Residual wavelength variations of the solar potassium absorption line at $7,699 \text{ \AA}$ using integrated light. Each point is the average of eight residuals over a 14.8-min period. The dashed sine curve has a period of 160 min and its first peak occurs at 20 58 UT. The expected location of a peak, based on the data of Kotov *et al.* lies in the range indicated by the two arrows. A positive residual corresponds to ascending motion on the Sun.

Fig. 2 The dashed sine curve has its peak at 21.10 UT. See legend to Fig. 1 for further details.

At the start of both runs the data seem to scatter randomly. Regular variations then appear with considerably greater amplitude than the noise. Kotov *et al.*³ have presented evidence for periodic variations in the wavelength of an iron line at 5,124 Å, with several different periods, one of which is 160.004 min and has an associated amplitude of about 1 m s^{-1} . These variations remained in phase over a three-year period from 1974 to 1976 and were consistent with the more limited observations of Brookes *et al.*⁴ on the potassium line with a technique similar to ours. Figures 1 and 2 show 160-min sine curves fitted by eye to our data: 160 min is apparently very closely the proper period, but the locations of the peaks only roughly agree with the expected locations based on our extrapolation of the data of Kotov *et al.* which lie in the ranges indicated on the figures by double arrows. (To make this extrapolation we assumed that a peak occurred between 4 h 47.5 min and 5 h 7.5 min UT on 4 August 1974, and that the oscillation period was 160.004 min. See Fig. 6 of ref. 3. If the period is actually 160 min then nine complete oscillations will occupy exactly 24 h so that on successive days the peaks should occur at the same times. We observed a peak on 14 June at 21.10 UT, which is 12 min later than the peak at 20.58 UT on 13 June. A possible explanation is that the period of oscillation of the potassium line is 161.3 min. This would link our data on the two successive days very nicely as well as fitting the data even better.

The power spectra calculated for these two runs showed enhanced power in the range of long periods and also other peaks but we do not trust the results because of the limited amount of data available. It seems that when there are large oscillations, obviously present in a data string, such an analysis is not very useful and is difficult to justify, particularly when each run is only three oscillation periods long. Furthermore, we are wary of attaching too great a significance to the specific periods associated with peaks in the power spectrum as the periods for which power is calculated are determined by the total data string length and are widely separated.

We believe that our method of data analysis has eliminated possible instrumental variations as the cause of the observed wavelength oscillations. We do not see how variations in the Earth's atmosphere could cause such an effect and we conclude

that we have observed a solar effect associated with global oscillation. The large amplitude of the oscillation relative to that observed by Kotov *et al.* as well as the apparent difference in phase still require explanation. Detailed discussion of the expected oscillation periods according to various solar models can be found in ref. 3 and other references listed there.

We are all visiting Astronomers, Kitt Peak National Observatory, operated by the Association of Universities for Research in Astronomy, Inc., under contract with the NSF. We thank the Research Corporation for support.

Measurement of ^{10}Be in 1,000- and 5,000-year-old Antarctic ice

MEASUREMENT of radionuclides by nuclear accelerator spectrometry may lead to wider application of measurement of long-lived cosmogenic isotopes to archaeological, geophysical and astrophysical problems (see ref. 1 for further details of the technique). We previously² discussed the prospects for the isotope ^{10}Be and reported the successful measurement of this isotope using both the internal² and the external³ ion sources of the Grenoble cyclotron. ^{10}Be (half life = 1.5×10^6 yr; ref. 4) is formed by the interaction of cosmic rays with the Earth's atmosphere, and then precipitated out into various geophysical reservoirs such as marine sediments and polar ice⁵. The ^{10}Be profile in these reservoirs can thus be used to search for evidence of historical variations in parameters (geomagnetic field, solar modulation, primary cosmic ray intensity) which influence the deposition rate. We report here the use of the accelerator technique for the determination of ^{10}Be concentrations in samples of Antarctic ice believed to be about 1,000 and 5,000 yr old. The only published measurement for ^{10}Be in polar deposits is that of McCorkell *et al.*⁶ who made their measurement on a sample extracted from 1.2×10^6 l of Greenland ice. The present measurements were made on samples from 10 l. We believe this difference is indicative of the tremendous potential that is offered by the accelerator technique.

The samples studied were taken by a group from the Laboratoire de Glaciologie de Grenoble during the recent successful recovery of a 900-m ice core at Dome C in East Antarctica⁷. During the coring operation, a certain amount of meltwater occurs. This water was recovered and passed through cation exchange resin in the form of resin impregnated filters (Acropor SA-6404, Gelman). The resins were changed at regular intervals. Two of the cation disks were used for the present investigation. The depth and quantity of water to which they were exposed are given in Table 1.

Be was extracted from the resins by soaking them in 3M HCl for several hours (a test with ^7Be confirmed that 100% extraction was obtained in these conditions). A standardised carrier solution, containing ~4 mg of ^9Be was then added to the HCl. The mixture was neutralised and the precipitate of $\text{Be}(\text{OH})_2$ converted to BeO by heating. Pellets of sintered BeO were then fabricated by the procedure described in ref. 2 for introduction into the cyclotron ion source.

The experimental procedure was basically that described in ref. 3 using the external ion source of the cyclotron. Several of the improvements discussed in ref. 3 have been implemented,

Table 1 ^{10}Be determinations and sample details

Sample	Depth (m)	Estimated age* (yr BP)	Vol. of water (l)	$^{10}\text{Be}/^9\text{Be}^\dagger$ ($\times 10^{-13}$)	^{10}Be ($\times 10^4$ atoms per g ice)
RD-14	70.9–75.7	1,000	11.2	7.6 ± 2.5	2.00 ± 0.67
RD-18	235–242	5,000	10.2	11.2 ± 2.8	3.22 ± 0.81
Standard‡	—	—	—	8.1 ± 1.9	—

* Ages are preliminary estimates based on model calculations (C. Lorius, personal communication).

† These ratios are normalised to known standard having $^{10}\text{Be}/^9\text{Be} = 8.24 \times 10^{-12}$.

‡ This standard has a known ratio of 8.30×10^{-13} .

including replacement of the single Si detector by a $\Delta E(8\mu\text{m})$ -E telescope, a 'live-time' clock to take into account high voltage breakdowns, and rapid switching between ^9Be and ^{10}Be at the source by means of changing the extraction voltage rather than the magnetic field. In addition all beam lines have been tuned initially using $^{10}\text{B}^{2+}$ rather than $^{20}\text{Ne}^{4+}$ and this has resulted in an improved transmission efficiency. The most important change was use of a significantly more intense ($\sim 3\mu\text{A}$) output from the ion source. A more detailed description of these modifications will be given elsewhere. For the present discussion the most important effect was that we were able to improve our sensitivity by about two orders of magnitude compared to ref. 3 and so measure samples with $^{10}\text{Be}/^9\text{Be}$ ratios as small as 10^{-12} .

The analysis of the ice samples was made by comparing their $^{10}\text{Be}/^9\text{Be}$ ratio to those of standardised $^{10}\text{Be}/^9\text{Be}$ samples prepared by the method outlined in ref. 2. To avoid contamination problems measurements were made on a 'clean' ion source in the following order; standard ($^{10}\text{Be}/^9\text{Be} = 8.30 \times 10^{-13}$), ice samples, standard ($^{10}\text{Be}/^9\text{Be} = 8.24 \times 10^{-12}$). Each measurement included 20 min of ^{10}Be counting, with the ^9Be current being recorded every 5 min. A blank run gave no counts in 10 min which is equivalent to a background of less than 10% of the ice samples.

Knowing the $^{10}\text{Be}/^9\text{Be}$ ratio and the quantity of ^9Be added initially, we obtain directly the number of ^{10}Be atoms in the original sample. It is interesting to note that the chemical yield of our processing treatment does not enter into such a calculation since we are at all times working with isotope ratios. Also, as our standards have been determined by a mass spectrometric measurement², even the uncertainty associated with the ^{10}Be half-life does not intervene. On the other hand, one assumption we have been forced to make is that all the ^{10}Be initially in the meltwater has been recovered in the resin. Because of the well known tendency of carrier-free Be to hydrolyse in neutral solution and adsorb on container surfaces, this assumption needs to be verified. We hope to be able to do this in the future by measuring the ^{10}Be taken directly from an equivalent quantity of ice in the same core.

The results of our measurements are summarised in Table 1. As the ^{10}Be count rates for the ice samples were 1 to 2 c.p.m., the uncertainties are dominated by statistics. We point out, however, that this limitation in the present circumstances was due to the lack of accelerator time and not to running out of sample. In fact by weighing our samples before and after we were able to estimate that they were consumed at the rate of $\sim 0.05\text{ mg min}^{-1}$.

The present experiment is a prelude to a more general project for measuring complete ^{10}Be 'profiles' in polar ice and marine sediment cores, in order to investigate possible ^{10}Be variations with time and their eventual implications. In fact, the two ice samples in Table 1 do have a concentration difference (which is, however, not statistically very significant). It is tempting to attribute this to the difference in geomagnetic field at the two epochs. It is generally believed that the intensity of this field 5,000 yr ago was only about half of that 1,000 yr ago⁸, and thus ^{10}Be production would be expected to be enhanced at the earlier period. Indeed, this was the reason for choosing the samples

from these periods. However, in view of the limited precision of the present measurements and the fact that we are dealing with only two samples, we content ourselves for the moment with simply taking the mean of the two results as representing a long-term average for the ^{10}Be deposition rate at the site tested.

Using an estimated annual precipitation rate of 3.7 cm of water at the site of our samples (R. Delmas, personal communication), our average ^{10}Be concentration (2.6×10^4 atoms per g ice) represents a ^{10}Be deposition rate of 3.1×10^{-3} atoms $\text{cm}^{-2} \text{s}^{-1}$. This is much less than the value $2.0(+0.9 \text{ or } -0.5) \times 10^{-2}$ atoms $\text{cm}^{-2} \text{s}^{-1}$ (recalculated using the currently accepted half life⁴) measured at the Greenland site⁶. It is also 4 to 8 times smaller than the deposition rates found in most sea sediments^{9–11}. There are two possible explanations for a low ^{10}Be deposition rate at the site of our samples. First, based on measurements from bomb tests in the stratosphere, it is expected that deposition of long-lived cosmogenic isotopes at high latitudes should be substantially less than the world average⁵. In this respect, it is perhaps significant that our rate is consistent with the upper limits for the only sediment results at high latitudes¹². (Although, depending on the ^{10}Be ocean residence time, one might or might not expect such variations to be largely washed out in marine sediments due to ocean mixing.) Such an explanation would, of course, leave the Greenland⁶ result difficult to understand. Second, it is also expected that, at a given latitude, fallout rates will be roughly proportional to precipitation⁵. It will clearly be interesting to make measurements on ice samples from the coastal regions of Antarctica, where the precipitation rate is about an order of magnitude greater than at the site of the present samples, in order to determine which of these effects is dominant.

The primary objective of this study was to test whether ^{10}Be concentrations of the required sensitivity could be measured in the available ice cores (the $\sim 10^4$ atoms of ^{10}Be in each sample is several orders of magnitude smaller than could be measured by traditional beta counting, as discussed in ref. 2). In this respect the experiment was a complete success. We are thus optimistic about the chances of being able to make a complete ^{10}Be profile over the entire length of the core from which the present samples were taken (estimated to go back to 35,000 BP). If the ^{10}Be production should be as sensitive to geomagnetic field as hinted at in the present results, such a profile would offer an unparalleled opportunity for tracing the intensity variations of this field over that period. It would also allow one to look for effects such as the Laschamps–Lake Mungo–Malefif 'events'^{8,13}, which may or may not be correlated with each other and/or with worldwide dipole variations.

The present ^{10}Be determinations in samples that were unmeasured (and unmeasurable) by any other existing technique, moves accelerator spectrometry out of the phase of exploration and into that of exploitation.

We thank C. Lorius and his group for their cooperation, in particular R. Delmas who suggested use of the resin samples. We thank J. C. Ravel for assistance with the ion source.

Creep rupture at depth in a cold ice sheet

THE mechanism by which stress is released in intermediate and deep focus earthquakes and the physics of tectonic processes are of particular interest to Earth scientists. As a way of understanding such phenomena it would be valuable to have a relatively small scale tectonic system duplicating the processes taking place within the Earth. Several authors^{1–3} have speculated that processes operating within glaciers and ice sheets are analogous to those in the Earth. Experimental evidence has not supported the hypothesis of an Earth glacier equivalence, especially in terms of identifying faulting at depth within glaciers. A seismic survey made of a valley glacier in Canada⁴ found no deep ice events. However, evidence of the existence of discrete shear planes within the Antarctic Ice Sheet⁵ and evidence described here relating to the Greenland Ice Sheet, indicate that faulting takes place at depth in cold ice sheets.

At great depths beneath the surface of the Earth (500–700 km) where the pressure is of the order of 10^{10} Pa and high homologous temperatures prevail, classical laws of brittle failure do not apply. As an alternative to stress release by brittle fracture, rupture of the material may result when creep is concentrated in very narrow bands subjected to shear stresses. Consideration of the creep rupture phenomenon and its associated stress drop have led to some current models of fault mechanisms for earthquakes⁶.

The mechanism by which stress is released in intermediate and deep focus earthquakes is of particular interest to seismologists and tectonophysicists. Orowan¹ proposed that faulting at depth is initiated by the development of creep instabilities in shear layers in the Earth. The stress drop theory associated with Orowan's faulting mechanism serves as a partial base for models describing the seismic spectra from earthquakes.⁶ To verify his theory, Orowan¹ proposed that this faulting mechanism might also operate in temperate glaciers.

As a means of verifying the creep-rupture theory, Neave and Savage⁴ carried out a seismic investigation on the Athabasca Glacier in Canada. They aimed to detect shear faulting at depth within the glacier. After 390 h of seismic monitoring they concluded that creep instabilities which would be recorded as deep focus ice-quakes had not taken place in the Athabasca Glacier.

Field investigation of glaciers are generally conducted where simple flow regimes occur, so that research findings can be generalised^{7–9}. However, recent drilling at the margin of the Greenland Ice Sheet^{10,11} in a peculiar area characterised by upslope flow of cold ice over geometrically complicated bedrock (see Fig. 1), has revealed the presence of a fracture at 240 m depth in the ice. The evidence for the fracture is threefold. First, although drilling was temporarily stopped at 250 m depth surface meltwater was observed to enter the liquid-filled hole, thus showing that the drilling fluid was running out of the hole at some depth. As no crevasses, moulins or englacial conduits are present in this area, this behaviour can only indicate the existence of an open fracture that intersects the hole between the surface and 250 m depth. The hole was then completed to bedrock at 299 m. Second, following drilling the saltwater used as a drill fluid was spontaneously flushed from the upper 240 m of the hole by surface meltwater whereas the lower 59 m of the hole retained the salty water, as shown by temperature measurements made periodically after the completion of drilling¹⁰. Third, calculated temperature profiles¹² for four other

holes in the same area are in excellent agreement with measured temperatures, but the calculated profile for the hole in question agrees equally well with the measured temperatures only if the ice is assumed to flow over an area of 'dead ice' as shown in the Fig. 1. Direct observations of dead ice have been made in valley glaciers but not in cold ice sheets.

As no evidence of a pre-existing fracture was obtained, it is possible that the excess hydrostatic pressure of the drilling fluid ($\sim 2.4 \times 10^5$ Pa) and the flow shear stress caused the formation of the fracture along a zone of weakness between the dead and moving ice. Whether or not there was a pre-existing fault at this depth, the excess hydrostatic pressure caused propagation and opening of the fracture sufficient to accept a large quantity of water; hence, it is likely that the fracture propagated to bedrock around the area of dead ice (the subglacial tills are permeable in this area¹⁰). The small excess hydrostatic pressure could not have caused fracture without an existing zone of creep-enhanced weakening at this depth.

Fig. 1 Ice thickness and bedrock profile (from a seismic survey) is shown along the flow line through the drill hole, Isua, Greenland.

The geometry shown in Fig. 1 suggests an area of dead ice overridden by the ice sheet while temperature and water flow observations clearly show a fracture in the ice at 59 m above the bed. This evidence for fracture at depth in the Greenland Ice Sheet leads us to reconsider the correspondence between flow and rupture at depth in the Earth and in cold ice sheets as suggested earlier^{1,2}. If seismic evidence of deep fracturing in cold ice sheets is found we will have a large-scale tectonic system available for the study of deep fractures associated with the underthrusting of cold lithospheric plates¹³. Direct investigations at depth in ice sheets are made with relative ease as compared to the nearly impossible task of direct measurements in the Earth's mantle.

Loss of fixed nitrogen from soils by nitric oxide exhalation

LABORATORY studies¹⁻⁸ have indicated that chemical denitrification processes in nitrogen rich soils and nitrite solutions can produce NO or NO₂ and perhaps methyl nitrite⁹. It has been suggested¹⁻⁶ that self decomposition of nitrite produces various gaseous nitrogen compounds including nitric oxide (NO) and it was thought that NO was unlikely to escape from the soil because in aerobic soils NO is readily oxidised by molecular oxygen to NO₂ and this in turn is rapidly adsorbed by soil materials and by soil water^{1,2}. However the half life of oxidation is dependent on the NO concentration because it is a termolecular reaction^{10,11}. At concentrations of 100 p.p.m. or greater (as in some studies) the half life for oxidation of NO to NO₂ by atmospheric oxygen is one hour or less respectively, whereas at low concentrations (~0.01 p.p.m.) the half life for this oxidation is of the order of 10⁴ h. This variation in the oxidation rate by molecular oxygen explains why NO at low concentrations in the field can pass unoxidised from the soil to the atmosphere and perhaps explains why in some of the laboratory studies (at high concentrations) NO₂ and not NO is detected. This NO exhalation in the field could not be detected previously due to the lack of a sufficiently sensitive measurement technique. We report here the first measurements indicating that NO is continuously exhaled from soils including ungrazed, unfertilised grassland. The measured rates of exhalation from the soil to the atmosphere are 0.06 to 0.73 × 10⁻¹¹ kg nitrogen m⁻² s⁻¹ (equivalent to 0.2 to 2.3 kg N ha⁻¹ yr⁻¹). We show that this exhalation of NO is a significant source of nitrogen oxides (NO_x) in the lower atmosphere as has been previously suggested^{12,13}. These nitrogen oxides exert a direct influence on the ambient ozone and hydroxyl radical concentrations¹⁴ which in turn pre-

Fig. 1 Exhalation of nitrogen oxides at Aspendale on 26.11.76. The time zero corresponds to the moment of placing the box over the soil surface. ○, ambient NO_x; ◇, ambient NO; ●, box NO_x; ◆, box NO.

ester film (Dupont) to prevent gas uptake on the box walls and stirred by a 0.2 m diameter stainless steel fan driven by an external electric motor. The method will be described in detail elsewhere. NO and NO_x measurements were made with a sensitive chemiluminescent NO detector¹⁶. The NO_x measurement, (obtained by diverting the sample flow through a commercial molybdenum converter) gives the total gaseous concentration of NO, NO₂, alkyl nitrites and nitrates and peroxyacetylnitrate. These are accepted methods for measuring low concentrations of nitrogen oxides in ambient air^{18,19}.

Measurements were made at three locations described briefly in Table 1 and in more detail elsewhere²⁰⁻²². The range of conditions covered included before and after rain, day and night and spring and autumn. On every occasion measurable exhalation was found. In all experiments there was no significant difference between the concentration of NO and NO_x in the box, indicating that NO is the dominant species exhaled from the soils studied.

Kim²⁴ measured NO₂ liberation from forest soils in Korea with a closed system consisting of a sealed plastic hood containing 0.01 M sodium hydroxide absorbent. The sodium hydroxide solution used by Kim also collects NO rather inefficiently²⁵ and his results, therefore, possibly need reconsideration. Also the presence of this absorbent can inhibit autotrophic nitrification of ammonium by removing carbon dioxide²⁶.

A typical set of results is shown in Fig. 1. Immediately after placing the box over the surface there was a monotonic increase in the NO in the box above ambient levels. Generally, the concentration in the box gradually approached a maximum or equilibrium value. This behaviour indicates that there is some competing uptake mechanism or back-reaction that, in conjunction with the exhalation process, regulates the concen-

Table 1 Description of experimental sites

Location	Land usage	Soil description ²³	Nitrogen fertiliser usage

dominantly determine the oxidation rate of almost all substances in the troposphere.

We determined the NO and NO_x flux from various soil surfaces by placing an open-ended box over the soil and measuring the rate of increase in concentration of these gases in the box during the following few minutes. It is assumed that the presence of the box during this time did not impede or exaggerate the gaseous flux from the soil. The continuing increase of NO in the box after sampling is discontinued indicates that there is no artificial pressure-induced exhalation of soil air into the box. The box, similar to that described elsewhere¹⁵, was a perspex cube (0.8 m per side), internally lined with Mylar poly-

Table 2 Soil analyses at Conargo sites

Site	Soil moisture (%)	Soil pH	NO ₃ -N p.p.m.	NH ₄ -N p.p.m.
1	18.6	7.6	2.1	4.0
2	10.7	6.5	1.3	3.8
3	12.2	7.2	13.1	2.4

tration of NO in the box bringing it into equilibrium with the soil/soil-atmosphere system. Concentrations of NO greater than the equilibrium value were artificially injected into the box on some occasions. The NO concentration then always decreased back to the same equilibrium value for the site.

The soil analyses presented in Table 2 (made at the time of the exhalation experiments) show that the mechanism for NO production in soil operates at a soil pH near 7 and at the p.p.m. nitrate-N and ammonium-N levels. Analyses performed recently show similar concentrations at the Aspendale site; these analyses also showed less than 0.2 p.p.m. nitrite-N. Nitrite analyses were not performed at the time of the experiments. Our results confirm laboratory experiments^{3-5,8} where detection of volatilisation products as either NO or NO₂ occurred for neutral and slightly alkaline as well as for acidic soils.

Our experimental data and the calculated emission rates are shown in Table 3. If the average flux of $0.3 \times 10^{-11} \text{ kg N m}^{-2} \text{ s}^{-1}$ is integrated over a year then a figure of $1 \text{ kg N ha}^{-1} \text{ yr}^{-1}$ is obtained.

The fluxes observed for ungrazed and grazed pastures are 0.16 and $0.35 \times 10^{-11} \text{ kg m}^{-2} \text{ s}^{-1}$ respectively. If these are representative of globally averaged land emission rates then a

global annual value of the order of $10^{10} \text{ kg N yr}^{-1}$ is obtained which can then be compared to the global nitrogen fixation rate of 2 to $3 \times 10^{11} \text{ kg N yr}^{-1}$ (ref. 27). The loss of NO from the soil is not a permanent loss of fixed nitrogen as this nitrogen is most probably returned to the soil as nitrates in rainwater. Thus NO exhalation may be a significant process in redistributing fixed nitrogen throughout the global biosphere.

In the Northern Hemisphere troposphere these annual emissions may be $0.8 \times 10^{10} \text{ kg N}$ which, with the anthropogenic NO_x sources of $1.5 \times 10^{10} \text{ kg N}$, are sufficient to account for the nitrate deposition in rainwater of $2 \times 10^{10} \text{ kg N}$ (ref. 13).

The emissions reported here are, per unit area, about 40 times larger than the depositions of NO₃ nitrogen reported for Antarctic ice by Parker *et al.*^{28,29}. We suggest the NO₃ nitrogen in Antarctic ice may result from the long range transport of fixed nitrogen from the continental regions of the Southern Hemisphere.

We thank the CSIRO Riverina Laboratory for making the Conargo site and facilities available and Drs D. Tongway and J. R. Freney for the soil analyses.

Coaxial pure shear in Jamaican blueschists and deformation associated with subduction

A RECENT report of deformation features in high pressure-low temperature blueschists on the Ile de Groix, France, has demonstrated that the style of deformation is one of progressive, non-coaxial simple shear¹. I present here evidence that the blueschists in Jamaica underwent a coaxial pure shear deformation contemporaneous with metamorphism and suggest that simple shear deformation in blueschists is no more compatible with subduction than any other deformation style. I suggest that domains of relatively homogeneous deformation occupying tens of km³ may develop in subduction complexes.

Metamorphic rocks in Jamaica consist of a narrow, NW-SE trending belt of metagreywackes and metabasites metamorphosed in blueschist, greenschist and amphibolite facies conditions^{2,3}. The belt is situated along the southern edge of the Blue Mountain massif in eastern Jamaica and the blueschists lie at the eastern end of the belt about 30 km ENE of the city of Kingston (for exact location see ref. 3). The metamorphism was the result of subduction which probably occurred in the late Cretaceous^{2,3}, but the only isotopic ages available are from biotite and hornblende in the amphibolite facies rocks⁴. The blue amphibole crossite occurs in the eastern extremity of the belt and is associated with pumpellyite, stilpnomelane, albite, clinozoisite and sphene. All CaCO₃ identified so far is calcite. Lawsonite does not seem to occur, either because the pressure/temperature gradient was not sufficiently high or because of high CO₂ pressure during metamorphism⁵. Some rocks are not entirely recrystallised and contain relict igneous augite.

The blueschists typically show an L-S tectonic fabric which plunges approximately 30° to the NNW. This orientation is not

Fig. 1 Logarithmic strain plot of finite strains (ϵ) from L-S tectonites of Jamaican blueschist terrain. Most fall in the field of constriction.

consistent because the rocks have undergone further deformation associated with Tertiary E-W left lateral motion on the northern Caribbean plate boundary which lies to the north of Jamaica. The lineation itself is due to stretching parallel to the x-axis of the finite strain ellipsoid. Ellipsoidal, microcrystalline sphene blebs are probably derived from alteration of original ilmenite. A statistical study of these in individual specimens^{6,7} provides finite strain estimates, most of which fall in the field of constriction of Fig. 1.

Evidence for the coaxial nature of the strain history is exhibited by the relict augites which have undergone paracrystalline microboudinage. Amphibole fibres which have grown epitaxially between boudins are zoned continuously from riebeckitic actinolite to crossite (Fig. 2). The x-axis of the finite strain ellipsoid, amphibole fibres and elongation as defined by the boudinage are all parallel. These textural features are not unique to Jamaica and have been reported from Washington, US^{8,9}.

With continuing strain either the material properties of the rock changed or there was a change in the rate of strain, as further strain was taken up heterogeneously by the formation of discoidal ductile 'fractures' or tears. The planes of the tears are perpendicular or subperpendicular to x and are filled with tremolite and quartz fibres parallel to x. Tears are up to 0.1 m in thickness and 0.4 m in diameter and seem to be distributed randomly through the rock at intervals from a few centimetres to

Fig. 2 Sketch from thin section cut parallel to x-z plane of finite strain ellipsoid, showing typical microboudinage texture developed in metabasites. px, relict augite; g, glaucophane/crossite; a, riebeckitic actinolite; p, pumpellyite; s, ellipsoidal sphene blebs. Scale bar, 1 mm.

tens of centimetres. They have contributed to a further 5–10% extension in the x direction. This pattern of deformation is found throughout the entire blueschist terrain (about 12 km²).

The progressive coaxial pure shear reported here contrasts with the progressive simple shear reported from the Ile de Groix¹. Both these modes of deformation were contemporaneous with high pressure–low temperature metamorphism which most workers believe is produced in the crustal portions of subduction zones^{10,11}. On the megascopic scale the regional pattern of deformation is one of simple shear as the lower plate moves under the upper. However, on a finer scale, deformation is likely to be more heterogeneous. Regimes of simple shear may well exist in the rocks overlying the downgoing plate, but there is no evidence to suggest that they persist throughout the whole accretionary prism. Consideration of the irregularities in the topography of the downgoing oceanic plate and variations in the geometry of the subduction zone along strike suggest that both the simple shear of the Ile de Groix rocks and the pure shear of the Jamaican rocks are special cases and that most syn-metamorphic deformation in blueschist terrains is likely to be heterogeneous at least on a regional scale. The relatively homogeneous but different styles of deformation developed in the Jamaican and Ile de Groix terrains are present in a volume of rock of tens of km³. Do deformation domains on this scale develop in subduction complexes, or is heterogeneity developed on a finer scale in other blueschist terrains? Mechanisms of blueschist emplacement ('obduction') will be equally varied and complex. Thus, many patterns of strain in blueschists may be compatible with subduction and emplacement. More comparative studies are needed before general statements can be made.

I thank Geoff Wadge for his constructive criticism.

Geology, fauna and palaeoenvironments of Lower Sivalik deposits around Ramnagar, India

ALTHOUGH the Sivalik deposits of the Ramnagar basin (Jammu and Kashmir, India) have been known to palaeontologists and palaeoanthropologists for about 100 yr, little has been reported about the fauna, flora and palaeoenvironments of the region. Most reports centre round the primates^{1–2}, and no attempt has been made to report the other vertebrates in detail. We surveyed the Ramnagar area during the field seasons of 1975–77, and catalogued more than 600 fossil specimens representing a diversity of mammals, reptiles and fish, recovered from several localities shown in Fig. 1. We report those finds here.

The Ramnagar sediments contain fauna characteristic of the Chinji Formation of the Lower Sivaliks. These deposits can be correlated biostratigraphically with the Vindobonian of Europe and possibly the Fort Ternan deposits of East Africa³ which have been assigned a potassium-argon date of 12–14 Myr. No radiometric dates are available for the Chinji deposits at Ramnagar but they can be assigned an age equivalent to 11–13 Myr on the basis of their fauna.

Fig. 1 Generalised local-ity map of Ramnagar.

The outcrops at Ramnagar show a remarkable uniformity in lithology. The beds, which are best exposed along streamlets and road cuttings, consist of alternate layers of argillaceous and arenaceous sediments, the latter dominating the former. The

clayey units are greenish to dark pinkish and show evidence of nodular weathering. The sandstones contain a high percentage of undecomposed rock fragments and are frequently cross-bedded. The upper surface of sandstones is marked with asymmetrical ripples and a network of desiccation fissures in many places.

During the survey numerous fossilised fragments of various mammals were collected (Table 1). Detailed descriptions of the fossils are not available and the identifications should be considered provisional, although in broad outline they are likely to stand. In addition to primates a diversity of proboscideans, perissodactyls and artiodactyls were found. No specimen of *Hipparion* was collected and among the rodents, apart from a few rhizomyoids, only a single tooth of a ctenodactylid and a partial skull of a murid were recovered.

The general nature of the sediments is indicative of deposition in a flood-plain. The presence of red and brownish coloration in many rock units suggests that a considerable portion of sediments was deposited in oxidising and possibly warm and humid conditions. Intermittent desiccation is indicated by the occurrence of desiccation fissures on the surface of arenaceous units. The common occurrence of undecomposed rock fragments in sandstones implies short or rapid transportation, which in turn implies deposition of the sediments close to the source area.

The mammalian fossils consist mainly of suids, small artiodactyls and primates. Their abundance provides indirect evidence for the existence of general forested conditions in the vicinity of the depositional basin. The deinotheres and primitive gomphotherids are thought to have lived on soft vegetation and may have inhabited areas adjacent to water bodies and abounding in succulent and fleshy plants. The abundance of tragulids like *Dorcatherium* and *Dorcabune* implies the presence of bushy forest undergrowth near the site of deposition.

Natural source of tetraalkyllead in air

THE biological methylation of inorganic mercury in sediments in both aerobic and anaerobic conditions is well known¹, and attention has focussed on the possibility of a similar process for lead in the environment. It has been possible to methylate lead in laboratory studies, with the resultant evolution of gaseous tetramethyllead²⁻⁴, but there is still considerable doubt as to whether such processes occur in the environment⁵. A report⁶ that tetraalkyllead accounts for 10-24% of the total lead in the liver of fresh and frozen samples of cod and 39% of the total lead in mackerel muscle lends credence to the possibility. However, we can now present firm evidence of a natural source contributing tetraalkyllead to the atmosphere.

Our evidence was obtained from a monitoring programme carried out between August 1977 and January 1978, during which we determined 24-h average concentrations of particulate lead and gaseous tetraalkyllead in duplicated air samples collected on 24 separate days, and 48-h averages obtained on four occasions, at three remote rural sites around Lancaster selected because of their freedom from local vehicular pollution sources. Particulate lead was collected on a 0.45-µm membrane filter (Millipore type HAWP 04700) and determined by flameless atomic absorption spectrometry after extraction into acid solution⁷. Tetraalkyllead was trapped quantitatively downstream of the filter in iodine monochloride solution and the lead concentration was determined by flameless atomic absorption spectrometry after selective extraction into acid solution, by means of a technique specific for tetraalkyllead compounds^{8,9}.

To interpret our results (Table 1) it is necessary to consider the known sources of particulate lead and tetraalkyllead in rural air. Furthermore, while the data can be examined in terms of their absolute concentration, it is of more value to consider the concentrations of tetraalkyllead as a percentage of total lead, as these figures depend less on site characteristics and meteorological conditions and facilitate comparison between data¹⁰. Particulate lead and tetraalkyllead in the atmosphere are due principally to emissions from vehicles fuelled by leaded petrol. These emissions arise predominantly in urban areas. Harrison and Perry¹⁰ have reviewed available data on tetraalkyllead concentrations in these urban source areas (Table 1). High concentrations of tetraalkyllead can develop around petrol stations and in underground car parks, where there is considerable evaporative loss of petrol. However, tetraalkyllead as measured by reliable techniques is more typically present at lower concentrations in urban air, representing only a small proportion of

total lead, usually about 1-4%. We made further measurements of tetraalkyllead in air, finding it to represent 4.5-5.7% of total lead close to a busy street in Lancaster city centre, when an activated carbon trap method was used,¹¹ and 0.22-0.46% of total lead alongside a remote section of the M6 motorway in Cumbria, measured as 24-h averages by the sampling and analytical method⁹. Thus we conclude from the available data that in the absence of a strong local source tetraalkyllead is most likely to represent 1-4% of total lead in urban air with an overall range of 0.5-8%.

Table 1 Concentrations of particulate lead and tetraalkyllead in urban and rural air

	Particulate lead (ng m ⁻³)	Tetra- alkyllead (ng m ⁻³)	Ratio tetra- alkyllead/ total lead (%)	Source
Urban air (typical values)	500-14,500	<6-206	0.3-4	ref. 10
Petrol station	5,500-6,000	210-590	4-10	ref. 10
Underground car park	10,800-12,200	1,800-2,200	15-18	ref. 10
Rural air	10-660	0.5-230	1.5-33	This work

Lead pollution of rural air arises mainly from advection of urban pollution, and the concentrations of particulate lead and tetraalkyllead in rural air due to urban emissions depend on atmospheric dispersion and dilution effects, the distance of the urban source from the rural site, and the extent of losses *en route*. Only the latter, however, affects the relationship between particulate lead and tetraalkyllead concentrations. It is well known that a large proportion of particulate lead emission is within the size range of particles which form a stable aerosol, so that this lead is lost only slowly from the atmosphere, with a mean lifetime probably in the range 1-7 d.¹² We have determined the mechanism of tetraalkyllead breakdown in the atmosphere¹³ and can predict that tetramethyllead, the predominant tetraalkyllead compound in the atmosphere¹⁰, will have a typical mean lifetime of the order of several days. The loss of both particulate lead and tetraalkyllead from the atmosphere will therefore occur at similar rates, with a resultant ratio of tetraalkyllead to total lead predicted for a rural site of close to the original urban value of 1-4%.

Our data, summarised in Table 1, show that there is a significant departure from expected values. The concentration range for particulate lead, as anticipated, lies considerably below that in urban areas, while the range for tetraalkyllead does not differ so greatly. Indeed, the peak rural concentration of 0.23 µg m⁻³ tetraalkyllead is rarely exceeded in street air measurements¹⁰. Furthermore, seven out of the 28 samples

Fig. 1 Time-weighted pollution roses for lead concentrations measured at three rural sites around Lancaster. a, Particulate lead; b, tetraalkyllead; c, percentage ratio tetraalkyllead/total lead.

Fig. 2 Terminal directions of geostrophic backward air mass trajectories for a sample period with a tetraalkyllead/total lead ratio of 1.5%. Time of arrival of air mass: 1, 1800 h 18/10/77; 2, 0000 h 19/10/77; 3, 0600 h 19/10/77; 4, 1200 h 19/10/77.

revealed unusually high tetraalkyllead to total lead percentages, in excess of 15%, with a maximum of 33%. Such high percentages are most unlikely to arise from urban emissions. We therefore examined our data in more detail, to identify any relationship between the concentrations and wind direction during a sampling period. Time-weighted pollution roses were constructed, based on hourly wind direction frequency data at 10 m height, divided into 30° sectors (Fig. 1). These reveal the expected pattern for particulate lead, with evidence of the strong influence of urban emissions to the south and south-east of the

Fig. 3 Terminal directions of geostrophic backward air mass trajectories for sample periods with a tetraalkyllead/total lead ratio in excess of 20%. A, Ratio of tetraalkyllead/total lead = 25%. Time of arrival of air mass: 1, 1200 h 30/8/77; 2, 1800 h 30/8/77; 3, 0000 h 31/8/77; 4, 0600 h 31/8/77. B, Ratio of tetraalkyllead/total lead = 27%. Time of arrival of air mass: 1, 1800 h 16/12/77; 2, 0000 h 17/12/77; 3, 0600 h 17/12/77; 4, 1200 h 17/12/77.

sampling sites (Fig. 1a). The picture that emerges for tetraalkyllead, on the other hand, is far less clear (Fig. 1b). When, however, the data for the percentage of tetraalkyllead in total lead are examined a distinct directional influence is revealed (Fig. 1c). High mean sector values of 10–15% are associated with winds of 180–300°, while lower mean values of 5–6% occur with winds from other quarters. These data indicate that a widespread source of tetraalkyllead emissions lies generally to the west of the sampling sites.

Because wind directions indicate only local low-level air movements, geostrophic backward air mass trajectories have also been constructed at 6-h intervals during selected 24-h sample periods (that is, four trajectories per sample), to show synoptic scale air movements. The lowest individual percentage values measured of about 2% are associated with air which had passed over the urban areas to the south and south-east (Fig. 2).

Fig. 4 Terminal directions of geostrophic backward air mass trajectories for sample periods with a tetraalkyllead/total lead ratio in excess of 20%. C, Ratio of tetraalkyllead/total lead = 21%. Time of arrival of air mass: 1, 1200 h 31/8/77; 2, 1800 h 31/8/77; 3, 0000 h 1/9/77; 4, 0600 h 1/9/77. D, Ratio of tetraalkyllead/total lead = 33%. Time of arrival of air mass: 1, 1800 h 31/10/77; 2, 0000 h 1/11/77; 3, 0600 h 1/11/77; 4, 1200 h 1/11/77.

These values are consistent with those to be expected in an urban plume largely unaffected by losses of either particulate lead or tetraalkyllead. On the other hand, periods during which values exceeded 20% are all associated with air which had passed over open sea and the coastal areas adjacent to the sampling sites (Figs 3 and 4). Further examination of our data leads us to suggest that the source of tetraalkyllead is more likely to be associated with the extensive coastal/estuarine intertidal mud flats to the west of our sampling sites, rather than the open sea. Both seawater and sediments in this region have been shown to have elevated levels of inorganic lead (ref. 14 and S. R. Aston personal communication), presumably arising from estuarine discharges of anthropogenic origin. In our view, this source of tetraalkyllead can only be explained by a natural environmental methylation of lead.

Light-dependent net production of carbon monoxide by plants

PLANTS take up ^{14}CO and incorporate it into organic compounds in the light and in the dark, and it has been suggested that this decreases the concentration of CO polluting the atmosphere^{1,2}. Measurements of ^{14}CO uptake, however, have excluded any concomitant release of CO by the plants and are insufficient for conclusions to be drawn on net CO exchange. Many organisms (microbia, plants, fungi and animals, including man) can produce CO (refs 3-5). We report here that using a Siemens U 180 process gas chromatograph, we have observed a light-dependent net production of CO by intact plant shoots which seems to be linked to photorespiration.

Fig. 1 Dependence of CO (▲) and CO₂ (●) exchange on irradiance. Leaf temperature 28.3 °C; CO concentration in the gas stream supplied to the gas-exchange chamber 2.07 mm³ m⁻³, average CO concentration within the chamber during the experiment 4.78 mm³ m⁻³; CO₂ concentration 250 cm³ m⁻³; O₂ concentration 21 vol %.

In two sets of experiments the shoot of an intact plant of *Nerium oleander* L. with a total leaf surface area of 0.07 m² and 0.18 m², respectively, was sealed in a gas exchange chamber with a volume of 0.01 m³. (A leaf surface of 0.0065 m² is equivalent to 1 g fresh weight. Similar responses are observed with *Vicia faba* L.). Light was obtained from two 400-W HRIL phosphorus-coated metal halide lamps. Various mixtures of gases were passed through the chamber at 30×10^{-6} m³ s⁻¹. Net CO exchange was measured with the gas chromatograph and net CO₂ exchange with an URAS 2T infrared gas analyser. The mixtures were obtained by mixing O₂, N₂, CO₂ and synthetic air from gas cylinders, using dosage pumps and gas flow meters. Traces of CO were removed by passing the gas stream over granulated CO catalyser (Dräger). When required, different concentrations of CO were obtained by adding to the CO-free mixtures various amounts of normal laboratory air whose CO concentration was known from analysis with the gas chromatograph. The atmosphere at our laboratory, at the periphery of the eastern part of Darmstadt, contained up to 3 cm³ m⁻³ CO at peak traffic hours and 0.3 cm³ m⁻³ at other times of the day. This CO caused some problems because of temperature-dependent diffusion of CO into the gas-exchange chamber through small but unavoidable leaks in the apparatus. This diffusion was 1.9 nmol h⁻¹ at 16.6 °C, 3 nmol h⁻¹ at 22.5 °C and 13.8 nmol h⁻¹ at 39.2 °C. Corrections for this contamination were made in calculating net CO production by the plant.

Fig. 2 *a*, Dependence of CO (▲) and CO₂ (●) exchange on O₂ concentration. Leaf temperature 27.5 °C; CO concentration supplied to the gas-exchange chamber 1.61 mm³ m⁻³, average CO concentration within the chamber 4.63 mm³ m⁻³; CO₂ concentration 275 cm³ m⁻³; irradiance 28.0 W m⁻². *b*, Dependence of CO and CO₂ exchange on CO₂ concentration. Leaf temperature 25.5 °C; CO concentration supplied to the gas-exchange chamber 1.9 mm³ m⁻³, average CO concentration within the chamber 4.45 mm³ m⁻³; O₂ concentration 21 vol %; irradiance 35.8 W m⁻².

When the atmosphere in the chamber contained 40–825 mm³ m⁻³ CO the *N. oleander* leaves consistently increased the CO concentration by 10–17 mm³ m⁻³. When the atmosphere contained even 100–120 cm³ m⁻³ CO, plants still did not show a net absorption of CO (ref. 6).

Net production of CO was then studied with low concentrations of CO in the gas stream supplied to the chamber (~2 mm³ m⁻³) and compared with CO₂ gas exchange. CO production was stimulated considerably by light; there seemed to be a small insignificant release of CO in the dark (Fig. 1). Production of CO in the light was increased by increasing the

Fig. 3 Dependence of CO (▲) and CO₂ (●) exchange on air temperature in the gas-exchange chamber. CO concentration supplied to the gas-exchange chamber 2.02 mm³ m⁻³, average CO concentration within the chamber 4.54 mm³ m⁻³; CO₂ concentration 250 cm³ m⁻³; O₂ concentration 21 vol %; irradiance 18.7 W m⁻².

concentration of O_2 and decreased by increasing the concentration of CO_2 in the ambient atmosphere (Fig. 2). Photosynthetic CO_2 fixation showed an inverse relationship to the concentrations of CO_2 and O_2 (Fig. 2). Increasing temperature greatly enhanced CO release (Fig. 3).

As photorespiration responds in a similar way to environmental parameters⁷⁻⁹, these results suggest that light-dependent production of CO is a by-product of photorespiratory C_1 metabolism. CO could be derived from the glycolate pathway of photorespiration in two ways. First, direct oxidative decarboxylation of glycolate may produce formate¹⁰ and hence CO . Second, formate and CO may originate from the tetrahydrofolate activated C_1 unit formed during photorespiratory synthesis of one molecule of serine from two molecules of glycine¹¹. The significance of this minimal production of CO is not clear; nonetheless, the net exchange of CO by plants is a small emission, not absorption.

The gas chromatograph was a gift of the Fritz and Margot Faudi Foundation, Oberursel.

Photorespiratory nitrogen cycle

MOST temperate plants form phosphoglyceric acid as the first stable product of photosynthesis. These plants also photorespire, that is, during CO_2 fixation they simultaneously release CO_2 to the atmosphere from the oxidation of an intermediate of the photosynthetic process^{1,2}. The reaction below, which takes place in the mitochondria^{3,4}, is chiefly responsible for this CO_2 release.

Photorespiration is considered wasteful because it loses CO_2 and energy, but little emphasis has been placed on the simultaneous and stoichiometric release of NH_3 . Based on estimates of photorespiration in wheat leaves of $80 \mu\text{mol } CO_2 \text{ h}^{-1} \text{ g}^{-1}$ fresh weight^{5,6}, NH_3 loss far exceeds the calculated rates of primary NH_3 assimilation from NO_3^- reduction⁷⁻⁹. This NH_3 must be reassimilated if the plant is not to lose all its organic nitrogen. Recent ^{15}N studies show that NH_3 is recycled¹⁰ but it is not known if reassimilation is catalysed by glutamine synthetase (GS), as is primary NH_3 assimilation^{11,12}, or by glutamate dehydrogenase (GDH) also present in the mitochondria^{11,12}. Identification of the pathway is important because it determines the extent to which NH_3 cycling further increases the energy loss caused by photorespiration. We report here experiments which show that reassimilation involves GS and we propose a series of reactions which make up the photorespiratory nitrogen cycle.

An estimate of the amount of GS and GDH in wheat leaves was made. The values obtained, in nKat per g fresh weight, of 40 for GS and of 54 for GDH indicate that both enzymes may be present in sufficient amounts to catalyse NH_3 reassimilation despite the high K_m of GDH for NH_3 .

Fig. 1 The photorespiratory nitrogen cycle (the complex stoichiometry of the Calvin cycle is not included).

To study the loss of NH_3 and its reassimilation *in vitro*, mitochondria were isolated from spinach leaves by the method of Douce *et al.*¹³. They were shown to produce $^{14}\text{CO}_2$ and $^{15}\text{NH}_3$ in about equal amounts from [^{15}N , 1- ^{14}C]-glycine (Table 1); serine was also produced as found previously with tobacco³ and spinach¹⁴ mitochondria. The mitochondrial preparations contained substantial amounts of GDH (about a third of the total in the original homogenate) and small amounts of GS ($\leq 0.2\%$); this GS was separated from the mitochondrial marker enzymes when the preparations were centrifuged on a sucrose density gradient. To test if the NH_3 produced by the mitochondria could be reassimilated *in situ* the various reaction components required for GDH or GS activity were added to the mitochondrial incubations (Table 1, treatments 2-4); there was no decrease in the amount of NH_3 evolved or in the ratio of $^{15}\text{NH}_3/^{14}\text{CO}_2$ released. These results, and those of Woo and Osmond¹⁴ showing that NH_3 is not retained within the mitochondria, suggest that reassimilation occurs outside.

Recent experiments have shown that GS is almost equally distributed between the chloroplast and the cytosol¹⁵; the cytosol GS, present immediately external to the mitochondria, might well function in reassimilation. To test this, chloroplasts were removed from an homogenate of pea leaves by centrifugation¹⁶. The GS was purified 100-fold from the supernatant liquid by ammonium sulphate precipitation and sequential chromatography on Sephadex G-25, DEAE-cellulose and Sepharose 4-B. Preparations, with a minimum specific activity of 111 nKat per mg protein as measured by the γ -glutamyl synthetase assay¹⁷, were added to reaction mixtures also containing mitochondria. Difficulties were experienced in combining the two systems, as the requirements of each for maximum activity differ—the conditions indicated in Table 1 represent a compromise. In the presence of GS little NH_3 was recovered from the reaction medium, indicating that it had been reassimilated, but there was increased release of $^{14}\text{CO}_2$ and the ratio of $^{15}\text{NH}_3/^{14}\text{CO}_2$ dropped to 0.13. The increase in CO_2 release could be explained by a faster rate of electron transport

Table 1 Release of NH_3 and CO_2 from [^{14}C , ^{15}N]-glycine by mitochondria

Treatment	Reaction medium	CO_2 released from glycine (μmol)	NH_3 released from glycine (μmol)	Total NH_3 released (μmol)	Ratio of $^{15}\text{NH}_3$: $^{14}\text{CO}_2$
1	Control	0.623	0.633	0.870	1.01
2	Control + 2-oxoglutarate	0.621		0.875	
3	Control + glutamate	0.615		0.945	
4	Control + 2-oxoglutarate, glutamate and oxaloacetate	0.847	0.915	1.182	1.08
5	Control	1.04	1.15	1.31	1.10
6	Control + GS	1.85	0.24	0.35	0.13

Treatments 1–4 control contained, 3.3 mM ATP, 16.4 mM (1- ^{14}C , ^{15}N)-glycine (0.05 mCi per mmol 99 atom % ^{15}N), 246 mM mannitol, 4.1 mM MgCl_2 , 8.2 mM KCl, 8.2 mM KH_2PO_4 , 0.08% bovine serum albumin, mitochondria from market spinach containing 0.8 mg protein and, where indicated, 16.4 mM glutamate, 16.4 mM 2-oxoglutarate, 16.4 mM oxaloacetate. The final volume (0.61 ml) was incubated at pH 7.2 for 20 min at 22 °C. Treatments 5–6 control contained, 4 mM ATP, 40 mM glutamate, 5 mM KH_2PO_4 , 10 mM KCl, 12 mM MgCl_2 , 10 mM MOPS, 10 mM Tris, 0.3 M mannitol, 0.2% bovine serum albumin, mitochondria from glasshouse spinach containing 0.4 mg protein and, where indicated, 2.5 nKat of glutamine synthetase. The final volume (0.60 ml) was incubated at pH 7.8 for 30 min at 22 °C. The reaction was stopped by addition of an equal volume of $\text{C}_2\text{H}_5\text{OH} \cdot \text{NH}_3$ was distilled isothermally at 20 °C into 0.1 ml 1 M H_2SO_4 in an evacuated flask after buffering the mixture at pH 10. The acid solution of $(\text{NH}_4)_2\text{SO}_4$ was mixed with 9 ml NH_3 -free H_2O , 0.1 ml 2 M NaOH and 0.2 ml 10% (w/v) sodium potassium tartrate and the tubes incubated at 25 °C for 10 min. Nessler's reagent (0.4 ml) (ref. 21) was added and after 30 min at 25 °C absorbance at 435 nm was measured. The Nessler complex was precipitated by adding four pellets NaOH (0.4 g) to each tube, mixing, and storing in the dark for 30 min. The precipitate was washed with 0.5 ml NH_3 -free H_2O and suspended in 40 μl for each μmol of NH_3 of 1 M HCl in 10% aqueous $\text{C}_2\text{H}_5\text{OH}$ (ref. 22). After standing overnight at 0–5 °C the insoluble material was removed by centrifugation and 8- μl samples of the supernatant were dried in short lengths of capillary tube at 60 °C. The residues were sealed *in vacuo* (0.2 Pa) in a pyrex tube with appropriate reagents and the ^{15}N , ^{14}N content measured by emission spectroscopy²³. Radioactive serine and CO_2 were removed and measured as described previously³.

resulting from the production of ADP from ATP by GS. This was confirmed in oxygen electrode experiments with the same batch of mitochondria.

The above results indicate that reassimilation can occur *in vitro* with GS. To confirm that this also occurs *in vivo* carefully matched flag leaves of wheat (c.v. Sicco) were detached under water, stood vertically with their bases in 3 ml of water and illuminated. Such leaves contained small amounts of NH_3 which increased when they were supplied with ^{15}N -glycine by the cut

base (Table 2). Measurement of the ^{15}N content of the NH_3 indicated that the extra amount was derived from glycine. The addition of methionine sulfoximine (MSO) together with the ^{15}N -glycine increased the amount of NH_3 derived from glycine 4.5-fold. Also, when isolated pea protoplasts were incubated with ^{15}N -glycine, MSO doubled the production of $^{15}\text{NH}_3$. There was, however, a considerable background of $^{14}\text{NH}_3$ production by the protoplasts. A similar release of NH_3 from freshly isolated poppy cells has been observed¹⁸. As MSO is a specific inhibitor of GS¹⁹, we conclude that NH_3 produced during the conversion of glycine to serine *in vivo* is normally reassimilated by GS.

On the basis of the above results we propose that photorespiration involves a cycling of nitrogen (see Fig. 1). If the generally accepted estimates of photorespiration and primary assimilation of NH_3 derived from nitrate reduction are correct, then the flux of NH_3 through the photorespiratory nitrogen cycle is an order of magnitude greater than that resulting from primary assimilation. In the scheme, the NH_3 released from glycine is refixed by cytoplasmic GS into glutamine. Glutamine and 2-oxoglutarate move into the chloroplast where, in the presence of reduced ferredoxin and glutamate synthase, two molecules of glutamate are formed; one of these molecules of glutamate becomes the acceptor molecule for another NH_3 molecule and the other provides a transamination equivalent to convert one glyoxylate to glycine while regenerating 2-oxoglutarate (a second transamination equivalent is needed and comes from serine).

As chloroplasts actively assimilate ammonia in the light²⁰, it is possible that chloroplastic GS could be partly involved, but ammonia produced in mitochondria probably first encounters the cytoplasmic GS. The conversion of glutamine to glutamate must occur solely in the chloroplast as that is the only site of glutamate synthase activity in the leaf cell¹⁵. The operation of the cycle would minimise the energy required in the cytoplasm, as the major energy-demanding step is directly coupled to the light-dependent reduction of ferredoxin. Thus, only one ATP of the three generated in the mitochondria during the conversion of two molecules of glycine to serine^{3,4,13} is needed for reassimilation of ammonia. The two molecules of ATP remaining may be used for synthetic reactions in the cytoplasm.

Table 2 Effect of methionine sulfoximine on NH_3 release from [^{15}N]-glycine

Solution supplied	Time (min)	Total NH_3 released (μmol)	NH_3 released from glycine (μmol)
Wheat leaves			
Water	45	1.7	—
	90	1.4	—
5 mM MSO	45	5.8	—
	90	12.0	—
15 mM ^{15}N -glycine	45	2.5	0.6
	90	3.5	1.4
15 mM ^{15}N -glycine + 5 mM MSO	45	8.9	2.7
	90	17.4	6.4
Pea leaf protoplasts			
^{15}N -glycine + glutamate	60	0.45	0.08
^{15}N -glycine + glutamate + MSO	60	0.68	0.16

Wheat flag leaves, each about 0.45 g fresh weight were illuminated for 40 min at 25 °C with the cut bases in water. The water was then replaced by the solutions indicated. The photon flux density at the leaf surface was 800 $\mu\text{Einstein m}^{-2} \text{s}^{-1}$ (PAR). Pea leaf protoplasts were isolated by the method of Wallsgrove *et al.*¹⁵ and an amount containing 207 μg chlorophyll incubated at 25 °C in 0.59 ml containing 16.95 mM [^{15}N]-glycine (99 atom % ^{15}N), 16.95 mM glutamate, 0.34 M sorbitol, 80 μM MgCl_2 , 42 mM Tricine pH 7.5 and, where indicated, 1.93 mM MSO. The reaction mixture was illuminated with a photon flux density of 1,200 $\mu\text{Einstein m}^{-2} \text{s}^{-1}$ (PAR) in tubes gassed with air at 300 ml min^{-1} and shaken at 1 Hz. Wheat leaves were killed in boiling H_2O and homogenised; reaction mixtures containing protoplasts were treated with an equal volume of $\text{C}_2\text{H}_5\text{OH}$. Measurements of the amount and ^{15}N content of NH_3 were as in Table 1.

Bats avoid moving objects more successfully than stationary ones

MICROCHIROPTERANS sense their environment by emitting ultrasonic signals and listening to the echoes¹. The simplest way to measure this ability is by the obstacle-avoidance test²⁻⁷, in which a bat flies between an array of stationary wires and the numbers of hits and misses are recorded. We have extended this test and made our bats fly between an array of moving as well as stationary obstacles. We were surprised to find, as reported here, that a bat can avoid moving obstacles more successfully than stationary ones.

Six *Myotis lucifugus* (the little brown bat) with an average maximum wingspan of 23 cm were tested in a room 4.6 m long, 2.2 m wide and 2.1 m high. A wooden frame containing six vertically strung nylon monofilament lines or steel wires (the obstacles) was placed in the centre of the room. The total opening of this barrier (the frame plus the obstacles) through which a bat flew was 1.8 m wide and 1.7 m high. By means of an electric motor the barrier was made to oscillate in the horizontal direction parallel to the alignment of the obstacles, with a maximum amplitude of 9 cm at a rate of 0.39 Hz, which

generated an average speed of 7 cm s⁻¹. Any effect of the movement of the frame itself on the bat's performance was eliminated by surrounding the frame with large wooden panels which were attached to the walls, ceiling and floor. Thus the bat could see the movement of the lines or wires, but not that of the frame. The sound of the moving lines or wires was negligible. All surfaces of the wooden panels, ceiling and walls were covered with convoluted polyurethane foam to reduce the echoes from them. Four different diameters of nylon lines (0.23, 0.37, 0.47 and 0.53 mm) or steel wires (0.32, 0.37, 0.53 and 1.53 mm) were used, one size at a time for each test. The distance between the obstacles was always 30 cm. A bat was made to fly between stationary obstacles at least 32 times before it was made to fly between moving ones another 32 times in order to minimise any effect of spatial memory of the position of the obstacles^{8,9}. Each bat was tested in this way as many times as possible. A hit consisted of collisions of the body or arm with the obstacles. A miss consisted of flights in which the obstacles were not touched or were lightly brushed by a wingtip with no change of flight course.

When an agile bat flew between the stationary obstacles, it negotiated them almost without hesitation. However, when the barrier was moved, the bat hovered first at one side of the flight room before flying between the obstacles. The bat was apparently more cautious when confronted with moving obstacles. Bats tended to fly between the upper central part of the barrier regardless of whether the obstacles were stationary or moving.

Contrary to our prediction, the percentage of misses by all bats was always greater for the moving obstacles than for the stationary ones, regardless of the size of the obstacles. Table 1 summarises the data for four bats which were tested with at least two different diameters of wires or lines. The average percentage of misses obtained in each of the two test conditions differed by 6.5-15%. All these differences are significant (χ^2 test, $P < 0.10$).

Myotis lucifugus flies between an array of obstacles of this sort with an average wingspan of 14 cm (60% of maximum wingspan)^{1,2}. Therefore a model bat with a wingspan of 14 cm was made from wooden sticks, steel wires and tapes. It was thrown at random, in the manner described by Hahn⁶, towards the barrier in order to find out the chance of missing the barrier. Six diameters of nylon line (0.20, 0.27, 0.33, 0.56, 0.83 and 1.0 mm) were used; Table 1 shows only the data obtained with 0.20, 0.56 and 1.0-mm lines. In general, the percentage of misses when the obstacles were moving was not significantly different from that recorded when the obstacles were stationary, regardless of the diameters of the lines. The average percentage of misses for stationary and moving obstacles of six different diameters was 65.2 and 65.4, respectively. These values are 30-40% greater than those reported earlier^{1,2,6}. Because the percentage of misses by bats obtained in either test condition was significantly greater than those found with the model bat, the bats apparently used echolocation to dodge the obstacles.

Table 1 Avoidance of obstacles by bats

Diameters of wires (w) or lines (l) (mm)	Bats tested	Stationary		Moving		Differences in average % misses	χ^2	Significance at 90% correct level $P \leq 0.10$
		Total flights	Average % misses	Total flights	Average % misses

1.0 (l)	Model	323	67	192	64	3	0.4	No

Why was a moving obstacle easier to miss (or perceive) than a stationary one? The answer is probably associated with the fact that carnivorous and insectivorous bats rely on moving prey for survival, and they apparently concentrate more intently on moving objects while hunting. In behavioural experiments, it is essential to present an animal with tasks which are more relevant to situations encountered in its natural environment.

'Motion detectors' have been found in a cat's inferior colliculus¹⁰ and auditory cortex¹¹, and it is likely that the bat's auditory system also contains neurones that are particularly sensitive to an echo source moving in a particular direction and at a particular speed. Indeed, cortical neurones sensitive to a moving sound source have been found in the big brown bat (*Eptesicus fuscus*) by P. Wasserbach (personal communication).

Pygmy chimpanzee as a possible prototype for the common ancestor of humans, chimpanzees and gorillas

A CONVINCING theory of human origins must clarify man's relationships with living primates and with the ancestral forms known only through fossils. Phylogenetic relationships have previously been determined mainly by anatomical similarities, but now, biochemical similarities provide independent criteria for evolutionary relationships. Albumin and transferrin immunology, immunodiffusion, DNA annealing and amino acid analysis all indicate that chimpanzees, gorillas and humans share a substantial common ancestry, and that the Asiatic apes (gibbons and orangutans) diverged earlier from this lineage¹⁻³. These findings directly conflict with the more widely held view that all the great apes diverged from a common ancestor long after the 'origin' of the evolutionary line leading to modern humans⁴. The molecular data consistently suggest a much more recent origin of the man-chimpanzee-gorilla separation than was previously imagined, namely, in the range of 4-6 M yr ago^{3,5}. These data show that, although the two chimpanzee species (*Pan paniscus* and *P. troglodytes*) are biochemically distinct, they are more closely related to each other than either is to humans or gorillas^{6,7}. The chimpanzees speciated, then, after the initial three-way split. We therefore, here contend that, among living species, the pygmy chimpanzee (*P. paniscus*) offers us the best prototype of the prehominid ancestor. Biochemical, morphological, behavioural and palaeontological data support this proposition and argue for a relatively recent and accelerated divergence of the hominid from the pongid line.

If this cladogram is correct, then an ancestor for the earliest hominids must also be a suitable ancestor for chimpanzees and

gorillas. The morphological similarities between the three groups should logically be derived from the common ancestor, rather than by evolutionary convergence, or by parallelism from distinct primate lineages. In fact, the modern African apes may be viewed as size variants in a single morphotypic series, going stepwise from the smaller *P. paniscus* to the large male gorilla. The scant hominid fossil record during the past 4-8 M yr, and the absence of any fossil chimpanzees or gorillas, forces us to work backwards from the living hominoids to reconstruct a prototype of the common ancestor.

Chimpanzees have generally been considered closer to this prototypic ape than gorillas, because the latter are more specialised morphologically and behaviourally. They are larger and males are twice the size of females; they have a more specialised diet, more restricted habitat and less flexible social behaviour than chimpanzees. Morphologically, pygmy chimpanzees are more 'generalised' in body size, body build and sexual dimorphism than the common species and may provide a better prototype for studying the derivation of the earliest hominids and African apes.

Pygmy chimpanzees on the average weigh less than the average common chimpanzee, but with much overlap: 25-48 kg, compared to 25-60 kg or somewhat more⁸. Pygmy chimpanzees have smaller facial and canine dimensions, smaller average cranial capacities (350 cm³ compared with 390 cm³), and the two species can be discriminated on mandibular length alone⁹.

Fig. 1 Molecular cladogram showing genetic relationships of the ape and human lineages.

Pygmy chimpanzees have a narrower trunk and more gracile upper body, as reflected in significantly smaller clavicular length, scapular dimensions and iliac and sacral breadths⁸. Their upper and lower limbs are of about equal length, whereas arms of common chimpanzees are relatively longer.

As to sexual dimorphism, pygmy chimpanzees are moderately sexually dimorphic in body weight, but no dimorphism can be detected in cranial capacity, limb bone lengths or robusticity, or in anterior and posterior dentition¹⁰. They have relatively small and only slightly dimorphic canine teeth¹¹. Overall, this is less dimorphism than occurs in common chimpanzees and no more than occurs in modern humans.

Observations on the behaviour of pygmy chimpanzees, either in their natural habitat in the Zaire River Basin or in captivity, have not been extensive. They feed high in trees, move and feed on the ground^{12,13}, and in captivity walk bipedally more than do common chimpanzees (S. Savage-Rumbaugh, personal communication). They therefore encompass the spectrum of locomotor behaviour of living African hominoids: arboreality, terrestriality and bipedality. Laboratory and field studies reveal pygmy chimpanzees as highly intelligent and flexible in feeding, locomotor, sexual and communicatory behaviour¹⁴⁻¹⁶.

Given these morphological and behavioural data, we maintain that pygmy chimpanzees present a general pattern from

Table 1 Comparison of pygmy chimpanzee and early hominid pelvis, femur and humerus (in mm)

Measurement	Early hominids	Pygmy chimpanzees
Femur length	280*, 280†	293 (264–315)
Femoral head diameter	31†	30.5 (28–34)
Acetabular diameter	37†	36 (32–38)
Innominate length	170†	253 (232–272)
Iliac breadth	113†	97 (80–118)
Sacral breadth	76†	63 (51–70)
Humerus length	235*	285 (250–307)

* AL 288–1 from Hadar, Ethiopia¹⁸.

† Sts 14 from Sterkfontein, South Africa. Measurements from A.L.Z. (unpublished data); femur length from Lovejoy²³.

which other African hominoids could have developed. This contention is further supported by comparing pygmy chimpanzees with the earliest hominids.

The fossil record, based on dentition, shows the occurrence of *Australopithecus* by 3.5 M yr ago in the mosaic savannas of Eastern Africa¹⁷. By 3 M yr ago, the hominids were distinct from apes in the broader and shorter pelvis, larger cranial capacity, larger postcanine teeth and somewhat smaller canines^{18,19}.

P. paniscus provides a suitable comparison for *Australopithecus*²⁰; they are similar in body size, postcranial dimensions and, as Figs 2 and 3 show, even in cranial and facial features, although this *Australopithecus* has a larger cranial capacity (485 cm³)²¹ than *P. paniscus* (350 cm³).

Postcranial dimensions are given in Table 1. Femoral length, femoral head and acetabular diameters are very similar. Humerus and innominate lengths, and breadths of sacrum and ilium are different. These findings demonstrate early hominid affinities with apes. Probably the initial acquisition of hominid upright locomotion entailed reduction of upper limb length and broadening of the ilium and sacrum.

Homo and *Pan* (both species) differ in their genomes by approximately 1%, a value characteristic of sibling species²². The genetic changes accounting for the morphological differences between man and chimpanzee may be only a small fraction of that amount. A few regulatory genes may have large somatic effects, whereas the remaining structural genes may be time dependent in their rate of fixation, and of little selective significance.

Fig. 2 Side view, drawn to scale, of Sterkfontein 5 (above) and adult female *P. paniscus* (below).

Fig. 3 Front view, drawn to scale, of Sterkfontein 5 and adult female *P. paniscus*.

The ultimate strength of any hypothesis rests on its compatibility with all lines of evidence, on its ability to withstand falsification and on its power of prediction. We hypothesise (1) that as our knowledge of the fossil record improves, hominids before 3.0 M-yr ago should continue to converge on the pygmy chimpanzee-like condition, cranially and postcranially, as they seem to do dentally, (2) that Pliocene pongids ancestral to chimpanzees and gorillas should do likewise, and (3) that at least one lineage of late Miocene ape (perhaps *Ramapithecus*) should continue to develop evolutionary trends begun in the early Miocene and evolve into a form similar to the extant pygmy chimpanzee.

Axons from eyes grafted in *Xenopus* can grow into the spinal cord and reach the optic tectum

THE transplantation of embryonic eyes in Amphibia is a long established approach for testing the ability of nerve fibres to grow through unusual regions of the central nervous system^{1,2}. As the behaviour of growing ectopic fibres may disclose the mechanisms of axonal guidance³⁻⁷, this approach has recently

Fig. 1 Tadpole of *Xenopus laevis* with a third eye grafted at embryonic stage 23 (ref. 13) and now (stage 58) growing above the spinal cord. The brain and the normal eyes with their optic nerves can be seen through the transparent tissue of the tadpole head. Embryos were obtained in our laboratory by induced mating¹⁴ of wild animals and were operated on in full-strength Niu and Twitty solution¹⁵ containing antibiotics (10,000 U l⁻¹ of penicillin G and 25 mg l⁻¹ of streptomycin sulphate) and anaesthetic (0.02% MS-222, Sandoz). In the sagittal silhouette of the tadpole CNS the paths of optic fibres issuing from the normal (1) and grafted eyes (2-4) are represented. (1) Normal optic tract terminating in the anterior optic tectum; (2) ectopic fibres terminating in the medulla oblongata in triocular and in blinded (that is, binocularly enucleated) animals; (3) ectopic fibres terminating in the posterior optic tectum in blinded animals; (4) ectopic fibres growing caudally. Scale bar (applies to photograph only), 1 cm.

attracted new interest⁸⁻¹². We are studying the behaviour of optic fibres entering the spinal cord from a heterotopic eye grafted on to the dorsal trunk region of *Xenopus* embryos^{10,11}. Here we report on the paths used by ectopic fibres to travel in the spinal cord, their possible termination in the hindbrain, and their ability to reach the optic tectum.

Eye vesicles from *Xenopus laevis* embryos at stage 25 (ref. 13) were grafted on to the dorsal region of other embryos at stage 23. Results were studied at larval stages. In 52 tadpoles, the grafts developed into morphologically normal eyes located on the back of the animal, just dorsal to the spinal cord and at different distances from the brain (Fig. 1). Twenty animals (out of the 52 mentioned above) were cut sagittally and stained by Holmes' silver method¹⁶ for histological analysis: seven of the grafted eyes had developed an optic nerve whose fibres entered the spinal cord. These fibres seemed to grow mainly rostrally. We have confirmed this by tracing the paths of degenerating fibres in the remaining 32 tadpoles. Twelve of these animals had a considerable number of degenerating fibres in the spinal cord (Fig. 2). In each case we found most argyrophilic debris rostral to the graft; a smaller amount occurred caudally. Quantification of fibres in this type of preparation is not possible, but we estimate that approximately three-quarters of the fibres grew rostrally. No specific path seems to have been used by these optic axons; degenerating fibres were broadly distributed in the dorsal half of the white matter of the spinal cord (Fig. 2a). In particular, they

Fig. 2 Degenerating fibres in the spinal cord of experimental tadpoles. Horizontal section; rostral is left. The grafted eye was opened and the retina was gently peeled out. After 24 h the animals were fixed in neutralised 10% formalin and processed to demonstrate degenerating nerve fibres and terminals by a modification of Nauta's reduced silver method¹⁷. a, The ectopic fibres are localised near the central grey (CG); they were found bilaterally in various positions inside the dorsal white matter, but never close to the pial surface (between arrows). b, Degenerating fibres in the dorsal funiculi; in this region (hindbrain), they are diverging. Scale bar, 100 μ m.

were not grouped near the dorso-lateral surface of the spinal cord, as described by others^{9,12}. In two cases a large proportion of degenerating fibres was concentrated in the dorsal funiculus (Fig. 2*b*). In all cases they occurred bilaterally.

The possible termination of ectopic fibres was studied in the same set of 32 animals mentioned above. In an initial series of 17

12 h after eye transplantation and 15 h before outgrowth of optic fibres¹³. We processed the tadpoles (stages 52–57) to trace the ectopic fibres. In this second series (the remaining 15 tadpoles of the 32 mentioned above), we found three cases with extensive terminal degeneration in the optic tectum, as well as two cases with a weaker tectal projection from the ectopic eye. Terminal degeneration was bilateral and diffuse in the superficial layer of the posterior part of the optic tectum (Fig. 4*a*) and, ventrally, near the nucleus isthmi. In these five cases, bilateral terminal degeneration was also found in the solitary tract.

Sharma⁸ and Constantine-Paton and Capranica⁹ have grafted eyes in *Rana* on to the dorsal diencephalon and the internal ear region, respectively. Their results led to the suggestion⁹ that optic fibres are inherently specified for a dorso-caudal growth, relative to the overall polarity of the brain. The extensive growth of ectopic fibres in a rostral direction along the spinal cord, previously reported by us¹¹ and by Katz and Lasek¹², does not agree with this suggestion. The varied location of degenerating fibres along the spinal cord described here does not support the idea that axons from grafted eyes are growing 'in a specific set of

Fig. 3 *a*, Same experimental situation as Fig. 2. Horizontal section; rostral is left. Terminal degeneration is inside the right solitary tract (the phenomenon was bilateral). The nucleus of the solitary tract is not clearly delimited in Amphibia; neurones surrounding the solitary tract send their dendrites into it to receive the terminals from the tract¹⁸. Lateral to the solitary tract (top right) are some degenerating fibres. *b*, Left solitary tract of a control animal in which the dorsal spinal cord was sectioned 24 h before death. No terminal degeneration is present. Scale bar, 100 μ m.

tadpoles with a third eye grown on their back, we found four animals (stages 52–57) with evidence of terminal degeneration in the hindbrain (in three tadpoles there was no terminal degeneration in spite of the presence of optic fibres in the spinal cord). The terminal degeneration was restricted to the 'nucleus' of the solitary tract (Fig. 3*a*)—always occurring bilaterally and along its entire extent—with the exception of one case showing weak terminal degeneration lateral to the nucleus isthmi. To establish whether the above results were due to damage of the spinal cord during enucleation, control experiments were carried out in four normal tadpoles by transecting the dorsal half of the spinal cord and adopting a 24-h survival time, as for grafted eyes. No terminal degeneration was found in the solitary tract (Fig. 3*b*).

To understand why ectopic fibres did not reach the optic tectum (the main natural target of optic fibres¹⁹), we removed both normal eyes of the host embryos at stage 26, that is, about

Fig. 4 *a*, Same experimental situation as Fig. 2, except that both normal optic vesicles of the host embryo were removed 12 h after eye transplantation. Horizontal section; rostral is left. Terminal degeneration is in the posterior part of the right optic tectum (the phenomenon was bilateral). During larval stages the posterior optic tectum is not yet laminated. On the extreme right is the postero-lateral corner of the tectum and its border (arrow) with the cerebellum. In grafted and blinded tadpoles the terminal degeneration in the tectum was always accompanied by terminal degeneration in the solitary tract (see Fig. 3*a*) and by degenerating fibres in the spinal cord (see Fig. 2). *b*, Corresponding region of the left optic tectum of a triocular tadpole whose grafted eye successfully innervated the spinal cord. No terminal degeneration is present. The specimen shown here is the same one whose solitary tract is represented in Fig. 3*a*. Scale bar, 100 μ m.

pathways¹². The adoption of a certain route of growth and the choice of the direction of growth do not necessarily depend on the same mechanism. Are directional cues encoded in the overall polarity of the brain or in the location of the target relative to the graft? For optic fibres growing rostrally in the spinal cord, the latter would seem to be the case. The mechanism by which a target organ could guide axonal growth remains to be explained.

The plasticity of growing optic fibres is proved not only by their ability to follow unusual pathways in the CNS, but also by their anomalous termination. We found that rostrally growing ectopic fibres terminate in the nucleus of the solitary tract. Future ultrastructural and electrophysiological investigation will show whether functional synapses are formed within this nucleus, which normally receives visceral signals. Ectopic fibres were found to terminate in the caudal part of the optic tectum only in blinded animals. It is difficult to explain the lack of such projection in triocular animals in terms of competition for terminal space; at very young larval stages (when ectopic fibres could have reached the tectum) normal optic fibres terminate in the rostral part of the tectum, which becomes fully colonised only after stage 57 (refs 20, 21).

It will be necessary to analyse in detail the embryological nervous system as it interacts with growing ectopic axons, before attempting to understand the mechanisms underlying such interaction. In our view the adoption by the ectopic axons of a certain route may depend on the options offered by the experiment (for example, level of penetration into the CNS), and on a hierarchy of preferred interactions with the surrounding tissues (through cell surface recognition²²). The present work focuses attention on the role of a target, in this case the optic tectum; both its position (relative to the graft) and its input (from normal eyes) seem to affect the behaviour of optic fibres issuing from the grafted eye.

We thank P. G. H. Clarke, D. O. Frost and L. J. Garey for discussions, A. Trollet for assistance and M. Gaillard for help with the illustrations. This work was supported by grant 3.776 from the Swiss NSF (to H.V.d.L.).

Microscopic epididymides in testicular feminisation

MICE bearing the X-linked testicular feminisation (*Tfm*)¹ gene in the hemizygous (X/Y) state have been presumed to have no traces of the male genital system. Unlike normal genetic males², they are apparently unresponsive to the androgens produced by the developing testes^{3,4}, and it has been presumed that derivatives of the embryonic mesonephric (Wolffian) duct system (MDS) are unable to survive in *Tfm*/Y males. I describe here, however, microscopic components of the complex comprising rete testis, efferent ductules, epididymis and, sometimes, vas deferens in adult *Tfm*/Y mice. These structures are unrelated to the effects of the presumed mutation *O^h*, to which the microscopic epididymides of some *Tfm*/Y mice have been ascribed⁵.

Because it has not been known whether *Tfm*/Y mice without *O^h* possess microscopic epididymides, I examined such adults (6–33 weeks). As the *O^h* X chromosome carries the blotchy (*Blo*) mutation, mice with *Blo* (*n* = 3) and without (*n* = 2) were studied. They were bred from stock obtained from U. Drews, Münster, and J. Tønnes Nielsen, Aarhus, respectively. Both strains originate from Harwell.

Right and left gonads, with paragonadal material from the caudal pole of the kidney to the internal inguinal ring, were fixed and embedded *en bloc* in paraplast. Serial 7–12 µm sections of the entire block (~1,500 sections per block) were stained with haematoxylin and eosin, and examined by light microscopy.

All the mice possessed rete testis, efferent ductules and microscopic epididymides on both sides (Fig. 1), and in each case there was continuity between epididymis and rete. The epididymides resembled those reported in *Tfm O^h Blo*/Y mice⁵. A vas deferens could sometimes be identified. The epithelium lining these mesonephric derivatives was mainly of the low cuboidal type attributed to *Tfm* cells^{5–8} in *Tfm*/+ heterozygotes masculinised by the sex-reversal gene *Sxr*⁹. However, isolated areas of taller, stereociliated or ciliated epithelium were seen (Fig. 2). No simple correlation between age and the degree of development of MDS was evident.

Microscopic epididymides are thus evidently a trait of *Tfm*, not of the *O^h* state. My observations also have a bearing on previous conclusions drawn from data on masculinised *Tfm*/+ heterozygotes. The assumption that the cuboidal epithelial cells in these heterozygotes represent surviving *Tfm* cells receives some support. There is, however, no need to suggest intercellular diffusion or metabolic co-operation^{5–8}; these cells are clearly capable of independent survival. Furthermore, stereocilia or cilia can no longer be used to distinguish *Tfm* from wild type cells⁸ in such heterozygotes. Indeed, there is no reliable criterion for this purpose.

The survival of epididymal and related structures in adult *Tfm*/Y mice suggests that the cells involved are either not dependent on testosterone or they are not entirely insensitive to it. Because the enzyme β-glucuronidase is histochemically

Fig. 1 Cross-section of the epididymis of a 9-week-old *Tfm*/Y mouse without *Blo* (×60).

Fig. 2 Tubule cross-section of epididymis of a 9-week-old *Tfm/Y* mouse without *Blo* ($\times 750$), showing ciliated and/or stereociliated epithelium. (Both cilia and stereocilia appear to be present in normal mouse epididymides¹³.)

inducible by androgen in normal epididymis¹⁰, as in the kidney¹¹, studies of that enzyme in the microscopical epididymides may resolve this problem.

Not only the MDS but also the testis itself is abnormally small in *Tfm/Y* hemizygotes. It is possible that initial embryonic determination, establishment and maintenance of both testis and MDS are independent of testosterone but that normal maturation of both is under its control. Thus in one possible interpretation of my data, *Tfm* cells in these organs may be insensitive to androgens, but survive because only some aspects of normal function and development are dependent on such hormones. Alternatively, ontogenetic changes in affinity of repressor molecules for inducer (androgen), or for receptor sites, or developmental loss of the latter, could account for my observations.

Rete components of the MDS are essential for initiation of meiosis in the mouse testis¹², and in *Tfm/Y* mice meiosis is indeed initiated and proceeds to metaphase¹. On this basis the presence of a functional rete in *Tfm* mice could have been predicted. Conversely, it can be deduced from my observations that at least part of an MDS composed entirely of *Tfm* cells is functionally competent, independent of any metabolic co-operation with wild type cells. This system may be of value in studies of developmental aspects of hormonal competence.

Uniparental inheritance is promoted by delayed division of the zygote in *Chlamydomonas*

SEXUAL REPRODUCTION in *Chlamydomonas reinhardtii*, a heterothallic, unicellular green alga, yields two types of zygotes: the thick-walled, dormant zygospore (meiotic), and less frequently, the vegetative zygote which divides mitotically soon after initial gamete fusion to produce stable diploid progeny^{1,2}. Although vegetative zygotes account for less than 5% of the products of gamete fusion, their diploid progeny can be easily

Fig. 1 Comparison of chloroplast gene transmission patterns in zygospores and vegetative zygotes of *C. reinhardtii*. Chloroplast gene transmission in zygospores: *a*, the chloroplast streptomycin-resistance mutation, *Sr* (shaded circles) is transmitted to all four meiotic products by greater than 90% of the zygospores if introduced through the mt⁺ parent, and is transmitted to none of the progeny if introduced through the mt⁻ parent. *b*, Biparental inheritance, observed for less than 10% of the zygospores, results in the transmission of both the *Sr* and wild-type *ss* (open circles) chloroplast alleles to the meiotic products. *c*, Paternal zygospores, transmitting only the chloroplast alleles of the mt⁺ parent, represent less than 1% of the zygospores in most crosses. Regardless of the pattern of chloroplast gene transmission, the nuclear mating-type alleles (indicated by + and -) segregate 2:2 among the meiotic products. Chloroplast gene transmission in vegetative zygotes: *d*, Biparental vegetative zygotes, transmitting the chloroplast alleles of both parents to their diploid progeny account for greater than 70% of the vegetative zygote population in most crosses. Segregation of parental chloroplast alleles occurs gradually and is completed within 20 generations. *e-f*, less than 25% of the vegetative zygotes exhibit uniparental chloroplast gene transmission, with uniparental maternal inheritance (*e*) usually being much more common than uniparental paternal (*f*). (The mendelian auxotrophic markers required for the selection and identification of vegetative zygotes² are not indicated in the figure.)

Opposite mating types in all of the above crosses also carried recessive complementary mendelian mutations conferring a requirement for exogenous arginine. Thus, vegetative zygotes were selected by plating mated cells on medium lacking arginine (acetate was provided as an organic carbon source for all isolations). Zygospores were matured in darkness for 7–10 d on the same medium; germination was subsequently induced by transfer to medium containing arginine and incubation in the light. 50–64 vegetative zygotes and/or 100–200 zygospores were analysed for transmission of the chloroplast antibiotic resistance markers. Chloroplast inheritance patterns are abbreviated as follows: *BP*, biparental; *UPm*, uniparental maternal; *UPp*, uniparental paternal.

selected on minimal medium by crossing haploid strains which carry complementing auxotrophic mendelian mutations². I report here that differences in chloroplast inheritance observed between meiotic and mitotic zygotes of *Chlamydomonas* are correlated to the timing, rather than the nature, of their first divisions. Environmental conditions which delay the first post-mating division of vegetative zygotes result in uniparental inheritance while favourable post-mating environments promote biparental inheritance of chloroplast genes.

Chloroplast inheritance in *C. reinhardtii* is generally described as uniparental since 90% or more of the zygospores transmit to their progeny only those chloroplast alleles derived from the 'maternal' (mating-type plus, *mt*⁺) parent^{3–5}. Exceptional zygospores may transmit the chloroplast alleles of both parents (biparental zygospores), or rarely, may transmit only those alleles initially carried by the 'paternal' (mating-type minus, *mt*[−]) parent (Table 1*a*, Fig. 1). Nearly all investigations on chloroplast inheritance in *Chlamydomonas* have centred on the meiotic zygospore. The notable exceptions are studies by Gillham^{6,7} reporting a tendency toward biparental chloroplast gene transmission in vegetative zygotes (see Fig. 1) and suggesting a correlation between their inability to undergo meiosis and their failure to exclude paternal chloroplast alleles.

In work to be reported elsewhere, I found that the culture medium used to isolate vegetative zygotes affected the pattern of chloroplast gene transmission. Media promoting the most rapid vegetative growth also promoted biparental inheritance. This suggested that the observed differences in inheritance patterns between zygospores and vegetative zygotes (see Table 1*a*, Fig. 1) might result from differences in the timing, rather than in the nature (meiotic or mitotic), of their first post-mating divisions. To test this hypothesis I attempted to induce a temporary dormancy in the vegetative zygotes. Experimental procedures which can be used to promote maturation and extend dormancy in zygospores include nitrogen starvation⁸ and incubation in darkness⁹; it seemed likely that either of these treatments might also delay the first division of vegetative zygotes.

When the vegetative zygotes were selected in darkness, the recovery of macroscopically visible zygote clones was delayed as

compared to control isolations under continuous illumination. Furthermore, chloroplast gene transmission shifted toward uniparental maternal inheritance (Table 1*b*). By returning the vegetative zygotes to the light after various periods in darkness, a stepwise change in the inheritance pattern can be observed (Fig. 2*a*). However, as vegetative zygotes (but not zygospores) do eventually divide in darkness (if an organic carbon source is provided), this method does not make it possible to delay the first division indefinitely.

In contrast, the nitrogen-free medium used to induce gametogenesis and mating in *C. reinhardtii*¹⁰ also blocks post-mating cell division. By continuing to starve cells for nitrogen after mating, division of the vegetative zygotes can be delayed for at least 6 d with no subsequent loss in viability. Increasing the duration of the post-mating nitrogen starvation period led to a decrease in the frequency of biparental chloroplast gene transmission until uniparental maternal inheritance, normally associated with zygospores, became the predominant inheritance pattern in the vegetative zygote population also (Fig. 2*b*).

To verify that the experimental conditions of dark incubation or nitrogen starvation delayed the first division of the vegetative zygotes, and to estimate the approximate extent of this delay, subsamples of the mating population were plated on standard agar-solidified medium and incubated in various conditions. Periodically, sterile liquid was added to the surface of the sample plates and the adherent cells were respread. Respreading after zygote division had occurred would be expected to result in an increase in the number of colonies subsequently recovered.

In this manner, it was shown that: (1) incubation in darkness delayed the onset of the first division by approximately 40 h (Fig. 3*a*); (2) no division of the vegetative zygotes occurred during maintenance in nitrogen-free medium (Fig. 3*b*), and (3) under continuous illumination, division always occurred within 30 h after the return of available nitrogen, regardless of the duration of the previous dormant (nitrogen-starvation) period.

While these observations demonstrate a previously unrecognised potential for uniparental inheritance in vegetative zygotes, they perhaps more importantly reveal a remarkable influence of external environment on chloroplast inheritance. This influence,

which extends also to zygospores of *C. reinhardtii*^{8,11,12}, must be borne in mind when defining laboratory conditions for studies on chloroplast inheritance, and when interpreting and comparing the results of such experiments conducted in different laboratories.

The correlation between delayed division and uniparental inheritance suggests an alternative to previous arguments that uniparental inheritance is, in itself, of direct selective advantage^{13,14}. The molecular mechanism responsible for uniparental inheritance in *Chlamydomonas* apparently involves extensive degradation of zygotic chloroplast DNA (normally present as multiple copies of a small genome in vegetative cells)¹⁵⁻¹⁸. Perhaps chloroplast genome polyploidy is a luxury permitted only in an optimum environment, and reduction in ploidy level represents an energy-conserving measure essential to the maintenance of viability in a hostile environment. Viewed in this way, uniparental inheritance is seen as an indirect consequence of direct selection, in evolutionary history, for the dormant, highly resistant stage (the zygospore) in the life cycle of *Chlamydomonas*.

Fig. 2 Effect of post-mating environmental conditions on the transmission of chloroplast genes in vegetative zygotes of *C. reinhardtii*. *a*, Effect of post-mating incubation in darkness. Chloroplast mutants resistant to neomycin (*mt*⁺ parent) and to streptomycin (*mt*⁻ parent) were crossed following standard procedures^{8,9} and the mated cells plated on acetate-supplemented minimal medium for the selection of vegetative zygotes (complementary recessive nuclear mutations to arginine auxotrophy were carried by opposite mating-types). Subsamples of the selection plates were incubated in darkness for the periods indicated and were then transferred to continuous light. Resultant zygote colonies were replica-plated to medium supplemented with 75 $\mu\text{g ml}^{-1}$ neomycin and to medium supplemented with 100 $\mu\text{g ml}^{-1}$ streptomycin. Biparental vegetative zygote clones are defined as those which yield growth on both of the antibiotic test media. *b*, Effect of post-mating nitrogen starvation. Parental strains are as described in (*a*) above. Gametogenesis and mating were carried out in nitrogen-free medium and the mated culture held in the same medium for 6 d. Samples were periodically withdrawn at the times indicated and plated on nitrogen-containing, acetate-supplemented standard medium under continuous illumination. Biparental zygote clones were defined as described above. Open and shaded circles represent separate repetitions of the same cross. 64 vegetative zygote clones were analysed from each dark incubation (*a*) or nitrogen-starvation (*b*) period. Vertical bars indicate 95% confidence limits.

Fig. 3 Effect of post-mating environmental conditions on the timing of the first division of vegetative zygotes of *C. reinhardtii*. *a*, Effect of post-mating incubation in darkness. Mated cells were plated on acetate-supplemented minimal medium and incubated either under continuous illumination (○) or in darkness (●, ■). At the times indicated, the adherent cells were respread. Sample plates incubated in darkness were returned to the light at each indicated time both with (●) and without (■) respreading. The time of the first vegetative zygote division can be estimated by comparing the number of colonies recovered on respread and non-respread plates. *b*, Effect of post-mating nitrogen starvation. Mated cells were removed from nitrogen-free medium and were plated on acetate-supplemented minimal medium within 2 h after mating (●), and after 24 (○), 48 (■), or 72 (□) h of post-mating nitrogen starvation. Adherent cells were respread periodically after plating (the first symbol, in each case, indicates the average colony count on non-respread plates).

I thank Drs N. W. Gillham, J. E. Boynton, C. W. Birky, Jr and R. Bruce Nicklas for discussions and R. A. Lewin for critical review of the manuscript.

Sensitivity of corticosteroid-dependent insulin-resistant lipogenesis in marrow preadipocytes of obese-diabetic (db/db) mice

It is well known that adipocytes with specific cell-membrane insulin receptors respond to insulin by increasing glucose uptake, oxidation and lipogenesis in the presence of glucose¹⁻⁴. Maintenance of adipocyte insulin sensitivity during a state of relative muscle cell insulin resistance has been considered a possible mechanism for obesity in diabetes mellitus⁵. I now report that a distinct cell phenotype resists insulin but accumulates lipid in response to corticosteroid. Furthermore, corticosteroid-induced lipogenesis is significantly greater in marrow preadipocytes of mutant diabetic-obese mice.

Weanling 6-8 week-old NIH/Swiss, BALB/c (National Cancer Institute), C57 BL/KsJ-db (genotype *db+/db+*) diabetic mice and their control littermates *db+/m+* and *m+/m+* (Jackson Laboratories) were killed by cervical dislocation and the marrow contents of a single femur and tibia were flushed in 10.0-ml volumes of Fisher's medium (Gibco), supplemented with 25% serum (donor horse, fetal calf or goat), into plastic flasks (Corning) as before⁶ and standardised to 2.0×10^7 cells per culture. A sample of donor horse serum (Flow Laboratories, Manchester) which has been reported to induce lipid accumulation in marrow cells⁶, was provided by Dr T. M. Dexter. The serum factor(s) stimulating lipid accumulation by these cells and their role in maintaining haemopoiesis *in vitro* are unknown.

Fig. 1 Morphological appearance of the adherent cell population in a 4-week marrow culture grown in: *a*, 'deficient' lot 4107064 horse serum ($\times 100$); or *b*, the same serum supplemented with 10^{-7} M hydrocortisone sodium hemisuccinate ($\times 200$).

Fig. 2 Kinetics and sensitivity of corticosteroid-induced adipocyte colony formation in obese-diabetic compared with control mouse marrow. *a*, Results are the mean of at least three cultures at each time grown in 10^{-7} M insulin (open symbols) or 10^{-7} M hydrocortisone sodium hemisuccinate (closed symbols) for each mouse strain; *b*, results are the mean of total adipocyte colonies per flask scored at week 6 for at least three cultures at each concentration of hydrocortisone sodium hemisuccinate alone (open symbols) or in the presence of 10^{-7} M insulin in addition to steroid (closed symbols). $\square$, C57BL/Ks-J (db/db); $\circ$, C57BL/Ks-J (db/m or m/m); $\diamond$, NIH/Swiss; and $\triangle$, Balb/c.

Cultures were incubated at 33, 31 or 37 °C and were depopulated and fed by weekly removal of half the flask volume (5.0 ml) and replacement by an equal volume of fresh medium. Cultures were recharged at week 4 by addition of the contents of a second mouse femur⁶. Sera from several sources were supplemented with each of several concentrations of hormones listed in Table 1, and cultures were scored daily for the number of macroscopic adipose cell-containing colonies per flask and of adipose cells per high-powered microscopic field (Olympus inverted microscope). As Table 1 shows, Manchester serum supported formation of more than 100 macroscopic adipose cell colonies per flask by week 4. This was associated with more than 100 adipocytes per high-powered field in the centre of such a colony. Each of 16 lots of horse serum (Flow Laboratories, Rockville), eight lots of fetal calf serum (Colorado Serum Co. or Gibco), or goat serum in concentrations ranging from 10 to 50% failed to stimulate adipose cell differentiation (Table 1). Addition of arachidonic acid (Nu-chek, Elysian, 0.5–500 $\mu\text{g ml}^{-1}$), bovine insulin (Sigma, 0.5–500 $\mu\text{g ml}^{-1}$), butyric acid, dimethylsulphoxide or idoxuridine to deficient sera failed to stimulate adipocyte differentiation.

In contrast, addition of hydrocortisone sodium hemisuccinate (Solu-Cortef, Upjohn) in doses between 0.05 and 500 ng ml^{-1} (10^{-10} – 10^{-6} M) resulted in dose-dependent adipose cell differentiation (Fig. 1) with 12 of the 16 lots of donor horse serum and to a lesser extent with fetal calf or goat serum (Table 1 and Fig. 2). Addition of corticosteroid to Manchester serum did not further increase the numbers or size of adipocyte colonies. Removal of corticosteroid from the medium after adipocytes had differentiated was associated with gradual loss of adipocytes. Thus, the continued presence of corticosteroid was absolutely required.

Other corticosteroids were effective as well as the mineralocorticoid, *d*-aldosterone and the 17-hydroxy adrenal corticosteroid corticosterone (Table 1). Oestrogenic, androgenic or progestational steroids were inactive in the range 10^{-10} – 10^{-4} M (Table 1). With optimal corticosteroid concentration, 10^{-7} M, adipocyte differentiation increased directly with serum concentration in the range 0.5–25.0%, thus arguing against the presence of a serum inhibitor. Corticosteroid-induced adipocyte differentiation was observed in cultures at 31 and 37 °C but was optimal at 33 °C.

Marrow from C57BL/Ks-J (db/db), (db/m), (m/m), BALB/c and NIH/Swiss mice was next compared for steroid sensitivity of adipocyte differentiation. There was no detectable lipid accu-

mulation in *db+db+* or control littermate marrow preadipocytes in response to increased fatty acid concentration or insulin (Fig. 2a). When 2×10^7 marrow cells were cultured in 10^{-7} M hydrocortisone, *db/db* preadipocytes yielded significantly more adipocyte colonies after 8 weeks than did preadipocytes from control littermates. Figure 2b shows that this reflected a true increase in sensitivity of *db/db* cells to corticosteroid. Significant adipocyte differentiation was detected at a corticosteroid concentration (10^{-9} M) 100 times lower than that required by marrow from control littermates.

Evidence that marrow preadipocyte differentiation was truly insulin independent was provided as follows. Cultures were preincubated in insulin (10^{-10} – 10^{-7} M) for up to 4 weeks with no alteration in the number of adipocyte colonies induced after the addition of 10^{-7} M corticosteroid at week 4. Addition of insulin to corticosteroid-containing cultures of *db/db* or control marrow did not further stimulate or block lipogenesis (Fig. 2b).

When adipocytes differentiated in hydrocortisone-treated cultures 5–7 times as many adherent cells and 100–500 times as many nonadherent cells were detected in culture flasks at weeks 4, 8, 12 and 14 as in untreated cultures. There was persistent proliferation of pluripotent haemopoietic stem cells (CFUs) and GM-progenitor cells (CFUc) for at least 14 weeks in steroid-treated cultures while untreated cultures failed to support haemopoiesis after week 6 (Fig. 3). It is not known whether the increased numbers of CFUc and CFUs arose from corticosteroid-induced cells or were present in the inoculum and required corticosteroid for their proliferation or maintenance of a growth stimulatory microenvironment. Recent data indicate that when preadipocyte differentiation is blocked by Kirsten murine sarcoma virus, *in vitro* haemopoiesis¹⁶ is inhibited.

Epitidymal adipocytes resist lipogenesis by insulin after insulin-preincubation and this has been shown to represent

Fig. 3 Influence of corticosteroid-induced marrow preadipocyte differentiation on pluripotent haemopoietic stem cell and GM-progenitor cell proliferation *in vitro*. Cultures of NIH/Swiss mouse marrow were collected weekly by removal of half the flask volume (5.0 ml) and assayed for total numbers of spleen colonies (CFUs) and *in vitro* GM colonies (CFUc)⁶⁵ detected per 10^5 cells. Results are corrected for the total number of colony-forming cells in the 5.0-ml removed and are the mean and standard error for at least three flasks at each week. a, CFUc for 25% 'deficient' lot 4107064 horse serum alone, ●; or with 10^{-7} M hydrocortisone sodium hemisuccinate, ○. b, CFUs for 25% 'deficient' horse serum alone, ●; or with 10^{-7} M hydrocortisone sodium hemisuccinate, ○.

Each week drugs (Sigma) were dissolved in ethanol or acetone according to published procedures in 1,000-fold concentrations and added in 0.01-ml volumes to each 10-ml culture flask. Results are the mean for at least three cultures in each set of conditions. At least 10 microscopic fields were scored for each culture. The cortisol concentration measured by radioimmunoassay in Manchester horse serum ($10.0 \mu\text{g ml}^{-1}$) did not differ significantly from that found in six lots of Rockville horse, fetal calf or goat serum (range 2.5–25 $\mu\text{g ml}^{-1}$). No difference was detected in corticosterone or Δ -aldosterone concentrations. These levels reflect total protein-bound and free corticosteroid. The biologically active unbound fraction was increased variably by addition of free steroid⁽¹⁵⁾. Results are for NIH/Swiss mouse marrow.

Enzyme replacement using liposome carriers in feline G_{M1} gangliosidosis fibroblasts

CURRENT emphasis in research on lysosomal storage diseases is directed towards enzyme replacement therapy (ERT) for these inherited enzyme deficiencies¹⁻³. The rationale for ERT is based on the assumption that endocytosed enzyme would enter lysosomes and function in the degradation of accumulated substrates. However, inactivation of enzyme, immunological reactions and low cellular uptake have prevented successful application of this promising approach to therapy. Circumvention of these limitations requires the use of carriers which protect and stabilise replacement enzyme while enhancing uptake and subcellular distribution²⁻⁵. We report here the use of lipid vesicles (liposomes)⁶⁻⁹ as carriers for replacement enzyme in feline G_{M1} gangliosidosis fibroblasts which have deficient β -galactosidase (β -gal) activity and lysosomal storage of glycopeptides⁹⁻¹¹. Our results demonstrate increased β -gal activity and corresponding catabolism of stored glycopeptides in feline G_{M1} gangliosidosis fibroblasts treated with liposomes containing β -gal.

Fibroblast cultures derived from skin of normal cats and cats with G_{M1} gangliosidosis were maintained in McCoy's 5a medium with 20% fetal calf serum¹². β -Galactosidase activity was determined with the fluorogenic substrate, 4-methyl-umbelliferyl- β -D-galactoside (4-MU- β -galactoside) (1 unit = 1 nmol substrate cleaved h⁻¹)^{10,13}, and protein was estimated by the

Fig. 1 Elution patterns of ¹⁴C-GP from a 0.9 × 100 cm BioGel P10 column. Homozygous dominant fibroblasts at: a, end of pulse and b, 240 h after pulse, and homozygous recessive fibroblasts at: c, end of pulse and d, 240 h after pulse. (4 ml fractions.)

method of Lowry¹⁴. Partially purified β -gal was obtained by concanavalin A chromatography of acetone-precipitated normal feline liver homogenate¹⁰. Large multilamellar liposomes (1,000-6,000 Å) containing β -gal [L(β -gal)] or thorium dioxide (L[thor]) were prepared from phosphatidylcholine, dicetyl phosphate and cholesterol in a molar ratio of 7:2:1 (refs 5-8). Emulsification of the lipids in 6 ml of aqueous β -gal or thorium dioxide in a bath-type sonicator produced liposomes containing 11-13% of the total aqueous solute.

Entrapment of solutes within aqueous interstices of liposomes was confirmed by chromatographic separation of liposomes from untrapped solute and by demonstration of latency of entrapped solutes⁸. The integrity of the liposomes during incubation with fibroblasts was demonstrated by similar analysis of spent culture fluid⁸. In all cases, there was retention of entrapped solutes within chromatographic fractions containing liposomes. Entrapped β -gal was shown to be latent until the liposomes were lysed with Trixon X-100.

Normal and G_{M1} gangliosidosis fibroblasts were incubated with 2 μ Ci ¹⁴C-galactose to label the endogenous glycopeptide pool^{11,15}. The degree of labelling and metabolic fate of ¹⁴C-galactose-labelled glycopeptides (¹⁴C-GP) were evaluated at 48-h intervals by chromatographic separation on BioGel P10. The elution patterns of ¹⁴C-GP from normal and G_{M1}

Fig. 2 Dynamics of ¹⁴C-GP metabolism in (●) homozygous dominant and (△) homozygous recessive fibroblasts following a 48-h pulse with 2 μ Ci ¹⁴C-galactose per mg protein.

gangliosidosis fibroblasts are shown in Fig. 1. Total ^{14}C -GP was expressed for each interval as d.p.m. ^{14}C per mg protein in fractions 5–11. In normal fibroblasts there was initial labelling of ^{14}C -GP followed by rapid catabolism and clearance of ^{14}C , reflecting normal β -gal activity. However, in G_{M1} gangliosidosis cells β -gal deficiency was expressed by retention of ^{14}C -GP (Fig. 2).

Uptake and intracellular fate of liposomes were evaluated by electron microscopy of fibroblasts which had been incubated with L[thor]. Monolayers were incubated with 2,000 μg liposomal lipid for 6 h, washed three times, detached with 0.25% trypsin, centrifuged and prepared for electron microscopy¹⁶. The intracellular accumulation of thorium dioxide within heterophagosomes and membranous residual bodies is shown in Fig. 3.

Fig. 3 Electron micrograph of a G_{M1} gangliosidosis fibroblast following incubation with L[thor] demonstrating the presence of thorium dioxide within the lysosomal apparatus of the cell (bar = 1.0 μm). Insert illustrates fusion between a secondary lysosome (L) containing Thorotrast and a membranous residual body (R) characteristic of G_{M1} gangliosidosis fibroblasts (bar = 0.1 μm).

The efficacy of ERT was evaluated by labelling G_{M1} gangliosidosis fibroblasts with ^{14}C -galactose as described above. After 48 h, each monolayer was treated with either L[β -gal] containing 3,000 units of β -gal activity and 2,000 μg liposomal lipid or 3,000 units of untrapped β -gal. Control samples consisted of untreated fibroblasts, fibroblasts treated with liposomes containing buffer, or fibroblasts treated with liposomes containing buffer plus untrapped β -gal (3,000 units). Treatments were repeated and samples collected in 48-h intervals. Changes in ^{14}C -GP were monitored as described above, and changes in enzyme activity were monitored by assay of cell lysates. Treatment with either unencapsulated β -gal or any of the control treatments had no effect on ^{14}C -GP storage. However, treatment with L[β -gal] resulted in clearance of >80% of ^{14}C -GP and increased β -gal activity to 70% of normal, reflecting uptake of approximately 10% of the total enzyme activity presented in liposomes (Fig. 4).

Characterisation of this *in vitro* system, in which the dynamics of naturally occurring lysosomal storage can be quantitated, provides a unique model for precise assessment of ERT. Endogenous storage material in feline G_{M1} gangliosidosis fibroblasts seems to be similar to that found in human G_{M1} gangliosidosis fibroblasts¹¹. This glycopeptide is structurally similar to storage material found in hepatocytes of human and feline G_{M1} gangliosidosis^{17,18}, suggesting a potentially meaningful analogy between *in vitro* and *in vivo* therapeutic trials.

The ultrastructure of cells treated with L[thor] confirmed the lysosomotropic effect of liposomes. Although fusion of liposomes with primary lysosomes has been documented previously⁸, this study clearly demonstrates fusion of liposomes with membranous residual bodies characteristic of many

Fig. 4 Effect of enzyme replacement therapy on ^{14}C -GP storage and β -gal activity of G_{M1} gangliosidosis fibroblasts treated with: ●, unencapsulated β -gal, or ○, △, L[β -gal]. Differences in ^{14}C -GP storage and β -gal activity of all control samples and samples treated with unencapsulated β -gal were not statistically significant.

lysosomal storage diseases. This observation is important evidence supporting the potential value of liposome carriers in the prevention and reversal of lysosomal storage.

Failure of fibroblasts treated with unencapsulated enzyme to increase enzyme activity or degrade accumulated substrate supports the contention that a carrier is needed to introduce therapeutic quantities of hydrolytically active enzymes. Furthermore, increased levels of appropriate enzyme activity and enhanced degradation of endogenously accumulated substrate clearly demonstrate the value of liposomes as carriers of replacement enzyme in the correction of a metabolic defect in fibroblasts.

Calcium and magnesium ions and the regulation of multiplication in normal and transformed cells

THE relative importance of Ca^{2+} and Mg^{2+} in the regulation of cellular multiplication and alteration of that regulation by viral transformation has recently become a subject of considerable interest¹⁻⁵. Extracellular Ca^{2+} and Mg^{2+} both have effects on metabolic parameters and macromolecular synthesis in cultured cells. Mg^{2+} , because of its substrate level intracellular concentration and its role in macromolecular synthesis and intracellular transphosphorylation reactions, has been suggested as a possible coordinate regulator of the positive pleiotropic response, a coordinated array of reactions associated with initiation of DNA synthesis and multiplication in cultured cells⁶⁻⁹. Ca^{2+} , on the other hand, has been suggested as a short term regulator of cell growth and function, largely on the basis of its tightly regulated low cytoplasmic concentration^{10,11}. In this report, we describe a kinetic analysis of the effects of extracellular concentrations of Ca^{2+} and Mg^{2+} on survival and multiplication of normal and transformed human cells in culture. We have found that cellular

multiplication rate (number of population doublings per unit time) and also cellular 'survival rate' (percentage survival divided by time) can be substituted in place of reaction rate in classical enzyme kinetic formulae (Fig. 1). Both responses exhibit saturation kinetics, with a transition from first order response to zero order, as the concentration of calcium, magnesium, or any other essential component of the culture medium is increased. Rate plotted against concentration yields the expected right rectangular hyperbola described by the Henri-Michaelis-Menten formulation, and the expected linear relation when plotted by the Lineweaver-Burke or van Hofstee methods. Linear regression of the Lineweaver-Burke double reciprocal plot yields from its intercepts a maximal rate for multiplication or survival (equivalent to V_{max} in classical enzyme kinetics) and a Michaelis-Menten constant (K_m), equal to the substrate (or ligand) concentration yielding a half maximal rate of multiplication or survival.

In order to apply Michaelis-Menten kinetic analyses to cellular multiplication and survival, we have made the following assumptions: (1) each substrate or ligand (S) interacts with sites on or in each cell (C) to form complexes (CS), operationally equivalent to the ES complex of first order enzymatic reactions; (2) although each cell may have many sites that form complexes with S, the interactions between these sites and S are such that

Fig. 1 Multiplication response of normal and transformed human lung fibroblasts to Mg^{2+} . *a*, Colony size: previously described procedures for clonal growth and measurement of colony size¹²⁻¹⁴ were used, with the modifications described below. The basal medium was MCDB 105 (ref. 14) with pantothenate supplied as a sodium salt (Sigma), and with calcium chloride and magnesium sulphate omitted. For these experiments the basal medium was supplemented with 1.0×10^{-3} M ultrapure grade $\text{CaCl}_2 \cdot 4\text{H}_2\text{O}$ (Alfa) and $250 \mu\text{g ml}^{-1}$ dialysed fetal bovine serum protein (FBSP)¹⁵. Ultrapure grade $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ (Alfa) was added as indicated. Polylysine-coated tissue culture Petri dishes were used for N-HLF¹⁶. Uncoated dishes were used for SV-HLF, whose multiplication is either unaffected or slightly inhibited by the basic polymer. Each 60-mm dish was inoculated with 100 cells and incubated for 14 d. ●, Normal cell data for MRC-5 (ATCC CCL 171) at passage 20. Similar results have also been obtained with WI-38 and FLOW-2000 cells. ○, Transformed cell data for SV40 virus transformed WI-38 (Subline 2RA, ATCC CCL 75 1). The size of the five largest colonies per plate was measured photometrically with an aperture of 7 mm for N-HLF and 4 mm for SV-HLF as previously described¹². We have shown experimentally by trypsinisation and direct cellular counting with a Coulter counter that the photometric measurement averaged over the five largest colonies per dish is linearly related to the total number of cells per Petri dish (the sum of all colonies) and to the number of cells per colony in the colonies that are measured. Thus, the photometric measure can be used as an accurate indicator of total multiplication during the incubation period. *b*, multiplication rate: During the observation periods used here (7–14 d), the increase in colony size is essentially exponential. The increase in $\log C$ against t , where C is colony size and t incubation period, measured either by photometric or direct counting methods has a linear correlation coefficient $> +0.93$ for any given set of experimental conditions during that time period. Experimental data were normally collected after 14 d of incubation to minimise error in measurement of very small colonies. Colony size in photocell units was converted to multiplication rate by the formula $r = 3.32(\log_{10} C_t - \log_{10} C_0)/t$ where r = cell generations (population doublings) per d, t = incubation period in d, 3.32 = reciprocal $\log_{10} 2$, C_t = colony size in photocell units at the end of t d, and C_0 = colony size in photocell units at time zero. C_0 is a general background constant determined by linear regression to $t = 0$ of a plot of $\log_{10} C$ against t . For N-HLF, $C_0 = 0.080$ photocell units, and for SV-HLF, $C_0 = 0.11$ photocell units. The experimentally determined multiplication rates (r) for the various concentrations of Mg^{2+} have been fitted to a right rectangular hyperbola according to the Henri-Michaelis-Menten formulation. *c*, Lineweaver-Burke double reciprocal plot of the data from *b*. Values for the Michaelis-Menten constant (K_m) corresponding to the concentration of Mg^{2+} yielding a half maximal multiplication rate, and for r_{max} are obtained from the intercepts as shown. The best linear fit to the data was determined by 'least squares' estimate. Experiments resulting in regression lines with linear correlation coefficient $< +0.80$ were rejected for use in these analyses. Errors in K_m and r_{max} were estimated by Gaussian analysis of variance based on single data points which were means of triplicate determinations. Standard errors between triplicate individual determinations are indicated in *a* and *b* for N-HLF. For N-HLF, $K_m = 4.8(\pm 1.6) \times 10^{-5}$ M, $r_{\text{max}} = 0.492 \pm 0.055$, and for SV-HLF, $K_m = 4.2(\pm 1.0) \times 10^{-6}$ M, $r_{\text{max}} = 0.425 \pm 0.010$ at $P = 0.05$. The transformation of data on colony size and incubation time to a rate function distinguishes this analysis from previous studies seeking to apply enzyme reaction rate kinetics to cellular growth response, in which the fraction of cells synthesising DNA was measured rather than actual cellular multiplication rates¹⁷.

Table 1 Interaction of Mg^{2+} and Ca^{2+} in multiplication of normal and transformed human lung fibroblasts

Mg^{2+} (M)	N-HLF		SV-HLF	
	$K_m^{Ca^{2+}}$ ($mol\ l^{-1}$)	r_{max} (cell generations per d)	$K_m^{Ca^{2+}}$ ($mol\ l^{-1}$)	r_{max} (cell generations per d)
10^{-3}	$1.2(\pm 0.70) \times 10^{-5}$ NS	0.433 ± 0.025 ($P < 0.001$)	$1.1(\pm 0.64) \times 10^{-5}$ ($0.05 < P < 0.10$)	0.412 ± 0.025 ($0.02 < P < 0.05$)
10^{-4}	$1.5(\pm 1.25) \times 10^{-5}$	0.314 ± 0.039	$1.7(\pm 1.4) \times 10^{-5}$	0.398 ± 0.022
Ca^{2+} (M)	$K_m^{Mg^{2+}}$		$K_m^{Mg^{2+}}$	
	$K_m^{Mg^{2+}}$ ($mol\ l^{-1}$)	r_{max}	$K_m^{Mg^{2+}}$ ($mol\ l^{-1}$)	r_{max}
10^{-3}	$3.9(\pm 0.32) \times 10^{-5}$ ($P < 0.001$)	0.463 ± 0.010 NS	$7.8(\pm 0.98) \times 10^{-7}$ ($P < 0.001$)	0.404 ± 0.010 ($P < 0.001$)
10^{-4}	$1.1(\pm 0.80) \times 10^{-4}$	0.481 ± 0.08	$3.3(\pm 0.83) \times 10^{-6}$	0.351 ± 0.022

Kinetic parameters for the stimulation of multiplication of N-HLF (WI-38, passage 20) and SV-HLF by Ca^{2+} and Mg^{2+} were determined for each ion as a function of the concentration of the other. The procedures were the same as described in Fig. 1. The concentrations of both ions were varied within a single series of assays using the same stock cultures, basal media and FBSP. Values $\pm 95\%$ confidence limits are indicated. The probability (P) that the difference between values is due to chance was determined by Student's t test and is indicated between rows. NS, not significant or $P > 0.10$.

formation of CS can be treated as a first order function of S; (3) for each substrate or ligand (S), the rate of cellular multiplication (or survival) when all other substrates or ligands are constant is a first order function of the concentration of the CS complex; (4) the concentration of S is large relative to the concentration of sites in or on the cells, such that formation of CS does not significantly alter S; (5) consumption of S is sufficiently small that its concentration is not altered significantly and rates can be considered uniform throughout the assay period; (6) the rate of equilibration among cells, S, and CS complex is rapid relative to the rate of cellular multiplication or other processes that affect the concentration of CS; and (7) in the case of cellular multiplication, it is also necessary to assume that all daughter cells are identical to the parental cells, and cells remain in an exponential pattern of multiplication with no significant differentiation or other forms of withdrawal from the cell cycle.

The experimental system used in these studies is clonal growth of human diploid fibroblast-like cells derived from fetal lung (WI-38, MRC-5 and FLOW-2000 are interchangeable and are referred to as N-HLF) and a comparable transformed line (SV40 transformed WI-38, referred to as SV-HLF). An optimised medium (MCDB 105 (ref. 14)) was used which has each of its components adjusted to the centre of the concentration range yielding a zero order response¹²⁻¹⁴. The volume of medium per cell is large, and direct analysis of used media has verified that the concentrations of essential components do not change significantly during the assay period. Thus, the system seems to satisfy the assumptions made, as will be described elsewhere.

For N-HLF, both Ca^{2+} and Mg^{2+} are absolute requirements for multiplication, even when the other is present in saturating amounts. The requirements for multiplication are much greater than those for survival (Fig. 2). In these experimental conditions, the $K_m^{Mg^{2+}}$ for survival is only 5-6% of that for multiplication, and no effect of Ca^{2+} on survival rate can be demonstrated (zero order response). However, we cannot conclude that no Ca^{2+} is needed for survival, as atomic absorption spectrometry shows that the 'calcium-free' test medium contains $1.5 (\pm 0.12) \times 10^{-5}$ M calcium as a contaminant. The comparable 'magnesium-free' medium contains $8.6 (\pm 0.46) \times 10^{-6}$ M magnesium. These amounts are not due to contaminants in the high purity calcium and magnesium salts (each of which contains less than 2 p.p.m. of the other) or in the dialysed serum protein ($250\ \mu g\ ml^{-1}$) used in the assay.

Transformation of N-HLF with SV40 reduces the $K_m^{Mg^{2+}}$ for multiplication to that required for maintenance of either the normal or transformed cell (Fig. 2). In contrast, the amount of extracellular Ca^{2+} required for a half maximal rate of multiplication ($K_m^{Ca^{2+}}$) is changed little by transformation. However, some multiplication of SV-HLF occurs in the absence of added calcium, which could reflect either the background Ca^{2+} contamination or a 'basal' growth rate that does not require

Fig. 2 K_m values for multiplication and survival responses of N-HLF and SV-HLF to Ca^{2+} and Mg^{2+} . K_m values were determined as described for Fig. 1. Responses to Ca^{2+} and Mg^{2+} were measured with $250\ \mu g\ ml^{-1}$ FBSP and 1.0×10^{-3} M of the other ion. Survival rate was determined by incubating 100 cells per 60-mm Petri dish in 5.0 ml of a medium that is not permissive for multiplication. After 4 d, the medium was replaced with a complete growth medium and the dishes were incubated for a further 10 d after which the colonies were fixed, stained and counted. The survival media were similar to the growth media described for Fig. 1, except that in place of FBSP they contained $80\ \mu g\ ml^{-1}$ delipidated FBSP¹⁸. Delipidation of FBSP removes or inactivates one or more factors that are essential for multiplication of both types of cells¹⁹. N-HLF will survive in MCDB 105 without proliferation in the total absence of serum-derived factors^{13,14}. However, survival of SV-HLF in the same medium requires serum-derived factors that are not inactivated by delipidation. Delipidated serum was used with both types of cells for uniformity. Survival rate (number of survivors divided by days in survival medium) was measured as a function of concentration of Ca^{2+} or Mg^{2+} (with the other at 1.0×10^{-3} M) and K_m values for survival were determined from Lineweaver-Burke double reciprocal plots. White bars, multiplication; shaded bars, survival. Each value represents mean $\pm$ s.e.m. of three independent determinations using different stock cultures, media and FBSP preparations. Under the experimental conditions, Ca^{2+} has no effect on survival rate of N-HLF, possibly because of a low background level of calcium in the basal medium (see text).

Ca^{2+} . Additional experiments in a cleaner background medium are needed to distinguish between these possibilities. In contrast to N-HLF, SV-HLF cells exhibit an easily measured survival response to Ca^{2+} which can be extrapolated to give a $K_m^{\text{Ca}^{2+}}$ of about 2.9×10^{-6} M. The $K_m^{\text{Mg}^{2+}}$ for survival is essentially unchanged by transformation.

In an attempt to determine whether Ca^{2+} or Mg^{2+} exerts the most proximal effect on cellular multiplication, we determined both K_m and $r_{\max}$ for each ion as a function of the other (Table 1). For N-HLF, the amount of Mg^{2+} in the medium has little effect on the amount of Ca^{2+} needed for a half maximal response ($K_m^{\text{Ca}^{2+}}$), but has a direct effect on the maximal growth response to calcium that can be obtained ($r_{\max}^{\text{Ca}^{2+}}$). Ca^{2+} , however, has no effect on the maximal growth that can be obtained ($r_{\max}^{\text{Mg}^{2+}}$), but low levels of calcium significantly increase the amount of magnesium needed for the response ($K_m^{\text{Mg}^{2+}}$). We interpret these results, in agreement with Rubin⁵, as indicating that for normal cells the role of Mg^{2+} is more proximal to the intracellular events that determine $r_{\max}$ for cellular multiplication than are those processes directly affected by Ca^{2+} .

In transformed cells, $r_{\max}$ values that can be achieved are affected less by Mg^{2+} , but seem to be dependent on Ca^{2+} . This observation is consistent with the interpretation that Mg^{2+} does not have a specific regulatory role in the multiplication of transformed cells and suggests that Ca^{2+} has the most proximal role in the multiplication of such cells. These striking and complex differences between normal and transformed HLF show the need for further investigation of the relationship.

In the presence of saturating amounts of Ca^{2+} and Mg^{2+} (10^{-3} M each), multiplication, but not survival, of N-HLF is dependent on serum macromolecules whose role is presumed to be regulatory¹⁴. To investigate the interactions among Ca^{2+} , Mg^{2+} , and serum-derived regulatory macromolecules, we determined K_m for both ions as a function of serum protein (FBSP) concentration in the medium (Fig. 3). K_m values for both ions tend to rise as FBSP concentration is reduced. However, at very low levels of FBSP, $K_m^{\text{Ca}^{2+}}$ rises very steeply, whereas $K_m^{\text{Mg}^{2+}}$ levels off, suggesting that Ca^{2+} may be the ion that interacts the more directly with serum macromolecules that exert multiplication-stimulating effects on normal cells.

Fig. 3 Effect of FBSP on apparent K_m for Ca^{2+} and Mg^{2+} for multiplication of N-HLF. Multiplication rate responses to Ca^{2+} and Mg^{2+} with the other at 1.0×10^{-3} M were measured at each of the indicated levels of FBSP and K_m values were determined in a single experiment as described in Fig. 1. The N-HLF stock culture used here was MRC-5 (passage 20). Vertical bars, s.e. due to the regression analysis. $\diamond$, $K_m^{\text{Ca}^{2+}}$; $\blacklozenge$, $K_m^{\text{Mg}^{2+}}$.

From these data we propose that (1) Ca^{2+} and Mg^{2+} have equally important roles in regulation of cellular multiplication that go beyond support of attachment and survival of non-proliferating cells; (2) transformation causes a selective loss of the regulatory role of Mg^{2+} , but not Ca^{2+} , in cellular multiplication; (3) in normal cells, Mg^{2+} has its regulatory effect on a process more proximal to the intracellular events of cellular replication than those processes affected directly by Ca^{2+} ; (4) in normal, but not transformed cells, the regulatory effect of Ca^{2+} is primarily mediated through Mg^{2+} -dependent processes; (5) the role of Ca^{2+} is more proximal than that of Mg^{2+} to the action of regulatory macromolecules from serum in the chain of events which ultimately determine multiplication rate of normal cells.

Does Ca^{2+} cause fusion or lysis of unilamellar lipid vesicles?

MEMBRANE fusion is the central event in biological processes as diverse as secretion, fertilisation, endocytosis and pathological cell fusion, but as yet its mechanism is poorly understood¹. To elucidate this mechanism, bilayer phospholipid vesicles have been used extensively as models for interacting biomembranes^{2–5}. As a result of studies involving differential scanning calorimetry and freeze-fracture electron microscopy, it has been suggested that vesicles made from acidic phospholipids can fuse when exposed to divalent cations^{3,6}. For phosphatidylserine vesicles, the 'critical' Ca^{2+} concentration for membrane fusion seems to be ~ 1 mM, at which concentration a drastic increase in the permeability of the vesicle membranes has also been reported³. The techniques used to demonstrate 'fusion' in this system do not exclude molecular mixing of interacting membranes by mechanisms other than genuine fusion. In the latter case, the membrane-bounded internal compartments of two separate vesicles must become confluent in a process which transfers the contents of the initial vesicles to the resulting vesicle. It is possible, however, that Ca^{2+} may cause rupture of the lipid vesicles, with subsequent reassembly of the membrane fragments to form larger non-vesicular structures. If this is occurring, bilayer vesicles are poor paradigms for biological

% of total radioactivity remaining associated with liposomes after incubation with divalent cations (mM) for 1 h. The higher divalent cation concentrations caused an increase in the size of lipid particles in the suspensions, preventing their passage through a Sephadex column. A Millipore filter (0.8 μm pore diameter) was mounted above the column and the sample to be eluted was pipetted on to it. The column eluant was treated similarly. Consequently, any lipid particles below the size limit of the filter appeared in the void volume and the eluant effectively washed any free sucrose from the larger particles trapped on the Millipore. Radioactivity remaining associated with the Millipore was counted after dissolving the filter in a Triton X-100-based scintillation mixture. A quenching correction was applied.

membrane fusion. One may predict the likelihood of vesicle fusion by calculating their energy of interaction due to electrostatic repulsion and electrodynamic attraction⁷. This approach shows that the addition of 1 mM Ca^{2+} to a suspension of phosphatidylserine vesicles is unlikely to reduce electrostatic repulsion between liposomes sufficiently for any but a fraction of the smallest ones to approach to 0.8 nm separation. This finding suggests that vesicles cannot approach closely enough to fuse and supports the notion that Ca^{2+} may initiate vesicle lysis and reassembly. We report here experimental support for vesicle lysis, based on the redistribution of a marker for the aqueous phase between vesicles and the external compartment on exposure to divalent cations.

Sonicated unilamellar vesicles were prepared from phosphatidylserine (Lipid Products, grade 1, >99% pure; stored before use in chloroform under nitrogen at -20°C) according to the methods of Papahadjopoulos *et al.*^{3,6,8-11}. The vesicles (10 μmol of lipid per experiment) were suspended in 2 ml of 100 mM NaCl containing 20 μCi of ^3H -sucrose (Amersham). One hour after sonication they were separated from untrapped sucrose by elution of the suspension through a Sephadex G-50 column. One 10-drop fraction (0.92 ml) representing the centre of the lipid peak was collected. This fraction was then exposed to a known final concentration of Ca^{2+} or Mg^{2+} for a further hour, after which the proportion of the total sucrose remaining associated with the lipid was estimated by eluting the sample from a second Sephadex G-50 column (the eluting medium contained divalent cations at the same concentration as in the sample) and determining the amount of radioactivity in each fraction using a liquid-scintillation counter. These amounts were then compared with the location of the lipid peak in the total elution profile, as determined by phosphate analysis (modification of the method described by Allen¹²).

Fig. 1 Elution of phosphatidylserine vesicles containing ^3H -sucrose from a Sephadex G-50 column (300 $\times$ 10 mm). The location of the lipid peak (■) was determined by phosphate analysis. Radioactivity (●) is expressed as c.p.m. $\times 10^{-3}$.

In the absence of divalent cations, most of the marker remained associated with the vesicles 1 h after the first gel filtration (Fig. 1). Exposure to increasing concentrations of Ca^{2+} or Mg^{2+} , however, brought about a progressive release of ^3H -sucrose from the liposomes (Table 1). Ca^{2+} was more effective than Mg^{2+} , a finding in agreement with the work of others¹³.

If this release was the result of a divalent cation-induced increase in vesicle membrane permeability, one would expect to be able to incorporate radioactive sucrose into previously unlabelled vesicles by exposing them to divalent cations. To test this, sonicated vesicles were prepared in the absence of ^3H -sucrose. 20 μCi of this radiochemical were then added to the samples immediately after sonication and the uptake of radioactivity into vesicles was assessed following exposure of the samples to Ca^{2+} or Mg^{2+} .

Without divalent cations, only 0.007% of the total marker became associated with the vesicles during the incubation (Fig. 2). Thus, very little sucrose had leaked into vesicles or been adsorbed on to their membranes. Furthermore, the presence of Ca^{2+} or Mg^{2+} hardly affected this uptake (Table 2). It might be argued that the results in Table 2 are artificially low due to the loss of vesicle-incorporated sucrose during the separation of the lipid from the external compartment by the filtration procedure (see legend to Table 1). To exclude this possibility, vesicles were prepared without ^3H -sucrose. This tracer was then added to the external compartment, followed by Ca^{2+} to a final concentration of 10 mM. After 1 h, non-incorporated sucrose was removed by gel filtration, eluting with divalent cation-free 25 mM EGTA.

Fig. 2 Elution of a suspension of phosphatidylserine vesicles with ^3H -sucrose in the external aqueous compartment from a Sephadex G-50 column. Symbols as in Fig. 1.

Chelating agents can halt the Ca^{2+} -induced leakage of $^{22}\text{Na}^+$ and $^{42}\text{K}^+$ from phosphatidylserine liposomes¹³; thus, any ^3H -sucrose which had diffused into vesicles during incubation with 10 mM Ca^{2+} would not be washed out during elution. Only 0.002% of the total sucrose became associated with the lipid, implying that the values in Table 2 are not erroneously low.

Permeability coefficients for phosphatidylserine membranes may be calculated from Tables 1 and 2. In the 10 mM Ca^{2+} case, the ratio of these coefficients for release/uptake is 144:1 (1,170:1 in the EGTA version of the experiment). Divalent cations therefore seem to be able to bring about leakage of ^3H -sucrose from phosphatidylserine vesicles but not into them. It is unlikely that Ca^{2+} or Mg^{2+} is able to open a unidirectional pore in membranes as relatively simple as those under consideration. The most probable explanation for these findings is

Table 2 Leakage of ^3H -sucrose into liposomes

	Ca^{2+}	Mg^{2+}
Control	—	0.007
0.1	0.019	0.038
1	0.004	0.032

% of total radioactivity becoming associated with liposomes after incubation with divalent cations for 1 h. The % of total radioactivity that might be expected to be captured if the liposomal internal space equilibrated with the external space = 0.486. Divalent cation concentrations are in mM.

therefore that divalent cations bring about the complete rupture of phosphatidylserine vesicles, with production of structures which have lost the form of closed vesicles. This conclusion suggests the need for caution in interpreting vesicle 'permeability increases' under the influence of agents other than Ca^{2+} and Mg^{2+} . Regarding membrane fusion, it seems that the Ca^{2+} -phosphatidylserine system is an inappropriate model for biological membrane interaction, as the final product of the reaction between these components is not vesicular, although some initial fusion may occur on addition of Ca^{2+} to the suspension. Identification of the factors essential to fusion must await the development of a reliable assay for the occurrence of this process in artificial membrane systems.

I thank Dr David Gingell and Mr Ian Todd for advice and discussions, Dr A. D. Smith and Sheryl Homa for providing the facilities for lipid phosphorus analysis, and the MRC for financial support.

Uptake of charged lipid vesicles by isolated tomato protoplasts

LIPID vesicles act as carriers of biologically active materials into animal cells¹⁻³. A similar role might be envisaged for vesicles, for example, in the introduction of foreign DNA into plant protoplasts in genetic modification experiments⁴, or in the initiation of virus infection in plant protoplasts⁵. The amount of DNA which enters fed protoplasts is difficult to determine as is the multiplicity of virus which initiates infection in the poly-L-ornithine (PLO) (ref. 5) and polyethylene glycol (PEG) (ref. 6) procedures. To overcome these limitations of existing methods for the introduction of materials into protoplasts, I report here a vesicle system with the potential to fuse with the negatively charged plasmalemma⁷. Single membraned ('hollow') vesicles were considered more suitable to combine membrane instability with large 'load' volume, required to facilitate carriage of large molecules/virus particles into the protoplast and to release their content synchronously within.

Tomato protoplasts were isolated as previously described⁸. Positively charged vesicles were prepared as follows: equal volumes of 10 μM lecithin and 1 μM stearyl amine were dissolved in chloroform-methanol (4:1, v/v) and evaporated to dryness⁹. The residue was resuspended at 2.5 mg ml^{-1} in phosphate buffered mannitol (PBM, 12% w/v mannitol in 50 mM sodium phosphate buffer, pH 7.0) containing 0.01% w/v fluorescein diacetate and shaken vigorously by hand to give vesicles of about 0.002-0.006 μm diameter. These were loaded with fluorescein diacetate to facilitate study. The vesicles were collected by centrifugation at 50 g for 10 min. Vesicles were washed by resuspension, recentrifugation in PBM. Small vesicles remained in the supernatant and were discarded.

Protoplast and vesicle counts were made and the populations mixed in the ratio of 1:1, protoplasts:vesicles, in a volume of 1 ml (1×10^6 protoplasts) of PMB. Samples were examined

Fig. 1 Uptake of charged vesicles by isolated tomato protoplasts. Top, binding of vesicles to the plasmalemma, arrows indicate binding of one or more vesicles per protoplast. Middle, uptake of vesicles into the central vacuole, indicated by arrow. In the adjacent protoplast, the vesicle is releasing its contents. Bottom, some protoplasts showing intense fluorescence in the central vacuole following release of the vesicle contents.

immediately after mixing and at 15 and 25 h after mixing. Incubation was in the dark at 25 °C. A random sample of 181 protoplasts examined immediately after mixing showed a total of 140 vesicles bound (Fig. 1, top). After 15 h, vesicles were detected in the central vacuole (Fig. 1, middle), no vesicles were detected in the medium or still adhering to the outer surface of the plasmalemma, nor was fluorescence detected in the medium. After 24 h, vesicles were no longer detected, but the vacuoles of many protoplasts were fluorescing (Fig. 1, bottom).

Further work is in progress to prepare vesicles with less stable membranes than those described here, which on fusion with the plasmalemma may release their contents directly into the cytoplasm. The present study suggests that charged vesicles may provide a method of introducing quantifiable amounts of materials into plant protoplasts.

Continuous production of monoclonal mouse IgE antibodies with known allergenic specificity by a hybrid cell line

SINCE the identification of IgE antibodies as mediators of allergic reactions by Ishizaka *et al.*¹ extensive work has been done to purify this new type of immunoglobulin from the serum of allergic patients and animals. However, all attempts so far have been limited by the very low serum concentration of these reaginic antibodies. This difficulty has been partly overcome with the detection of the extremely rarely occurring IgE-producing myelomas of the human² and the rat³, although IgE myelomas of other species are lacking. Moreover, none of the available IgE-myeloma proteins has a known allergenic specificity, which is indispensable for several important applications to future studies on the origin and mechanism of allergic processes. Here we describe a new murine cell line which is continuously producing high amounts of IgE antibodies with anti-ovalbumin (OA) specificity. This cell line was generated by cell fusion of murine myeloma cells with spleen cells from OA-hyperimmunised mice following the cell hybridisation technique developed by Köhler and Milstein⁴.

Table 1 PCA reaction of serum and ascites from IgE-14-205 tumour-bearing mice

Route of application	Time after inoculation (d)	Tumour rate	PCA titre Serum Ascites
Subcutaneous	8	5/5	8
	18	5/5	1,024
Intraperitoneal	8	4/5	32
	18	6/6	50,000 131,000
Intravenous	8	0/3	2
	22	2/3	3,000

Female BALB/c mice were inoculated with 5×10^5 hybrid cells from *in vitro* culture. log 2 dilutions of serum and ascites, 0.1 ml each, were injected intracutaneously at the back cover of male Wistar rats. After 48 h the animals were challenged with an intravenous injection of 0.5 ml 0.6% OA (5 times crystallised, Serva) in PBS containing 2% Evans blue. After 30 min the animals were killed. PCA titres are expressed as the reciprocal value of the highest dilution giving a PCA reaction.

The myeloma cell line P3-X63-Ag8, is an 8-azaguanine-resistant clone derived from the IgG1 (κ)-synthesising MOPC 21 myeloma of BALB/c origin. Spleen and mesenteric lymph-node cells for fusion were derived from female BALB/c mice immunised three to four times intraperitoneally at monthly intervals with 1–2 μ g of OA with Al(OH)₃ as described by Kulczycki *et al.*⁵. Three to seven days after the last immunisation spleen and mesenteric lymph-node cells were hybridised with P3-X63-Ag8 tumour cells at a ratio of 10:1 in the presence of 42% (w/v) polyethylene glycol (PEG), molecular weight 2,000 or 4,000, according to the method of Hämmerling⁶. The hybridised cells were resuspended in HAT medium (Dulbecco's modified medium supplemented with 10% heat-inactivated fetal calf serum, 5×10^{-3} M mercaptoethanol and hypoxanthine, aminopterin and thymidine⁷) and seeded at a density of 1×10^5 to 1×10^6 cells per well (serial dilutions) into multi-well tissue culture plates (Costar 3524). Because of the hypoxanthine guanine phosphoribosyl transferase (HGPRT)-deficiency of the P3-X63-Ag8 tumour cells, this HAT medium permits only growth of hybrid cells. Supernatants of wells containing hybrid clones were tested 3–5 weeks after cell fusion for IgE anti-OA antibodies, using the passive cutaneous anaphylaxis test of the rat (PCA) as described by Ovary⁸.

Table 2 Specificity for OA of antibody IgE-14-205

IgE supernatant	Allergen	PCA titre
+	OA	32
+	—	0
—	OA	0
+	BSA	0
Heat inactivated (2 h, 56 °C)	OA	0

For experimental detail see Fig. 1.

More than 2,000 individual hybrid cell lines were investigated. Only one of these was found to be positive in the PCA test. This hybrid cell line was found in a culture plate with vigorous cell growth in all wells, suggesting the presence of several hybrid clones in each.

The cells of this culture were therefore recloned several times by serial dilutions in Costar plates. A single PCA-positive clone from a culture plate with cell growth in less than 30% of all wells was chosen and recloned three more times by the same procedure, resulting in 100% PCA-positive subclones. A particular subclone (IgE-14-205) was selected for further propagation in spinner cultures.

The IgE anti-OA production was continuously controlled by the PCA reaction and it has now persisted for more than 8 months. The PCA titre of cell culture supernatants ranged between 1:64 and 1:256. The hybrid clone IgE-14-205 could also be propagated *in vivo* in adult BALB/c mice after subcutaneous or intraperitoneal inoculation of 5×10^5 hybrid cells (Table 1). Large quantities of IgE anti-OA antibodies were produced *in vivo*, especially by intraperitoneally growing tumours. The PCA titres ($>100,000$, see Table 1) by far exceeded those which can be reached by hyperimmunisation of mice.

The following findings demonstrate that antibody IgE-14-205 belongs to the IgE class and behaves like a typical murine reaginic antibody. (1) After heating to 56 °C for 2–4 h, IgE-14-205 cell culture supernatants had completely lost their skin-sensitising capacity (Table 2). This finding is consistent with the well known thermolability of IgE antibodies⁹, which is in contrast to all other immunoglobulin classes. (2) Sheep anti-rat IgE antiserum (Miles) in the Ouchterlony immunodiffusion test¹⁰ gives a single precipitation band against serum and ascites of IgE-14-205 tumour-bearing mice (data not shown). Moreover, the skin-sensitising capacity of IgE-14-205 cell culture supernatants could be removed by *in vitro* preincubation with this antiserum and subsequent centrifugation (Fig. 1). (3) Antibody IgE-14-205 shows no immunological crossreactivity

Fig. 1 Specificity of antibody IgE-14-205. PCA reaction of antibody IgE-14-205 was measured after preincubation of cell culture supernatants (24 h at 4 °C) with equal parts of log 2 dilutions of a, OA (1,000 to 32 μ g ml⁻¹ PBS); b, sheep anti-rat IgE (undiluted to 1:32 in PBS); c, BSA (1,000 to 32 μ g ml⁻¹ PBS). After preincubation the samples were centrifuged for 10 min at 10,000 r.p.m. and the supernatants were tested in the PCA. The PCA reaction was quantitated by extracting the blue skin plaques and measuring the extinction at 623 nm (= PCA units) as described by Spector¹¹. Each supernatant was tested in duplicate. The control supernatant was diluted 1:2 with PBS.

Table 3 Passive peritoneal anaphylaxis of the rat

Experimental group	No. of animals	Histamine release (IU)	(%)
Control with IgE	8	1.58 ± 0.31	100
Control without IgE	9	0.57 ± 0.05	0
5 mg per kg DSCG	5	0.74 ± 0.19	17

Male Wistar rats were injected intraperitoneally with 2 ml 1:5 diluted ascites from IgE-14-205 tumour-bearing mice (PCA titre 3,000). After 2 h 1 ml DSCG in PBS (5 mg per kg body weight) and 30 s later 5 ml OA in PBS (0, 4 mg ml⁻¹) containing 50 µg ml⁻¹ heparin were given intraperitoneally. After 5 min the animals were killed and the histamine content of the cell-free peritoneal exudate was estimated according to the method of Shore¹⁴. The animals of the negative control group received PBS instead of the IgE-ascites. IU, spectrofluorimetric intensity units.

with murine IgG2a, IgG2b, IgG3 and IgA (data not shown). It has a molecular weight of about 200,000, estimated by Sepharose-6B electrophoresis. (4) The allergenic specificity for OA of antibody IgE-14-205 was established by the demonstration that IgE antibodies from IgE-14-205 cell culture supernatants could be neutralised *in vitro* in a dose-dependent manner with OA but not with bovine serum albumin (BSA) (Fig. 1). In agreement with this finding is the observation that IgE-14-205 supernatants failed to produce a PCA reaction when either the related allergen (OA) was omitted or when an unrelated allergen such as BSA was used (Table 2). (5) When IgE-14-205 cell culture supernatants or serum and ascites from IgE-14-205 tumour-bearing mice were tested on rats, OA-specific PCA was observed. This result agrees with the well established cross reactivity of mouse and rat IgE antibodies with rat mast cells. Histologically, the PCA reaction in the rat was found to be a typical allergic reaction, with subcutaneous mast cell degranulation and dilatation of small blood vessels without any signs of a nonspecific inflammatory process. (6) Histamine release from peritoneal rat mast cells was induced in the passive peritoneal anaphylaxis test in rats¹² by serum and ascites from IgE-14-205 tumour bearing mice (Table 3). This allergic mediator release could be inhibited by anti-allergic drugs. Thus histamine release was almost completely blocked by 5 mg per kg body weight disodium cromoglycate (DSCG, Fisons) (Table 3).

In conclusion, the results described here confirm that the IgE-14-205 cell line represents a hybrid cell line which secretes OA-specific antibody of the IgE class. In addition to the reagenic antibody, the original hybrid cell line IgE-14-205 secretes the IgG1 (κ) immunoglobulin of the tumour P3-X63-Ag8, demonstrated in the Ouchterlony test with a rabbit anti-mouse IgG1 antiserum (Nordic). However, we have now selected two sublines which are highly active in secreting the reagenic antibody without any detectable IgG1 (κ) immunoglobulin in cell culture supernatants (data not shown).

Thus, the described hybrid cell line is the first tumour cell line which is continuously synthesising murine reagenic antibodies. It enables the production of murine IgE for various immunological, allergological and genetic studies, which have hitherto been extremely difficult¹³. Furthermore, antibody IgE-14-205 is the first available monoclonal IgE with known allergenic specificity. The murine hybrid cell line IgE-14-205 will be available on request exclusively for scientific purposes.

We thank Dr C. Milstein for the myeloma P3-X63-Ag8, and Mrs M. Ulrich and Mrs Ch. Schneider for technical assistance.

Heavy HLA-DR (Ia) antigen chain is controlled by the MHC region

THE major histocompatibility complex (MHC), called the *HLA*-region in man and the *H-2* region in the mouse, contains many genes controlling an array of immunobiological phenomena. Thus certain parts of the immune response and various cell-cell interactions in normal immune processes are under genetic control from the MHC². Two structurally distinct groups of cell surface glycoproteins have so far been identified as products of genes localised to the MHC. The *HLA-A*, *B* and *C* loci control the expression of dimeric molecules composed of dissimilar subunits^{3,4}. The small subunit, β₂-microglobulin, is invariant and its structural gene resides on chromosome 15⁵. The large subunit carries the alloantigenic determinants which show that the *A*, *B* and *C* loci most probably harbour the structural genes for these polypeptide chains. The *HLA-D* locus also controls expression of cell surface antigens which are composed of two types of dissimilar subunits, and seem to be the human counterparts to murine Ia antigens⁶⁻⁹. Neither in man nor in the mouse have unambiguous data been provided demonstrating whether only one or both *HLA-D* (Ia) antigen subunits express the particular allotypic determinants. However, Barnstable *et al.*¹⁰ approached this problem by using the somatic cell hybridisation technique and provided evidence suggesting that at least the large, 35,000 molecular weight *HLA-D* antigen subunit is controlled by the MHC. In this note we demonstrate that by serological analyses and peptide mapping experiments the 35,000 MW *HLA-D* antigen chain is a product of the *HLA-D* locus.

HLA-D antigens were isolated from leukaemia cells of a patient suffering from chronic lymphatic leukaemia, as will be described elsewhere (L.K. *et al.* in preparation). The isolated *HLA-D* antigens were of high purity as revealed by SDS-polyacrylamide gel electrophoresis, gel chromatography, ultracentrifugation and immunological analyses. The *HLA-D* antigen phenotype of the patient, from whom cells were derived, was Dw3 and Dw4 as assessed by tissue typing techniques¹¹. The highly purified *HLA-D* antigens reacted with alloantisera directed against Dw3 and Dw4 but not with an alloantiserum directed against Dw2.

To establish which of the two *HLA-D* antigen subunits reacts with the alloantisera, ¹²⁵I-labelled¹² *HLA-D*-antigens were subjected to isoelectric focusing (Fig. 1). The material resolved into three main radioactive peaks, material from the peaks was extracted with a Tris-buffer containing Triton X-100 and aliquots were subjected to SDS-polyacrylamide gel electrophoresis¹⁴. The most acidic and basic fractions comprised the two *HLA-D* antigen subunits in highly purified form. The intermediate peak (c in Fig. 1) varied in size in different experiments. The observation that the amount of this material was inversely proportional to the amounts of the acidic and basic

components together with the SDS-polyacrylamide gel electrophoretic profile strongly suggest that the intermediate material (peak c) represents undissociated *HLA-D* antigen.

The separated subunits and the intact, radioactively labelled *HLA-D* antigens were treated with various alloantisera and heteroantisera in indirect immunoprecipitation assays¹⁵ to elucidate their antigenic properties. Table 1 summarises the results. The rabbit antiserum against *HLA-D* antigens¹⁵ reacted well with the intact *HLA-D* antigens as well as with the isolated subunits whereas the antiserum raised against *HLA-A, B* and *C* antigens³ did not react significantly better than normal rabbit serum. The alloantisera did not react as well with the intact *HLA-D* antigens as the rabbit antiserum, but it is obvious that each alloantiserum only recognised a subpopulation of the isolated *HLA-D* antigens as the combination of alloantisera precipitated about as much *HLA-D* antigens as the sum of the individual alloantisera. Alloantiserum directed against the specificity Dw2 did not react with the *HLA-D* antigens which

Fig. 1 Isoelectric focusing of highly purified ¹²⁵I-labelled *HLA-D* antigens. The labelled antigens were treated with 9 M urea in a buffer containing 2% Ampholines 3.5–10 (LKB) and 2% Triton X-100 for 2 h. The material was then subjected to isoelectric focusing¹³ in a 6% polyacrylamide gel containing 1%, pH 3.5–5, 1%, pH 5–8, and 0.5%, pH 3.5–10. Ampholines, 0.3 M sucrose, and 2% Triton X-100. After completed separation the gel was sectioned in an automatic gel slicer. Fractions containing radioactivity were pooled as indicated in the figure (b–d) mixed with 0.2 ml of 0.02 M Tris-HCl buffer, pH 8.0, containing 0.15 M NaCl and 0.5% Triton X-100, and gently agitated for 12 h to extract the radioactive material. Polyacrylamide was then removed by filtration over glass wool, and the radioactive materials were subjected to dialysis against the Triton X-100-containing Tris buffer. Aliquots from the three fractions were subsequently subjected to SDS-polyacrylamide gel electrophoresis¹⁴ (b–d). The arrows denote the migration positions of marker immunoglobulin G heavy and light chains and the tracking dye.

Table 1 Immunological reactivity of *HLA-D* antigens and their isolated subunits

Antiserum*	<i>HLA-D</i> antigens	28,000 MW	35,000 MW
		chain	chain
		% precipitated	
R α <i>HLA-D</i>	90	65	54
R α <i>HLA-A, B, C</i>	2	3	2
NRS	3	1	1
Dw3	34	4	16
Dw4	24	3	10
Dw3 + Dw4	52	3	21
Dw2	3	1	2
NHS	2	2	1

The ¹²⁵I-labelled *HLA-D* antigens and the separated subunits were incubated with 25- μ l portions of the alloantisera or 3- μ l portions of the rabbit sera as indicated above. After 5 h at room temperature immune complexes and free immunoglobulins were precipitated¹⁶. The precipitates were washed three times with ice-cold saline and subjected to SDS-polyacrylamide gel electrophoresis to establish subunit composition. The radioactivity in the precipitated proteins was measured. The data represent a typical experiment. Variations in the amount of radioactivity precipitated with the various antisera were noted in different experiments, although the data were qualitatively identical. Preliminary analyses suggest that the immune reactivity of the *HLA-D* antigens and the isolated subunits depends on the iodination conditions and the time spent in the urea-containing buffer.

The designations for the sera are: R α *HLA-D*, rabbit antiserum against *HLA-D* antigens; R α *HLA-A, B, C*, rabbit antiserum against *HLA-A, B, C* antigens; NRS, normal rabbit serum; Dw2, Dw3, Dw4, alloantisera against antigenic specificities Dw2, Dw3 and Dw4 respectively; NHS, normal human serum. The alloantisera were monospecific as determined by their reactivity in tissue typing experiments with use of the same target cells as used in the VII Histocompatibility Testing Workshop (Oxford). Their local designations are 3082B (Dw2), 4551 (Dw3) and 2503C (Dw4).

agrees with the results of the tissue typing (see above). Neither of the alloantisera recognised the 28,000 MW subunit whereas both antisera precipitated significant amounts of the 35,000 MW chain. The reactivity of the anti-Dw4 serum was considerably weaker than that of the anti-Dw3 serum. This observation is in part explained by the differences in titre between the two sera but the urea treatment used during the isolation procedure for the subunits may have deranged the Dw4-expressing *HLA-D* antigens more than the Dw3-expressing ones.

The lack of reactivity of the alloantisera against the 28,000 MW *HLA-D* antigen subunit may have depended on this chain being more sensitive towards denaturants than the 35,000 MW chain. This possibility had to be considered although the rabbit antiserum reacted well with the isolated 28,000 MW chain in as much as alloantigenic determinants may reside in limited parts of the chain. Further attempts to document an allotypic variation also for the 28,000 MW subunit were therefore made. ³H-Tyrosine-labelled *HLA-D* antigens were isolated by indirect immunoprecipitation¹⁶ using rabbit anti-*HLA-D* antigen serum. The sources of *HLA-D* antigens were the lymphoblastoid cell lines Daudi and Raji, which display the *HLA-D* phenotype Dw6/unidentified and Dw3/Dw6 respectively (C. Barnstable, personal communication). The *HLA-D* antigen subunits were separated by SDS-polyacrylamide gel electrophoresis. By running the electrophoresis in the absence of reducing agents a complete separation between the two subunits was obtained (compare ref. 7). The two types of subunits were separately extracted from the gel, digested with trypsin and subjected to peptide separation by high-pressure liquid chromatography. The sensitivity and reproducibility of this method makes it well suitable for the fractionation of radiochemical amounts of peptides and it has recently been used effectively for the isolation of peptides derived from trace amounts of *HLA-A* and *B* antigens (L.R., J.F. and P.A.P., in preparation). Figure 2 shows the results of the peptide separations. In analogy with the serological analyses described above

the 35,000 MW subunits derived from the Daudi and Raji cells displayed clearly discernible peptide differences. However, the peptide patterns recorded for the 28,000 MW chains were very similar. As can be seen in Fig. 2 the two types of *HLA-D* antigens subunits from a single cell line did not exhibit peptide patterns that argue for any obvious identity in primary structure. Since the procedure for the peptide mapping experiments was very reproducible it seems reasonable to conclude that the Daudi and Raji cell lines express very similar if not identical 28,000 MW *HLA-D* antigen subunits, whereas the 35,000 MW chains have different primary structures.

The data presented here, together with those of Barnstable *et al.*¹⁰, seem to establish that the large *HLA-D* antigen subunit by serological, structural and genetical evidence is derived from the MHC. By the same criteria there is no evidence to suggest that the small *HLA-D* antigen chain is coded for by the same genetic region. However, the I-region of the mouse controls the expression of *HLA-D* antigen analogues (the Ia antigens) from at least two loci, *A* and *E/C*¹⁷. Limited amino acid sequence analyses

demonstrated that both Ia-antigen subunits may be derived from the MHC^{18,19}. Further work is therefore needed to clearly demonstrate that the small *HLA-D* antigen subunit is not a product of the *HLA-D* locus.

We thank Ms Inga Sjöquist for technical assistance and Dr J. B. Lindblom for alloantisera. This work was supported by grants from the Swedish Cancer Society, Gustaf V:s 80-års fond, and Svenska Livförsäkringsbolagens fond för medicinsk forskning.

Fig. 2 Peptide patterns of ³H-tyrosine labelled *HLA-D* antigen subunits derived from Daudi and Raji cells. The labelled cells were washed, treated with 1% Triton X-100 in 0.02 M Tris-HCl buffer, pH 8.0, and the glycoproteins were isolated by affinity chromatography¹⁶. *HLA-D* antigens were isolated by indirect immunoprecipitation and immune complexes were separated by SDS-polyacrylamide gel electrophoresis¹⁴ in the absence of reducing agents. After segmentation of the gels the well-resolved *HLA-D* antigen subunits were extracted from the gel pieces essentially as described in Fig. 1. After the extraction remaining polyacrylamide gel was removed by filtration over glass wool. Human IgG (100 µg) was then added to each pool which was subjected to extensive reduction and alkylation. Excess reagents and SDS was removed by gel filtration on columns of Sephadex G-25 equilibrated with 0.02 M NH₄HCO₃. After lyophilisation the samples were taken up in 0.4 ml of 0.2 M NH₄HCO₃ containing 10 µg of trypsin. The digestions were terminated by lyophilisation after 3 h at 37 °C. The tryptic digests were finally dissolved in 50 µl of 0.05 M ammonium acetate, pH 4.5, containing 6% acetonitrile and subjected to high pressure liquid chromatography (Waters Associates). The C-18 column was operated at 50 °C. Elution was performed with a 60-ml linear gradient of acetonitrile, 6% to 40%, in the ammonium acetate buffer. Fractions of 0.3 ml were collected at 20 s intervals. a, Daudi 28,000 MW chain; b, Raji 28,000 MW chain; c, Daudi 35,000 MW chain; d, Raji 35,000 MW chain.

9,11-Epoxyiminoprostano-5,13-dienoic acid is a thromboxane A₂ antagonist in human platelets

THROMBOXANE A₂ (TXA₂), an important arachidonic acid metabolite, aggregates platelets¹⁻⁶, constricts coronary smooth muscle^{1,7,8}, and is formed during mechanical or anaphylactic organ challenge⁹⁻¹¹. There are selective thromboxane A₂ synthetase inhibitors¹²⁻¹⁶ but there are no known, selective TXA₂-receptor antagonists. We report here that 9,11-epoxyimino-prostano-5,13-dienoic acid¹⁷ (9,11-EIP) antagonises TXA₂-mediated platelet aggregation without inhibiting thromboxane synthetase or fatty acid cyclo-oxygenase. This finding should allow further exploration of the nature of TXA₂ receptors in human platelets.

The fatty acid cyclo-oxygenase enzyme transforms arachidonic acid into prostaglandin (PG) endoperoxides (PGG₂, PGH₂)^{18,19}, which aggregate platelets either directly^{20,21} or after conversion to TXA₂^{1,4,22}. Platelet-rich plasma (PRP) and washed platelet suspensions containing 9,11-EIP were challenged with the following stimuli: arachidonic acid, PGH₂, TXA₂ generated *in vitro* by platelet microsomes⁴ and a sub-aggregatory dose of PGH₂, PG endoperoxide analogues^{23,24}, adrenaline or ADP. The aggregation profiles elicited by these agents were subsequently monitored. TXB₂ and PGE₂ concentrations during aggregation were quantitated by radioimmunoassay^{25,26}.

9,11-EIP suppressed TXA₂-induced aggregation of PRP in a dose-dependent manner (Fig. 1) with 50% inhibition occurring at <200 ng ml⁻¹. 9,11-EIP did not inhibit TXA₂ formation, because the TXA₂ was generated *in vitro* and added after its

formation. The results were identical in platelets treated with cyclo-oxygenase inhibitor (1×10^{-4} flurbiprofen), ruling out any contributions from the release of endogenous arachidonic acid metabolites. 9,11-EIP also antagonised aggregation induced by PG endoperoxide analogues^{23,24} (Fig. 2).

9,11-EIP suppressed PGH₂- and arachidonic acid-induced platelet aggregation in a dose-dependent manner at concentrations which did not affect TXB₂ levels (Fig. 3). PGE₂ and cyclic AMP levels were also unchanged (data not shown). Selective thromboxane synthetase inhibitors divert PGH₂ metabolism towards the formation of the bis-enoic prostaglandins, some of which, for example, PGD₂, can oppose aggregation by elevating cyclic AMP²⁵. Therefore, 9,11-EIP blocked aggregation independently of two common anti-aggregatory mechanisms, TXA₂ synthetase inhibition and cyclic AMP elevation²⁶. Results were similar in PRP. 9,11-EIP suppressed arachidonic acid- or PGH₂-induced aggregation in a dose-dependent manner at concentrations which did not affect TXB₂, PGE₂ or cyclic AMP levels. 9,11-EIP did not affect the first wave, but it suppressed the second wave of adrenaline- and ADP-induced aggregations, revealing its specific involvement with the arachidonic acid

Fig. 1 Effect of 9,11-EIP on TXA₂-induced aggregation of human PRP. PRP was prepared by centrifuging fresh, human whole blood (1 part 3.8% citrate/9 parts blood) at 200g for 10 min at 25 °C. TXA₂ was generated by incubating a sub-aggregatory concentration of PGH₂ (200 ng) with flurbiprofen-treated human platelet microsomes⁴ suspended in Tris buffer, pH 8.0 (20 µl containing 1 mg protein), for 20 s at 37 °C inside an aggregometer cuvette. PRP, preincubated at 37 °C for 2 min with 9,11-EIP was added to the cuvette containing TXA₂. The PRP was stirred at 1,100 r.p.m. at 37 °C and the aggregation profile was monitored with a Payton single-channel aggregometer. Increasing concentrations of 9,11-EIP suppressed TXA₂-induced aggregation in a concentration-dependent fashion. Effects from TXA₂ synthetase inhibition were precluded, as TXA₂ was generated *in vitro* before the addition of PRP and results were identical with PRP treated with 10^{-4} M cyclo-oxygenase inhibitors (aspirin, flurbiprofen). Results are consistent with TXA₂ antagonism. a, Control; b, 125 ng ml⁻¹; c, 250 ng ml⁻¹; d, 500 ng ml⁻¹; e, 2,500 ng ml⁻¹, 9,11-EIP.

Fig. 2 Effect of 9,11-EIP on endoperoxide analogue-induced aggregation of human PRP. The conditions were similar to those of Fig. 1 except the endoperoxide analogues, 9,11-azido-15(S)-hydroxyprosta-5,13-dienoic acid (50 ng ml⁻¹) (A) or 9,11-methanoepoxy-15(S)-hydroxyprosta-5,13-dienoic acid (250 ng ml⁻¹) (B), were used so as to induce aggregation instead of TXA₂. The quantitatively different response of the antagonist against these analogues may reflect the fact that 9,11-azido-15(S)-hydroxyprosta-5,13-dienoic acid 'resembles' TXA₂ more than does 9,11-methanoepoxy-15(S)-hydroxyprosta-5,13-dienoic acid. A: a, control; b, 50 ng ml⁻¹; c, 100 ng ml⁻¹; d, 150 ng ml⁻¹; e, 300 ng ml⁻¹ 9,11-EIP. B: a, control; b, 250 ng ml⁻¹; c, 1.0 µg ml⁻¹ 9,11-EIP.

pathway. At concentrations exceeding 5×10^{-5} to 1×10^{-4} M, 9,11-EIP inhibited the platelet cyclo-oxygenase, reducing both TXB₂ and PGE₂ synthesis.

Needleman *et al.*²⁰ proposed that thromboxanes have at least two unique but dissociated properties, rabbit aorta constriction and platelet aggregation. The results with 9,11-EIP conditionally support this proposal. Although 9,11-EIP antagonises platelet aggregation, apparently by direct TXA₂-receptor blockade, it has intrinsic agonist properties for coronary smooth muscle, constricting the rat aorta and thereby preventing an assessment of any accompanying TXA₂ antagonism in this system. 9,11-EIP also inhibits PGI₂ formation in rabbit lung microsomes and BALB 3T3 cells at 10^{-5} M. Nevertheless, the thromboxane pathway dominates arachidonic acid metabolism in human platelets. TXA₂-receptor antagonists should further clarify the role of TXA₂ in platelet aggregation.

Conclusions on the role and mechanism of action of TXA₂ are frequently drawn by comparing the effects of selective inhibitors on the synthesis of arachidonic acid metabolites, modulation of cyclic AMP metabolism, and the attendant TXA₂-mediated physiology. As these inhibitors are only relatively selective³⁰, the conclusions are tentative and subject to re-evaluation. A TXA₂ antagonist is vital for further elucidation of the biochemical, pharmacological and physiological aspects of the arachidonic acid cascade in human platelets. 9,11-EIP is such an antagonist, with effects distinct from TXA₂ synthetase inhibition. Just as experiments with dichloroisoproterenol³¹ advanced the understanding of the β -adrenergic receptor, we believe that experiments with 9,11-EIP will advance the understanding of the TXA₂ receptor in platelets.

In summary, 9,11-EIP inhibited TXA₂-induced platelet aggregation in a dose-dependent manner. This inhibition was not due to an effect on TXA₂ synthetase because TXA₂ was generated *in vitro* before addition of PRP. 9,11-EIP also suppressed arachidonic acid- and PGH₂-induced aggregations of washed platelet suspensions and PRP without altering TXB₂,

Fig. 3 Washed platelets were prepared according to Miller *et al.*²⁷. PGH₂ was prepared according to Gorman *et al.*²⁹. Platelet suspensions were incubated with 9,11-EIP for 2 min at 37 °C. The platelet suspension was then transferred to an aggregometer cuvette containing PGH₂ (0.20 µg) or arachidonic acid (1 µg) (upper graphs) or arachidonic acid (1 µg) (lower graphs). The suspension was stirred at 1,100 r.p.m. at 37 °C; aggregation profiles were monitored and samples (0.1 ml) were withdrawn for the radioimmunoassay of TXB₂. 9,11-EIP suppressed aggregation in a dose-dependent fashion without inhibiting TXA₂ or PGE₂ formation. The open circles represent TXB₂ levels. PGE₂ levels (data not shown) ranged over 0.10–0.50 ng ml⁻¹. Upper graphs, a, control; b, 0.40 µg ml⁻¹; c, 0.60 µg ml⁻¹; d, 1.0 µg ml⁻¹ 9,11-EIP. Lower graphs, a, control; b, 0.08 µg ml⁻¹; c, 0.80 µg ml⁻¹; d, 2.0 µg ml⁻¹ 9,11-EIP.

PGE₂ or cyclic AMP levels. These results are consistent with antagonism of TXA₂ in platelets at the receptor level. Note that others have discovered selective prostaglandin antagonists^{32–34}.

Saccadic eye movements and visual stability

WE rarely confuse motions of our retinal images that result from movements of objects with those that result from eye movements. A predominant explanation of the perceptual stability that survives saccadic eye movements is that visual information about image movement is weighed against an internal ('extraretinal') signal about eye movement, and that a mismatch is generally perceived as movement of the world¹. Accurate information about eye position, even during a saccade, seems to be available to the oculomotor system^{2,3}, but it is not clear that this information finds its way to mechanisms underlying perceptual stability. The experiments we describe here show that errors in localisation following saccades are matched closely by errors in the size of saccades. We infer from this that the perceptual system does not monitor the extent of a saccade but merely assumes that an intended eye movement was made correctly.

The observer sits in a completely dark room with his head held steady by a dental impression. Ahead of him is an oscilloscope with an aluminised screen (P31 phosphor) on which appears a sharp, bright fixation spot (more than 2 log units above foveal threshold) and diameter 2–4 arc min, depending on viewing distance), with no surrounding glow. After 2.4 s this spot moves instantaneously a fixed distance to the left or right, where it remains for 100 ms before being extinguished. The direction of step is unpredictable to the observer, who tries to re-fixate the target, but this is extinguished before an eye movement can begin⁴ and so the saccade is made in the dark. 500 ms after extinction of the target, and after the saccade has been completed, a 'probe' spot appears for 500 ms at one of several fixed points about the target position, and the observer indicates with a keyswitch whether that spot lies to the left or to the right of the target.

This cycle is controlled by a computer and is repeated many times, with the direction of the target step and the position at which the probe spot appears, varying randomly from trial to trial. In a normal experimental session 350 trials are run in which the target steps to the right or left with approximately equal frequency, and for each direction of step the probe may appear in one of seven positions around the target position. From this we are able to plot two graphs, one for leftwards displacements, the other for rightwards, showing the relative frequency with which the probe in its various positions appeared to the left or right of the target. One such pair of graphs is shown in Fig. 1, for a target that stepped either 3.3° to the left (filled circles) or right (open circles). The smooth lines drawn through the points are the maximum likelihood estimates of the probit regression lines⁵

(the fits of which were rejected at the 10% level of significance in only three cases out of 21) from which one can obtain estimates of the mean and standard deviation of the distribution of judgements. The standard deviation of judgements is about 12 arc min, and the constant error, also about 12 arc min, is such that after a saccade the peripheral target seems to have moved further away from the fixation spot.

These errors, although small, are very reliable and indicate that in an impoverished environment the observer is not fully able to compensate for image displacements that result from saccades. The constant errors described here are a little smaller than those found by Monahan⁶ and Matin⁷ and much smaller than errors found by Bridgeman *et al.*⁸ in experiments to investigate perceptual mislocations related to saccadic eye movements; the task of subjects in the latter experiment was quite unlike that used here, which may explain the disagreement.

Fig. 1 Frequency with which the probe spot was judged to lie to the right of the target position (0 on the abscissa). The abscissa indicates probe position relative to the target. ● judgements made when a saccade followed a step of 3.3° to the left; O, corresponding judgements made following a step to the right. Smooth curves are maximum likelihood estimates of the probit regression lines. Each curve is based on an average of 175 trials in a single session, during which the probe appeared randomly at one of seven positions around the target point (observer P.L.).

Constant errors might have arisen because the initial target step was underestimated, although the saccades were made accurately to the (mislocated) target, or the saccade to the correctly located target may have been supposed accurate when in fact it fell short. Variability is probably due principally to two sources: first, the target is seen (initially) in peripheral vision, so its visual direction is to some extent uncertain. Moreover, the observer has to remember this direction during the 500 ms between target disappearance and the reappearance of a spot. Second, the extent of the eye movement to this uncertain, poorly remembered target may not be properly registered. The combined influence of these factors produces only small errors in localisation, a finding that might be interpreted as evidence for a reliable extraretinal signal that specifies the extent of the saccade, but an analysis of eye movements made during the experiment suggests otherwise. The horizontal position of the eyes was monitored (with a resolution of ± 4 arc min) by measuring the amount of infrared light reflected from slit images that lay horizontally over the corneo-scleral boundary, and a continuous record of eye position, together with a record of target position, was made on an oscillograph.

These measurements, a sample of which is shown in Fig. 2, indicate that at the time the probe appears the eye has stopped

Fig. 2 Sample record of eye position during an experiment. The target stepped randomly 3.3° to the right or left and after 100 ms was extinguished. 500 ms later a probe appeared randomly at one of seven positions about the target point. The observer had to indicate whether the probe appeared to the right or left of the target. Corrective saccades occurred frequently after the probe appeared, usually so as to reduce an undershoot. Blank portions of the stimulus trace indicate that no spot was visible.

consistently short of the target by about 17 arc min, an amount close to that by which the target is mislocated. Moreover, the standard deviation of eye position (without allowance for error of measurement) is only a little greater (17 as opposed to 12.4 arc min) than that of judgements about target position.

Figure 3 shows that for steps in target position of 1.15° the mislocation is also close to the error in eye movement. Accurate measurement of eye movements to target steps of 6.6° was not possible, but errors in localisation follow the trend for smaller saccades.

Our results show that, following a saccade, the spot judged to lie in the target position is the one that falls on the fovea. Thus, to explain the small errors in locating targets after a saccade, we need only suppose that the observer relies on the eye movement being accurate and locates at the target position the spot that falls on the fovea. It is unnecessary to postulate an extraretinal signal that specifies accurately the size of the saccade; clearly,

Fig. 3 Accuracy and reliability of judgements about target location following saccades to target steps of different sizes (circles). Both parameters were estimated from probit regression lines. Points are averages for target steps to left and right, and a positive constant error indicates that the probe judged to lie on target was too close to the original fixation point. Accuracy and reliability of saccades to target steps of different sizes (squares). Points are averages for saccades to left and right. Open symbols, standard deviation; filled symbols, constant error.

some signal is needed to indicate that the eye has moved, but more precise information is not required.

Vanadate-stimulated natriuresis

THE observation^{1–3} that V(v) is a potent inhibitor of (Na⁺, K⁺)-activated renal ATPase raised the possibility that it has natriuretic and thus diuretic properties in the living animal. We report here experiments showing that it has.

Plastic catheters were placed in the urinary bladder and femoral vein of rats (250–350 g) under ether anaesthesia. While recovering from the anaesthetic, the animal was confined in a restraining box and placed on a laboratory balance. The opposite arm of the balance actuated the delivery of isotonic saline (145 mM NaCl, 5 mM KCl) from a peristaltic pump to the femoral vein, in such a way that, during the experiment, the urinary and evaporative losses were made good and the weight of the animal was maintained.

During the succeeding 2 h the rate of flow of urine became roughly constant. Sodium orthovanadate (1.5 µmol) was then injected intravenously in 0.15–0.3 ml of the same isotonic saline; these volumes are too small to affect urine flow by augmenting the plasma volume. Table 1, which summarises the results of four consecutive experiments, shows the total excretion of water, sodium and potassium during the hours immediately preceding and immediately following the administration of vanadate. The flow of urine increased dramatically within a few minutes of the vanadate injection, reaching peak rates of about 1 ml min⁻¹. As this represents approximately 50% of the glomerular filtration rate⁴, it is likely that vanadate acts, at least in part, on the proximal tubule. The sodium

Table 2 Distribution of ⁴⁸V 75 min after the intravenous injection of 1.5 µmol ⁴⁸V-vanadate

Tissue	Blood plasma	Renal cortex	Renal outer medulla	Renal papilla	Urine
⁴⁸ V content (µmol per kg wet weight)	14.9	62.0	10.2	7.8	2.6

concentration in the urine produced in response to vanadate approximated to that in plasma. The integrity of the nephrons was not lost, for neither glucose nor protein was detectable in any of the samples of urine. Also, the effect of vanadate seems to be reversible, as, in longer-term experiments, urine flow following a vanadate injection diminished after a few hours, but the kidney was still capable of responding to a further dose as it had before.

In the first of the experiments included in Table 1, we used ⁴⁸V-labelled vanadate and determined the distribution of tracer in the kidney and elsewhere 75 min after its administration, when the diuresis was still nearly maximal. Table 2 shows that ⁴⁸V was selectively concentrated in the renal cortex. Otherwise, the distribution of radioactivity in the various organs was similar to that described by Hathcock *et al.*⁵. Within 75 min of the ⁴⁸V injection, 43% of the radioactivity had been excreted.

We conclude that vanadate is a potent natriuretic and diuretic substance, perhaps the most potent now known. It remains to be determined (1) whether vanadate, at the naturally occurring blood or tissue levels, has a physiological role in controlling natriuresis, and (2) whether the natriuretic and diuretic effects of vanadate can be therapeutically useful.

4	2.10	0.220	0.197	28.5	3.91	0.301
Mean ± s.e.m.	2.57 ± 0.90	0.01 ± 0.099	0.299 ± 0.043	36.2 ± 5.1	4.84 ± 1.07	0.347 ± 0.032

The dose, 1.5 µmol, was chosen arbitrarily as that which, if it were distributed uniformly in the body water, would give a concentration sufficient *in vitro* to cause 75% inhibition of (Na⁺, K⁺)ATPase prepared from pig kidney. 1.5 µmol vanadate in a 300 g animal represents about 2.5% of the LD₅₀, determined in mice⁶; estimates of LD₁₀₀ suggest that vanadate is about equally toxic to rats and mice⁶.

* For comparison, it is worth noting that an equimolar dose of the therapeutic diuretic furosemide injected intravenously into a 300 g rat caused a diuresis averaging about 10 ml h⁻¹ during the first hour, with peak flow rates up to about 0.3 ml min⁻¹.

Peptidyl-transfer RNA hydrolase prevents inhibition of protein synthesis initiation

PEPTIDYL-tRNA HYDROLASE (called hydrolase below) catalyses the hydrolysis of peptides from peptidyl-tRNAs that are not bound to ribosomes^{1,2} but will not hydrolyse amino acyl-tRNA or fMet-tRNA_{fMet}. It is interesting that hydrolase seems to be ubiquitous in nature; it has been found in all cells where it has been sought, including yeast³, bacteria, rat liver and jackbeans⁴. However, the metabolic role of this enzyme has not been established. It is required for normal function, as a mutant strain of *Escherichia coli* with a temperature-sensitive hydrolase cannot continue protein synthesis at the nonpermissive temperature⁵. Hydrolase itself is not required for initiation, elongation or termination phases of protein synthesis⁶. Menninger⁷ has shown that peptidyl-tRNA, formed on ribosomes, accumulates at nonpermissive temperatures in cells with the temperature-sensitive hydrolase. Hydrolase thus seems to be a scavenger enzyme of peptidyl-tRNAs normally aborted from ribosomes during protein synthesis. Of interest now is why peptidyl-tRNA is frequently prematurely released from ribosomes and why protein synthesis is inhibited in the mutant strain with a defective hydrolase⁵. I report here work on the latter problem and present evidence which indicates that peptidyl-tRNAs accumulate and compete with *N*-formyl-Met tRNA_{fMet} during initiation of protein synthesis.

Two possible mechanisms of protein synthesis inhibition at 42°C in the temperature-sensitive hydrolase strain are that one or more infrequently occurring tRNAs may become sequestered as peptidyl-tRNA, resulting in inhibition of polypeptide elongation or, on the other hand, that the only known product of the reaction (peptidyl-tRNA) may interfere with initiation of polypeptides. Peptidyl-tRNA is not unlike *N*-formyl-Met-tRNA_{fMet}. Thus, these two similar compounds may compete at initiation for the P-site on the ribosome.

When the hydrolase mutant strain is incubated at temperatures intermediate between permissive growth and nonper-

missive growth (40, 40.5, 41 °C), partial inhibition of growth is observed. This is interpreted as limited inactivation of hydrolase, resulting in a reduced rate of peptidyl-tRNA hydrolysis. If elongation rates are affected at these intermediate temperatures, protein polymerisation time should be increased. If initiation of protein synthesis is inhibited, however, the polymerisation rate will remain unchanged for a specific protein.

The time lag between the induction of the lactose operon and the first appearance of β -galactosidase activity above basal enzyme level was used to estimate the peptide chain elongation rate^{8,9}. It has been shown that this approach is not a reflection of changed mRNA synthesis times⁸. Hence a measure of polymerisation time of β -galactosidase can differentiate between the two possibilities outlined above.

The data presented in Table 1 indicate that the rate of peptide-chain elongation does not change significantly with increase in growth temperature in the hydrolase temperature-sensitive strain. The chain elongation rate is slightly less in the mutant strain at 40 °C than in the parent strain (20%), but nearly identical at the permissive temperature (30 °C). However, the growth rate of the mutant strain decreases considerably as the growth temperature is increased from 37 to 41.5 °C, reflecting inhibition of protein synthesis by steadily increasing concentrations of peptidyl-tRNA in the cell. Furthermore, the relative rate of polypeptide chain initiation is proportionally decreased (Table 1, column 5). These data are derived from the initial slope of the induction curve; they reflect the relative number of molecules synthesised per unit time. The relative number of chain initiations in strain AA-7852 (*ptf*⁻) decreases by slightly more than half from 40 to 41.5 °C, and the doubling time decreases proportionally. No significant growth or β -galactosidase induction is observed at 42°C, reflecting complete inactivation of the hydrolase.

Other data suggesting that initiation of protein synthesis is inhibited in the hydrolase mutant strain at the nonpermissive temperature come from studies of the polysome distribution after shift to 43 °C. Menninger *et al.*⁶ found that polysomes slowly dissociated at 43 °C, forming 70S subunits. Elongation continues temporarily, resulting in dissociation of polysome structures. However, initiation only forms 70S units, possibly because of a peptidyl-tRNA in the P-site. This is consistent with the idea that some poison accumulates, very probably peptidyl-tRNA, but must reach a critical level before inhibition is seen. Protein synthesis is not inhibited in the hydrolase mutant until about 10 min after transfer to the nonpermissive temperature.

In conclusion these data show that the number of polypeptide chain initiations decreases as hydrolase is partly inactivated. On the other hand, the chain elongation rate is not affected. These findings imply that hydrolase plays an important part in cell metabolism by destroying spontaneously formed peptidyl-tRNAs which, in turn, inhibit protein synthesis initiation, probably by competing with *N*-formyl-Met-tRNA_{fMet} in the P-site of the ribosome.

This investigation was supported by the Iowa Agriculture and Home Economics Experiment Station and a grant from the NSF. I thank Mary Mascia for technical assistance.

	40.0 ± 0.05	110 ± 5	9.1 ± 0.2	75

Cells were grown in M-9 medium with 0.4% glycerol and required amino acids in a gyratory shaking water bath at the specified temperature⁶. Strains CP-78 (a K12 strain of *E. coli*, *arg*, *his*, *leu*, *thr*, *thi*) and AA-7852 (a single-step mutant of strain CP-78 that is now temperature-sensitive for peptidyl-tRNA hydrolase (ref. 5) were induced for β -galactosidase synthesis by addition of 5 mM 3', 5'-cyclic AMP and 1 mM isopropylthiogalactoside after growth at the specified temperature for 2 hours. The cultures were sampled every 5 s by taking 0.5 ml into test tubes containing 0.50 ml of a solution (1 mg ml⁻¹) of chloramphenicol in distilled water⁸. These samples were assayed for β -galactosidase activity by cell lysis with toluene and hydrolysis of o-nitrophenol- β -D-galactopyranoside (ONPG) at 25 °C. Polymerisation rate was established by the time required for the first newly synthesised β -galactosidase molecules to appear^{8,9}. There are 1,021 amino acids in β -galactosidase¹⁰. A change of 0.004 A₄₂₀ units equals 1 nmol of ONPG¹¹.

Inhibition of Q β RNA 70S ribosome initiation complex formation by an oligonucleotide complementary to the 3' terminal region of *E. coli* 16S ribosomal RNA

It has been proposed that a key event in the recognition of a prokaryotic protein initiation site by the ribosome is the interaction between the 3'-terminal sequence of the 16S rRNA and a purine-rich sequence preceding the initiator triplet by three to nine nucleotides^{1,2}. This hypothesis predicts that if the 3'-terminal region of the 16S rRNA were blocked, binding of the ribosome to the initiator region of an mRNA should be diminished or prevented, while binding to the trinucleotide A-U-G should not be affected. We have shown that the oligonucleotide A-G-A-G-G-A-G-G-U_{OH} (P-2a), eight bases of which are complementary to the sequence A-C-C-U-C-C-U-U-A_{OH} at the 3'-terminal region of 16S rRNA ($\Delta G = -16.9$ kcal mol⁻¹ calculated as described in Table 1), binds tightly to the 30S ribosome and is released as a complex with the 3'-terminal 49-mer of 16S rRNA after digestion with cloacin DF13 (ref. 3). We report here that this oligonucleotide either strongly inhibits Q β RNA binding to 70S ribosomes or

decreases the stability of the initiation complex formed in its presence. As we found that the formation of complexes of pA-U-G and 70S ribosomes was not inhibited by the oligonucleotide, we conclude that inhibition (or destabilisation) of Q β RNA binding is not due to an effect on the interaction between fMet-tRNA and the initiation triplet or on the association of the 30S and 50S ribosome subunits.

Incubation of the low-salt-washed ribosomes (which retain initiation factors) and intact Q β RNA in the presence of fMet-tRNA leads to the formation of a complex sedimenting at 70S (ref. 4). As in the case of all phage RNAs, ribosomes attach predominantly to the initiation site of the coat cistron, and to a lesser extent to that of the replicase cistron⁴⁻⁷.

Table 1 and Fig. 1 show the effect of preincubating ribosomes (5 pmol) with different amounts of purified P-2a before the addition of ³H-labelled Q β RNA (2 pmol). It is seen that the amount of Q β [³H]RNA in the 70S peak is about 0.4 pmol (20% of the input) in the absence of P-2a (Fig. 1, left figure) and decreases with increasing amounts of P-2a. At a molar ratio of P-2a to Q β RNA of 2.5, 50% inhibition of 70S complex formation was observed, and at a ratio of 10, inhibition was 87% (Fig. 1, right figure, Table 1). The effect of several other oligonucleotides on 70S complex formation was compared to that of P-2a in the experiment in Table 1. An equimolar mixture of P-2a and P-2b (which are difficult to separate) had the same inhibitory effect as pure P-2a.

To show that inhibition of complex formation was not due to an inhibitor other than an oligonucleotide, an aliquot of the mixture of (weakly ³²P-labelled) P-2a and P-2b was treated with Sepharose-linked RNase T₁; the equivalent of 20 pmol of the ³²P-labelled oligonucleotides, which after this treatment were completely digested (as shown by electrophoretic analysis) gave virtually no inhibition (Table 1). The RNase A-resistant oligonucleotides G-G-A-A-G-A-G-A-G-C_{OH} (P-4) and G-G-A-G-A-A-G-C_{OH} (P-6), which showed less complementarity with the 3'-terminal region of 16S rRNA (Table 1) than P-2a, were far weaker inhibitors; the concentrations required to give 50% inhibition were about three and five times greater, respectively,

Fig. 1 Effect of oligonucleotide P-2a on binding of Q β [³H]RNA to 70S ribosomes. The preparation of the pancreatic oligonucleotide P-2a will be described elsewhere³. Q β [³H]RNA, fMet-tRNA and ribosomes were prepared as described previously¹⁴. Low-salt-washed ribosomes (5 pmol) were incubated with or without P-2a (20 pmol) in 50 mM Tris-HCl (pH 7.5), 6 mM MgCl₂, 120 mM NH₄Cl, 0.5 mM GTP, 0.5 mM dithiothreitol and about 440 pmol of unfractionated, stripped tRNA charged with fMet (ref. 14) (estimated to contain 10 pmol of fMet-tRNA) in a volume of 10 μ l for 15 min at 37°C. Then, 2 pmol of Q β [³H]RNA (specific activity, 3×10^4 c.p.m. pmol⁻¹; in 2 μ l) were added to the reaction mixture and incubation was continued for 10 min at 37°C. 100 μ l of buffer B (10 mM Tris-HCl (pH 7.5), 10 mM MgCl₂, 50 mM NH₄Cl and 10 mM β -mercaptoethanol) were added and the sample was loaded on a 4 ml 10–30% sucrose gradient in buffer B. Centrifugation was for 90 min at 58,000 r.p.m. and 4°C in an SW60 Spinco rotor. 21 Fractions were collected on paper disks (Schleicher and Schuell, LS78 Ruffi, diameter 22 mm) and ³H radioactivity was determined in POPPOP-scintillator. The A₂₆₀ profile of a mixture of 30S, 50S and 70S ribosomes, run in the same conditions, was used to locate the ³H radioactivity sedimenting at 70S (indicated by a). The amount of 70S ³H radioactivity was calculated relative to the total ³H radioactivity recovered from the gradient (a + b). Left hand figure, without P-2a, right, with P-2a (20 pmol).

Fig. 2 Sedimentation analysis of complex formation between ribosomes and Q β [³H]RNA and [³²P]pA-U-G: effect of fMet-tRNA and oligonucleotide P-2(a+b). The reaction mixture contained 92 mM Tris-HCl (pH 7.5), 0.18 M NH₄Cl, 9.2 mM MgCl₂, 0.92 mM dithiothreitol, 0.92 mM GTP, 10 pmol of low-salt-washed ribosomes, oligonucleotide as indicated below and about 1.3 nmol of stripped, unfractionated tRNA loaded with fMet (estimated to contain about 30 pmol fMet-tRNA) in a volume of 13 μ l. After 15 min at 37°C, 2 pmol of Q β [³H]RNA (○) (specific activity, 1.3×10^5 c.p.m. pmol⁻¹) and 100 pmol of [³²P]pA-U-G (●) (specific activity, 1.9×10^4 c.p.m. pmol⁻¹) were added in 7 μ l and incubation was continued at 37°C for 10 min. The sample was then analysed essentially as described in Fig. 1. a, No oligonucleotide, plus fMet-tRNA; b, no oligonucleotide, no fMet-tRNA; c, 40 pmol of P-2(a+b), plus fMet-tRNA. Brackets indicate the fractions corresponding to the 70S complex.

Table 1 Inhibition of binding of 70S ribosomes to Q β RNA by oligonucleotides

Oligonucleotide	Nucleotide sequence (ΔG (kcal mol ⁻¹))*	Amount added (pmol oligonucleotide)	% of Q β [³ H]RNA bound to 70S ribosomes (relative to control†)	% Inhibition
None		none	100	0
P-2a (purified by ribosome binding) [‡]	A-G-A-G-G-A-G-G-U _{OH} (-16.9)	5	42.6	57.4
P-2a (purified by ribosome binding) [‡]		10	32.6	67.4
P-2a (purified by ribosome binding) [‡]		20	12.8	87.2
P-2(a+b) (1:1 mixture)	A-G-A-G-G-A-G-G-U _{OH} (a) (-16.9) G-G-G-A-G-A-A-G-U _{OH} (b) (-10.0)	20	8.8	91.2
P-2(a+b), treated with RNase T ₁ †		20	115.0	0
P-4	G-G-A-A-G-G-A-G-C _{OH} (-11.1)	20	43.4	56.6
P-6	G-G-A-G-A-A-G-C _{OH} (-7.9)	20	57.5	42.6
T-14	A-U-U-U-C-U-U-C-U-A-U-G _{OH} (-1.1)	20	105.0	0
T-2	A-U-A-U-U-A-U-U-U-A-C-C-G _{OH} (-1.1)	20	90.0	10.0

Low-salt-washed ribosomes (5 pmol) were incubated with oligonucleotides in the conditions described in the legend to Fig. 1 for 15 min at 37 °C, then Q β [³H]RNA (2 pmol, specific activity 6.9 $\times 10^4$ c.p.m. pmol⁻¹ or 3 $\times 10^4$ c.p.m. pmol⁻¹) was added to the mixture and incubation continued for 10 min at 37 °C. The mixture was diluted with 100 μ l of buffer B and analysed by 10–30% sucrose gradient centrifugation as described elsewhere⁵.

* Free energy of optimal interaction with the sequence HOA-U-U-C-C-U-C-C-A-C-U-A-G (5') of the 3' end of 16S rRNA was calculated according to Gralla and Crothers¹⁷, without considering the free energy contribution resulting from the bimolecular nature of the reaction.

† In the control experiment where oligonucleotide was omitted, about 20% of the input Q β [³H]RNA was bound to 70S ribosomes (see Fig. 1, a).

‡ BrCN-activated Sepharose 4B was prepared and RNase T₁ was immobilised essentially as described¹⁵. ³²P-labelled oligonucleotide P-2(a+b) (50 pmol in 5 μ l H₂O; specific activity, 200 c.p.m. pmol⁻¹) was allowed to run into a small column (0.1 ml) of immobilised RNase T₁ and to stand for 15 min at room temperature. The RNA was rinsed out of the column and an aliquot was taken for electrophoretic analysis¹⁶; only A-A-Gp, A-Gp, Gp and Up were detected. Digested RNA equivalent to 20 pmol of P-2(a+b) (as determined by radioactivity) was tested for inhibitory activity as described for the untreated fragments.

than those required with P-2a. Two pyrimidine-rich RNase T₁-resistant oligonucleotides, T-14 and T-22, gave virtually no inhibition at a molar ratio of 10 relative to Q β RNA (Table 1). It is interesting in this connection that AG-rich random copolymers were found to be potent inhibitors of ribosome binding to natural mRNA⁸.

To determine the dependence of pA-U-G binding to ribosomes on fMet-tRNA, a mixture of 5'-³²P-labelled pA-U-G (100 pmol) and Q β [³H]RNA (2 pmol) was incubated with ribosomes (10 pmol) in the presence or absence of fMet-tRNA and 70S complex formation monitored by sucrose gradient centrifugation. As shown in Fig. 2, the binding of Q β RNA as well as of the pA-U-G was strongly dependent on the addition of fMet-tRNA to the incubation mixture: 0.3 pmol of Q β RNA (15% of input) and 0.6 pmol of pA-U-G (0.6% of input) were bound when initiator tRNA was added, and 0.06 pmol were bound in either case when the tRNA was omitted. The binding of pA-U-G was almost proportional to its input level, up to 100 pmol. At 10 pmol, the binding of pA-U-G was 0.08 pmol, about one-quarter that of Q β RNA at an input of 2 pmol. These results may indicate a different rate of complex formation for Q β RNA and pA-U-G; it is less likely that the yield of 70S complex would reflect an equilibrium between free and complexed components in the conditions of our assay, as centrifugation through a sucrose density gradient removes the excess oligonucleotide from the equilibrium. Oligonucleotide P-2(a+b) (a mixture of P-2a and P-2b) inhibited binding of Q β RNA but distinctly stimulated that of pA-U-G (Fig. 2c, Fig. 3) at all levels tested; the values for 40 pmol of P-2(a+b) were 78% inhibition for Q β RNA and 42% stimulation for pA-U-G. The corresponding values for 40 pmol of oligonucleotide P-6 (see Table 1) were 21% and 25%, respectively. The stimulation of binding of pA-U-G by P-2(a+b) may be due to increased availability of ribosomes no longer bound to Q β RNA.

There are great differences in the stabilities calculated for the putative interactions between the 3'-terminal region of 16S

rRNA and the Shine-Dalgarno regions of different mRNAs². It has been proposed that both the Shine-Dalgarno interaction and the interaction between initiator site and fMet-tRNA anticodon have a role in the formation and/or stability of the initiation complex^{2,5} and that one or the other may make the greater contribution, depending on the nature of the mRNA. Several sets of experimental findings bear on this hypothesis. (1) In the case of the Q β coat cistron, where the Shine-Dalgarno interaction is relatively weak ($\Delta G = -7.9$ kcal mol⁻¹), a mutation converting the A-U-G initiator triplet to A-U-A reduces the amount of 70S complex recovered in binding experiments to less than 10% (ref. 5). An A-U-G $\rightarrow$ A-C-G mutation in the cistron for the 0.3 protein of phage T7 (ΔG of Shine-Dalgarno interaction = -10 kcal mol⁻¹) does not diminish the efficiency of ribosome binding (in this case, however, it is not excluded that binding might occur at an A-U-G triplet two codons downstream)⁹. (2) In the presence of fMet-tRNA, *Escherichia coli* ribosomes bind to the coat cistron and to a lesser extent to the replicase cistron, but in its absence only to non-initiator sites which show extensive complementarity to the 3'-terminal region of 16S rRNA ($\Delta G = -11.1$ to -16.9 kcal mol⁻¹). Ribosomes bind efficiently, even in the absence of fMet-tRNA, to an RNA fragment from the R17 initiator region of the A cistron, where the Shine-Dalgarno interaction has a ΔG of -15.8 kcal mol⁻¹ (refs 2, 10). (3) The trinucleotide pA-U-G binds to 70S ribosomes, and at least one mRNA, the λ Prm RNA, which carries the initiation triplet at its 5' end and thus lacks the 'Shine-Dalgarno' region, is translated *in vivo*¹¹; however, binding of the trinucleotide pA-U-G seems to be far weaker than binding of Q β RNA as judged by the molar amount of the material retained by ribosomes, and the efficiency of translation of the repressor gene by Prm promoter is an order of magnitude less than that of Pre, the same mRNA preceded by a leader sequence comprising a Shine-Dalgarno region¹². (4) A point mutation diminishing the extent of the Shine-Dalgarno interaction at the initiator region of the 0.3 protein of phage T7 causes a shift of

Fig. 3 Effect of oligonucleotide P-2(a+b) and P-6 on the binding of 70S ribosomes to Q β [^{3} H]RNA and [^{32} P]pA-U-G. Q β [^{3} H]RNA and [^{32} P]pA-U-G were incubated with ribosomes, fMet-tRNA and the amounts of P-2(a+b) or P-6 indicated, and 70S complex formation was determined as described in the legend to Fig. 2. $\circ$, Q β [^{3} H]RNA and P-2(a+b); $\bullet$, [^{32} P]pA-U-G and P-2(a+b); Δ , Q β [^{3} H]RNA and P-6; $\blacktriangle$, [^{32} P]pA-U-G and P-6.

ribosome binding to an A-U-G located 15 nucleotides downstream, whereas a suppressor mutation, which creates a more stable Shine-Dalgarno interaction at the original site, restores the normal ribosome binding capacity of the mRNA.

If P-2a blocks the formation of Shine-Dalgarno interactions, then ribosomes could only attach to Q β RNA by virtue of the interaction between fMet-tRNA and A-U-G. If we assume that there are no other important interactions between ribosomes and natural mRNA, the rate of formation or stability of complexes between 70S ribosomes and the trinucleotide A-U-G on the one hand and any other mRNA on the other should become similar in the presence of oligonucleotide P-2a. It will be of interest to compare the effect of this oligonucleotide on ribosome binding and protein initiation, both with Q β RNA and with other messengers.

An intervening sequence of the mouse β -globin major gene shares extensive homology only with β -globin genes

THE mouse β -globin major (β^{maj}) gene is interrupted by two intervening sequences of DNA that divide it into three discontinuous segments¹⁻³. The entire gene, including the coding, intervening and untranslated regions, is transcribed into a colinear 15S mRNA precursor⁴ containing a 5'-cap structure and 3'-poly(A) (refs 5-7). Because mature globin mRNA is significantly smaller (10S) and does not contain these intervening sequences, the 15S precursor must be processed. Such processing presumably accounts at least in part for the reduction in sequence length observed between so-called heterogeneous nuclear RNA (Hn RNA) and cytoplasmic RNA⁸⁻¹⁰. Intervening sequences seem to occur in a variety of genes and organisms^{1,11-18}, but their function and representation in the genome have been unknown.

The availability of cloned β -globin genes^{3,16} permits us to answer certain obvious questions about the structure and occurrence of intervening sequences. Previously, we examined the extent of the homology between cloned β -major and β -minor (β^{min}) genes by means of restriction endonuclease analysis and by visualisation of heteroduplex structures formed between them. Of the 7,000 base pairs compared, shared non-coding sequences comprised only a few hundred base pairs¹⁶. In the longer (646 base pairs) intervening sequence, homology was found only in the regions bordering the structural gene sequences; thus, the central portion of the intervening sequences has diverged. The significance of this conserved homology, perhaps representing retained regulatory signals or sites important for the elimination of intervening sequences, is unknown. Any homology to other portions of the genome has likewise been unknown. Do parts of the intervening sequence constitute a genetic signal retained among unrelated genes throughout the genome, analogous to bacterial insertion

Fig. 1 Derivation of intervening sequence containing probes from β^{maj} (M β G2) DNA. *a*, The M β G2 mouse genomic EcoRI fragment containing the β^{maj} gene, including flanking, transcribed but non-translated, intervening and coding sequences. This fragment was cloned intact into the plasmid PMB9, yielding PMB9· β G2 (ref. 2). *b*, (IVS-A), PMB9· β G2 DNA was digested with *Bam*HI and *Hind*III (New England Biolabs), ligated with similarly digested PBR322 DNA, and used to transform χ 1776 (ref. 2). Clones hybridising the excised 230-base pair fragment were picked, grown up, and the 230-base pair *Bam*-*Hind*III fragment cut out of a 9% polyacrylamide gel, eluted by electroelysis and concentrated on DEAE cellulose. *c*, (IVS-B), PMB9· β G2 DNA was digested with *Bam*HI and *Pst*I, and the appropriate 620-base pair fragment isolated from a 9% gel as above. *d*, (IVS-C), PMB9· β G2 DNA was cleaved with *Bam*HI and *Xba*I and the 1,500-base pair fragment isolated as above except from a 5% gel. $\square$, Genomic flanking sequences; $\blacksquare$, coding sequences; ▨ , intervening sequences; ▤ , transcribed, untranslated sequences.

Fig. 2 Hybridisation to genomic DNA of various probes containing intervening sequence from β^{maj} (MBG2). EtBr, an ethidium bromide-stained 1% Agarose gel containing 35 pooled fractions from an RPC-5 chromatograph of *Eco*RI DNA; direction of migration is from top to bottom. The DNA in gels identical to the stained gel shown was transferred to a Millipore nitrocellulose filter¹³ and hybridised to various ^{32}P -labelled probes (see Fig. 1) as follows: ^{32}P -pCR1 $\cdot$ βM9 (β -globin); ^{32}P -IVS-A; ^{32}P -IVS-B; ^{32}P -IVS-C; ^{32}P -pCR1 $\cdot$ αM10 (α -globin). Probes were labelled by nick-translation²² to specific activities of 86 c.p.m., 158, 12.7, 143 and 18 c.p.m. pg^{-1} , respectively.

sequences¹⁹? Are intervening sequences shared among genes expressed coordinately in synthetic pathways, such as those involved in erythropoiesis? Or are intervening sequences completely unique? To answer these questions, we have used an especially powerful form of analysis involving a two-dimensional distribution of *Eco*RI fragments of mouse genomic DNA, RPC-5 chromatography and Agarose gel electrophoresis. The resulting pattern is then transferred to nitrocellulose filters and hybridised *in situ* to ^{32}P -labelled probes²⁰ containing all or part of the β^{maj} intervening sequence. We have examined the

genomic representation of the larger intervening sequence of the mouse β^{maj} gene and report here that it shares extensive homology only with elements of the β^{maj} and β^{min} genes.

Figure 1 shows the original cloned mouse globin gene, β^{maj} (MBG2) (Fig. 1a) and the probes derived from it. The β^{maj} gene is comprised of genomic flanking, coding and intervening sequences, as shown. Preliminary sequencing studies (D.A.K., unpublished) indicate that the 5' terminus of the small intervening sequence begins after the codon for amino acid 30; its precise length has not yet been determined. The first probe, derived

from a sub-clone of M β G2, is a 230-base pair fragment which extends from a *Bam*HI site at amino acid codon 99 to a *Hind*III site near the middle of the intervening sequence; this probe (designated IVS-A) contains the most distal 18 base pairs of the 5' coding sequence and the proximal 220 base pairs of the intervening sequence. The second probe depicted in Fig. 1, a *Bam*HI to *Pst*I fragment of approximately 600 base pairs (designated IVS-B), also contains the distal 18 base pairs of the 5' coding sequence but extends through the intervening sequence to within 75 base pairs of the 3' coding sequence. The third probe, an approximately 1,500-base pair *Bam*HI to *Xba*I fragment (designated IVS-C) contains in addition to the distal 18 base pairs of the 5' coding sequence, the entire intervening sequence, 3' coding sequence, 3' transcribed but untranslated region, and approximately 600 base pairs of genomic flanking sequence.

To identify sequences in the mouse genome homologous to these probes, murine embryonic DNA was purified, fragmented with *Eco*RI and fractionated by RPC-5 column chromatography. Aliquots from the RPC-5 fractions were electrophoresed, blotted on to nitrocellulose paper and then annealed to a ³²P-labelled probe^{16,20}. The results of hybridisations with the three probes are shown in the third (IVS-A), fourth (IVS-B) and fifth (IVS-C) panels of Fig. 2. The identical appearance of these three panels is notable, as is their identity with the second panel (β -globin), where the probe was the ³²P-labelled β -globin structural gene sequence cloned in plasmid pCR1 (ref. 21). The two discrete bands observed with the β -globin structural sequence as probe (and hence, those bands in the same positions in the IVS-A, IVS-B and IVS-C hybridisations) represent the two non-allelic β -globin genes: the upper, less intense band is the 13-kilobase β^{maj} (M β G3); the lower, more intense band, the 7-kilobase β^{min} (M β G2). The last panel (α -globin) demonstrates the band pattern of mouse α -globin sequences; in this experiment, the probe was the ³²P-labelled α -globin structural gene sequence cloned in pCR1 (ref. 21). Note that three α -globin genes are detected and that there is no homology between any of these and the β^{min} probes (compare IVS-A, B and C to α -globin). The top panel (EtBr) does not depict an autoradiogram but is simply an example of a gel stained with ethidium bromide and photographed before blotting and hybridisation; note the large amounts of DNA of heterogeneous size in each RPC-5 fraction, each lane containing of the order of 10⁴ genomic fragments.

Before drawing conclusions from the above experiments, we should consider the ability of our probes to detect homologous sequences. From a comparison of the partial sequences of M β G2 (β^{min}) and M β G3 (β^{maj}) as well as heteroduplex studies, we are certain of at least 50 base pairs of homology between probes IVS-A or IVS-B and β^{min} (ref. 16; D.A.K., unpublished data); it is evident from Fig. 2 that this degree of hybridisation is detected. We know, however, from unrelated experiments, that IVS-A barely detects an 18-base pair homologous sequence (H.I.M., unpublished data). The minimum size of homologous sequences resolved in these experiments is, therefore, approximately 20–50 base pairs.

We conclude that the long intervening sequence of the mouse β^{maj} gene shares detectable homology in the mouse genome with only the β^{min} gene. We cannot rule out short sequences which might be more widely shared among intervening sequences and serve as recognition sites for processing. It is possible that rather than similarity or identity of primary sequence, there are within the intervening sequences characteristic conformations conferred on the mRNA precursors by secondary and tertiary structures. Alternatively, the sequences surrounding the intervening sequence may provide the specificity required for the elimination reaction. Such a possibility is especially suggested by what is known of yeast tRNA intervening sequences^{12,17}. These differ among tRNA precursors, whereas the conformations of the tRNA molecules themselves are probably quite similar. Further, recent evidence involving a portion of a putative intervening sequence in the chicken ovalbumin gene suggests that it is

present only in the ovalbumin gene¹⁸. Ultimately, a comparison of the structure of all these elements should permit us to define the critical features required for splicing.

Note added in proof: We have recently determined the entire nucleotide sequence of the mouse β -globin major gene (Konkel *et al.* *Cell*, in the press) and find short closely homologous sequences at the borders of both small and large intervening sequences.

Nature Index and Binders

The complete Index for 1977 is available, price £2.50 (UK), US\$5.00 (Rest of World). Copies of the 1976 Index are still on sale, prices as above

Binders for the journal are also available at £8.00 (UK), US\$16.00 (Rest of World) for three: a year of *Nature* fits into three binders

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, UK.

Errata

In the article 'The tau heavy lepton—a recently discovered elementary particle' by M. L. Perl, *Nature* 275, 273–278, in line 6 on page 274 for reaction (2) read reaction (3). In line 13 for equation (1) read equation (2).

In the letter 'Viral sequences related to a human skin papillomavirus in genital warts' by G. Orth *et al.*, *Nature* 275, 334–336, on page 335 right-hand column line 6 should read ... are close to those ...

The title to the letter by Jones, Kindman and Knowles, *Nature* 275, 564, should read: 'Stereochemistry of phosphoryl group transfer using a chiral [¹⁶O, ¹⁷O, ¹⁸O] phosphate monoester: the stereochemical course of alkaline phosphatase'.

matters arising

Possible Sun-weather correlation

GERETY ET AL.¹ recently repeated part of my work² on the correlation between solar activity and weather for the zones 50°N–60°N and 60°N–70°N. I was not surprised by the fact that the authors have found substantial differences between my results and theirs for the simple reason that the two statistical samples on which the papers were based differ significantly. In fact, in my work I have used only those stations which provided long-term observational data, whereas Gerety *et al.* used stations with observational data even of 1 or 2 yr. Furthermore, in my paper I excluded a few annual values of $R - R_0$ which appeared to differ significantly from the mean annual value. However, despite these remarkable differences between the two statistical samples, Gerety *et al.* have found a general similarity in the variation of the precipitation in the two northern zones. This can be clearly seen in Fig. 1 where the continuous lines represent my calculations and the dashed lines the calculations of Gerety *et al.* One could not expect to obtain a closer correlation from a comparison of two statistical samples so different in the kind and the number of stations used in the cited papers.

1. Gerety, E. J., Olson, R. H. & Roberts, W. D. *Nature* **272**, 231–232 (1978).
2. Xanthakis, J. *Solar Activity and a Global Survey of Precipitation* (Research Center for Astronomy, Academy of Athens, 1975).

GERETY REPLIES—Although in preliminary analyses stations with only a few years data were included, the study published in *Nature* included no stations with a length of record of < 15 yr. To be more specific about the statistical similarity between our separate samples: (1) In the latitude band 60°N to 70°N Xanthakis used 42 stations. Three of these stations had record lengths of less than 15 yr and two were located in another latitude band entirely. Our sample included all of those used by Xanthakis with the exception of the five just discussed and two more for which we could find no data. The total number of stations in our sample was 97. (2) In the latitude band 50°N to 60°N Xanthakis used 71 stations, one of which had a record length of less than 15 yr. Our sample included all but five of the remaining stations. The total number of stations in our sample was 159.

We agree with Xanthakis that there is a “general” similarity between his curves

Fig. 1 Comparison of the calculations of Gerety *et al.* (dashed line) and the author (continuous line).

and ours but fail to see any hint of correlation between our curves and solar activity as measured by Xanthakis' index Ia. Finally, if there were in fact a correlation between Ia and precipitation measured in this peculiar manner, it seems to us that it ought not to depend so strongly on one's choice of stations.

Oxygen in the palaeoaquatic environment

The article by B. and A. Henderson-Sellers has an inappropriate title because it is not concerned with oxygen in the palaeoaquatic environment *per se* but attempts to identify, at the end of the Precambrian, the most likely region on the Earth where diversification of multicellular animals took place, by examining oceanic oxygen levels from the average

position of the density gradient or pycnocline at that time. Thus they show pycnocline depth as a function of latitude, 600 Myr ago, on the basis of a model which depends on several assumptions, the principal being that the palaeocean was density-stratified like the water of a temperate lake during the summer², and from an assessment of the concentration of oxygen above the pycnocline (acting as a barrier to downwards diffusion of oxygen released by photosynthetic organisms) they conclude that multicellular animals originated, and diversified, in latitudinal zones between ~50 and 70° N and S. Their decision to examine the distribution of oceanic oxygen levels 600 Myr ago was evidently influenced by the very late and sudden diversification of life, that “apparently” took place at the end of the Precambrian.

Assuming that 600 Myr ago oxygen was limited to water above the pycnocline, the Henderson-Sellers have suggested only that, at that time, the surface waters of certain latitudinal zones contained a sufficiently high concentration of oxygen to be suitable for the existence of multicellular life. They have not provided evidence showing that such conditions did not exist at the same or different latitudes before 600 Myr ago and, therefore, have

failed to tie the origin and initial diversification of multicellular animals either to the end of the Precambrian, or to particular latitudinal zones. Evolutionary diversification must have been taking place at that time because once initiated, it is continuous. Eucaryotic unicellular organisms dependent on oxygen were living at least 300–400 Myr before the beginning of the Cambrian³, and the fully aerobic environment in which they existed⁴ was equally suitable for multicellular animals. That this was the situation for at least 100 Myr before the end of the Precambrian is shown by the presence of fossils of a variety of soft-bodied metazoans in late-Precambrian rocks in several parts of the world^{5,6}. These late-Precambrian organisms were, however, already complex forms, so that the evolution of metazoans from protists⁴ clearly took place still earlier in the Precambrian, and was not connected in any way with environmental conditions at the end of the Precambrian.

The concept of a sudden diversification of life at the end of the Precambrian derives from the time when it was widely believed (from the lack of fossil evidence) that metazoans evolved only shortly before the beginning of the Cambrian. Thus, Cambrian strata, in contrast to apparently unfossiliferous Precambrian rocks, were known to contain abundant fossils representing the principal animal phyla now inhabiting the world as well as extinct ones. The abundance of fossils at that time was a result of the acquisition of preservable hard parts independently by many groups of organisms. Although the latter was not synchronous, it seemed more nearly so when the Lower Cambrian was believed to represent a period of 30 Myr as against the currently recognised 50 Myr (ref. 7). The complex multicellular organisms that developed hard parts were, however, not living in the surface water of the ocean but on the sea floor, and so they were derived from less complex forms already adapted for a benthic existence. Hence, the sudden diversification of life attributed to the end of the Precambrian or to early Cambrian time refers only to the bottom-dwellers that acquired skeletons, as little is known about the variety of soft-bodied benthic and pelagic animals also living at that time.

Restriction of oxygen, before the beginning of the Cambrian, to surface or near surface water⁸ (above or within the pycnocline) or, in high concentration, to certain latitudinal zones, implies lack of disturbance of the density layers by currents like those of today which move water from one region to another or from one depth to another, and result in a mixing of water and distribution of oxygen to nearly all parts of the ocean. An ocean in which movement of water bodies was too slow to significantly affect the stratification would require a more uniform heat distribution than there is at present; such conditions

could only exist in the absence of continents (differential heating giving rise to complex wind patterns, movement of water bodies, and so on) or even of significant rises on the sea floor, that is, the ocean would have to have been global and of more or less uniform depth⁹. Emergence of continents took place long before the end of the Precambrian^{10,11}, and oceanic conditions would then have been comparable to those existing today. During the Lower Cambrian the world consisted of at least five continents separated by oceans^{12,13}, and in the latter, multicellular animals existed at both high and low latitudes¹². Colonisation of the sea floor and overlying waters took place more than 100 Myr before the beginning of the Cambrian as the oldest known metazoan faunas include both benthic and pelagic forms^{6,15}; some of them lived in shallow water whereas others inhabited relatively deep water⁶. Consequently, as far as the fossil record of Precambrian multicellular animals goes back, oxygen was present in water well below the level of the pycnocline.

If multicellular animals, from the time of their origin until 600 Myr ago, had been restricted to the surface water of certain latitudinal zones because oxygen was not available in sufficient concentration elsewhere in the ocean¹, either near the surface or below the level of the pycnocline, diversification would have been inhibited, as their migration (actively, or passively by currents) into other environments where they could survive and where adaptive evolution could take place would have been impossible.

B. AND A. HENDERSON-SELLERS
REPLY—Many of Anderson's points are outside the scope of our paper¹, as the temporal evolution from single- to multicellular life within the evolving ocean-atmosphere system is a wide topic and is discussed in more detail elsewhere². The choice of 600 Myr ago as an example of our model results² was intended to illuminate the discussions of evolutionary processes current in the literature. Many of his points are, of course, still widely contested. However, we attempt to answer the most obvious below. The question of oceanic stratification at our chosen period is still unresolved. Degens and Stoffers³ discuss the anoxic conditions at depth resulting from the chemistries associated with the two layers. Although the permanency of this stratification is in doubt, its certain occurrence lends credence to our model and provides at worst error bars on the timing. Hargraves⁴ postulation of a global sea, although recently criticised⁵, seems to be supported by more recent evidence and discussion^{6,7}.

The existence of a pycnocline, at least for long periods during the ocean's history, implies that the build up of oxygen in the upper layers did occur at times up to and including the diversification and emergence of land animals. Our article was intended to illustrate an additional and important factor in the total description of the complicated process of global evolution. The dynamic feedbacks between life, ocean and atmosphere during the evolution of the Earth will not be simply resolved.

Now available

A Review of Amino Acid Transport Processes in Animal Cells and Tissues

Joseph Lerner

The only comprehensive, detailed study of the current status of organ and tissue absorption of amino acids in a wide variety of organisms. Separate chapters are devoted to the latest developments in regulation and adaptation in transport processes, transport mechanisms, ion dependency of transport, sugar-amino acid interactions, transport during development, effects of hormones, cyclic nucleotides, starvation and dietary deficiencies on transport, osmotic function of amino acids, disorders of transport and the relationship between active transport of amino acids and their incorporation into protein. An invaluable and unique resource.

Contents:

Organ and Tissue Absorption of Amino Acids • Transport in Parasites • Transport in Marine Organisms • Ion Dependency of Transport • Ideas in Transport Mechanisms • Sugar-amino Acid Interactions • Regulation and Adaptation in Transport Processes • Transport During Development • Effects of Hormones and Cyclic Nucleotides on Transport • Effects of Starvation and Dietary Dependencies on Transport • Relationship Between Active Transport of Amino Acids and Their Incorporation into Protein • Osmotic Functions of Amino Acids • Amino Acid Transport and the Mechanism of Insulin Release • Miscellaneous Effectors of Transport • Disorders of Transport • Glossary of Transport and Associated Terminology • Kinetic Symbols • Suggested Reading List • References • Index

234 pages, glossary, index, 947 references

THE DRUGS HANDBOOK

Paul Turner and Glyn Volans

A dictionary of drugs, arranged in alphabetical order of their medically approved names, with a trade names index. Each entry gives a brief description of the actions, uses and adverse effects of each drug – the sort of information that has been almost unavailable in the non-specialist area of pharmacology until now. Moreover, the book is presented in a concise handbook format to fit easily into a briefcase or capacious pocket. It should prove invaluable to anyone involved in the medical use of drugs.

'Concise, accurate and up-to-date' – Miss W. E. Hector, Senior Lecturer, Queen Elizabeth College, London.

Novel Aspects of Reproductive Physiology

edited by C.H. Spilman and J.W. Wilks,
both of *The Upjohn Company*

The proceedings of the Seventh Brook Lodge Workshop on Problems of Reproductive Biology.

It has become strikingly apparent that the multiplicity of events in the reproductive process cannot be attributed solely to the gonadotropins or the gonadal steroids, nor can they be simply explained by the classical regulatory interrelationships of the hypothalamus and pituitary, or the gonad and its target organs. New biological activities have recently been observed in tissues and body fluids or their extracts; new chemical entities have been observed to appear in the reproductive tissues at discrete times or specific cellular sites; new interactions between tissues and cells of the reproductive organs have been proposed. The purpose of the Workshop was to focus on the current status of knowledge regarding several of these novel regulatory molecules and concepts, and to provide an impetus for further advances in these areas.

Newton's correspondence

I. Bernard Cohen

The Correspondence of Isaac Newton. Vol. VII: 1718–1727. Edited by A. Rupert Hall and Laura Tilling. Pp. 522. (Cambridge University Press: Cambridge and London, 1978.) £25.

WITH this seventh volume, the Royal Society's edition of the *Correspondence of Isaac Newton*, begun under the editorship of H. W. Turnbull (vols 1–3) and continued under J. F. Scott (vol. 4), is now brought to a conclusion. Volume 7 (like vols 5–6) has been edited by A. Rupert Hall and Laura Tilling. The editors observe that very few of the letters included here "may justly be described as scientific". There are exchanges with Varignon and Bernoulli about the calculus, but not its subject matter so much as a rehearsal of the old controversy with Leibniz of a decade earlier over questions of priority in invention. Similarly, an extended set of correspondence with Varignon concerning the *Opticks* deals not with Newton's experiments and theoretical explanations, but rather with the type fount, the details of printing, the illustrations, and so on. There are letters from Pemberton to Newton about the third edition of the *Principia* (1727), which Pemberton was seeing through the press. But Newton's replies are lost and, in any event, most of Pemberton's queries to Newton do not concern fundamentals of mathematics or of physics.

Perhaps the most interesting letters in this volume are those written by or to Pierre Varignon, then a professor of mathematics at the Collège Mazarin and an influential member of the Royal Academy of Sciences in Paris. Varignon was considered by both Leibniz and Johann Bernoulli to be a partisan of the Continental mathematicians, but he "maintained at least a superficial impartiality in the debate", and kept up a friendly contact with both Newton himself and Abraham De Moivre, one of Newton's chief spokesmen. Today's reader may still be astonished by both the heat of the debate and the degree of chicanery and plain dishonesty on the part of Newton, Leibniz, and practically everyone who was in any way associated with the issue. For example, Newton told Bernoulli that he had not "ever taken the trouble of spreading opinions

throughout the world"; when he had actually written the draft of the report of the Royal Society's committee to examine the question of the true discoverer or first inventor of the calculus. Nor was that all; on the publication of the committee's documentary report in favour of Newton, the *Commercium Epistolicum*, Newton wrote and published a lengthy (anonymous) summary or 'review' of it in English in the Royal Society's *Philosophical Transactions*. This was translated into Latin and published in a reprint of the *Commercium Epistolicum* with an additional preface (also anonymous) by Newton. As to Bernoulli, he said of a famous letter he had written (also published anonymously), "I am not certain of what kind that letter addressed to Mr Leibniz is of which you speak . . . I do not remember having written to him myself that day, yet I would not deny it altogether . . .".

On a different level altogether is a brief note to Fontenelle, in relation to the presentation to the Royal Academy of Sciences of the second Latin edition of the *Opticks* (1719). Referring to the novelties introduced in this edition, notably the additional Queries, Newton said that "Here I cultivate the experimental philosophy as that which is worthy to be called philosophy" and he added that in his treatise "I consider hypothetical philosophy not as knowledge but by means of queries".

The volume concludes with a discussion of Newton's genealogy and a lengthy appendix, containing additions and corrections to the first six volumes. A considerable part of these addenda deal with Newton's activities as Warden, then Master, of the Mint. It is thus seen that Newton's post "was clearly no sinecure". Not only did he have the difficult job of supervising the construction and operation of County Mints to "receive and recoin the old hammered money", but he took it on himself to attend to the interrogation and prosecution of counterfeiters. These new letters deal with the chronology of Newton's discoveries in the calculus, chemical experiments made by Boyle, and a draft of a proposition for the revised *Principia* (1713) dealing with the resistance experienced by a cylinder that moves through a fluid. In a letter of January 1675, Newton

thanks the Secretary of the Royal Society for the offer of remission of annual dues, explaining that he could no longer afford to remain a Fellow, as "the time draws near that I am to part with my Fellowship, & as my incomes contract." Newton evidently was to resign from his Fellowship at Trinity College in spring 1675, as he could not in conscience go into Orders, as was then required of all Fellows; in April 1675 the Lucasian Professorship—to which he was appointed—was exempted by Royal Patent from the rule about Orders, but for which Newton's professional career would have been severely interrupted.

Scientists and historians and philosophers of science will be grateful to A. Rupert Hall and Laura Tilling on having at last brought to completion the edition of Newton's correspondence, of which the first volume was published in 1959. But any users of this set will regret that the last volume does not contain a comprehensive index to the complete correspondence. Furthermore, the corrections and emendations at the end of vol. 7 apply to all previous volumes, but they neither incorporate the previous list of errata (at the end of vol. 3), nor do they refer the reader to the entries in the earlier list. Thus, every time a letter in vols 1–3 is consulted, the reader must look in two separate lists of errata, which is a great inconvenience. □

I. Bernard Cohen is Professor of the History of Science at Harvard University, Cambridge, Massachusetts.

Thin-layer chromatography

Practice of Thin-Layer Chromatography. By J. C. Touchstone and M. F. Dobbins. Pp. 381. (Wiley-Interscience: New York and Chichester, UK, 1978.) \$27.30; £14.50.

PAPER CHROMATOGRAPHY was taken up slowly and with some fear and trepidation by those brave enough to try it at all because neither the paper nor the solvents and reagents were suitable for the technique; and, indeed, it took some time for paper for chromatography to appear on the market. Conversely, thin layer chromatography

took off explosively because, by the time it appeared, most of the general problems of the technique had been solved and it was a relatively simple matter to transfer from paper to thin layers.

If you are about to start chromatography then this book will not describe how to separate the compounds of interest, be they aminoacids, steroids, dyes, and so on. However, if you have some or even a great deal of experience then it is a mine of information covering the whole subject in a most up-to-date manner. Extensive discussions on preparing plates, pre-coated plates, the mobile phase, types of chromatography, documentation, quantification and reproducibility, preparative and other aspects of the techniques are given in a very readable

manner. Many tricks of the trade are described and I found some which I had not picked up in over twenty years of experience. Conversely, I feel that I might add a few to their repertoire. The best way to cut foil-backed layers is with a guillotine and to prevent glass capillaries scratching plates it is best to place 1-2 mm plastic tubing over the end which will be applied to the plate.

This book can be confidently recommended to all who practise thin layer chromatography and it would be a valuable addition to all departmental libraries.

Ivor Smith

Ivor Smith is Reader in Biochemical Education at the Courtauld Institute, Middlesex Hospital, London, UK.

Animal communication

How Animals Communicate. Edited by T. A. Sebeok. Pp.1128. (Indiana University Press: Bloomington and London, 1978.) £40.

ABOUT ten years ago, T. A. Sebeok edited two books on animal communication, one of which became a standard reference work in the field. The present volume is intended to update and replace both of these earlier ones. Fitting two into one and taking account of progress has led to a massive volume at an astronomical price.

Editing a book to which there are 38 separate contributions must be a daunting task if the contributions are to appear on time and are to be well integrated with each other. Unfortunately, Sebeok has cut corners in these respects, the different chapters varying greatly in style, organisation, degree of detail and length, and many of them (presumably those by the more punctual authors) containing no references after 1974. Strictly imposed word limits tailored to the importance of each author's topic and more rigorous selection of the topics to be covered would have made a shorter, better and cheaper book. This is not to say that the book does not deserve some applause: many of the individual chapters will be, within their limited areas, the definitive reviews and works of reference which the whole book was intended to be.

One reason for its length is that the book is split into three sections, each classifying the field in a different way and thus involving some overlap. The variability of treatment is well illustrated by the first section, which deals with theoretical issues. Here there are three thorough and useful chapters on

evolution (Marler), ontogeny (Burgardt) and action patterns (Barlow). In the other three Lieberman repeats his controversial ideas on the evolution of language, Griffin gives a brief personal perspective and Robertson reviews cellular communication, a topic of little relevance to the book's main theme. The second section deals with communication split up according to the senses and is equally patchy. There are useful conventional reviews of pheromones (Shorey) and visual signals (Hailman), as well as two excellent ones on more specialist but intriguing phenomena: bioluminescence (Lloyd) and electric signalling (Hopkins). Beside these are a more or less irrelevant article on echolocation (Griffin), an out-of-date one on acoustics (Busnel),

reprinted from one of Sebeok's earlier books, and a chapter on tactile communication which deals only with humans (Geldard).

The third section of the book, which accounts for three-quarters of its length, covers communication in selected animal groups in a series of 25 chapters. Some of the groups about which less is known are dealt with almost species by species, yet a more restricted approach has had to be adopted to those which have been more widely studied. Hölldobler shows how well this can be done with his article on social hymenoptera, and the artiodactyls (Walther) and higher primates (Oppenheimer; Gautier and Gautier; Marler and Tenaza) also receive good thorough treatment. The birds lose out a bit with a relatively brief and general article by W. J. Smith. The book ends with an article by Sebeok on the relevance of animal communication to human studies, preceded by one on man-chimpanzee communication by Fouts and Rigby. The editor's view on the rather sterile controversy as to whether the feats of chimpanzees constitute language is neatly expressed by the appearance of the names of these chimps in what would otherwise be an author index.

Overall, this book contains much that is readable and interesting, but it falls short of being an encyclopaedic work of reference because it covers some areas very much more fully than others.

Interpreting fossil assemblages

The Ecology of Fossils: An Illustrated Guide. Edited by W. S. McKerrow. Pp.384. (Duckworth: London; MIT Press: Cambridge, Massachusetts, 1978.) £14; \$22.50.

THIS book is the first attempt to portray fossil communities of marine invertebrates from every geological system since the Precambrian. It contains 125 block-diagrams of fossil assemblages, each picturing animals and/or plants in life-position, in many cases their position when buried as fossils and their appearance in cross-section in the sediment. Each assemblage is described and for each system there is a general introduction. The book owes a great deal to Mrs. E. Winson for her excellent drawings. The fact that different taxa may be impossible to distinguish in these diagrams —

for example, *Orthambonites* and *Pleurorthis* in fig.5, or the two species of *Barillaria* in fig.115 — is a useful reminder to the student that fossils cannot usually be identified properly at a glance; but too many of the pictures are given impossibly accurate names.

Although biologists do not agree amongst themselves on how a community can be defined, the authors consider that there is only one way to define fossil communities: a group of animals living in the same habitat. This convenient empirical definition is elaborated in the introduction to the Silurian, and it becomes apparent that they recognise that it is the associations of taxa themselves that define both the habitat and the community living in it: habitat is not intended to be defined by the inorganic facies of the sediment. Nevertheless, many of the communities in this book are tied to particular facies environments — for example, "Upper Devonian Clastic Shelf" or "Muddy Lime Sand" (in the

Jurassic).

The authors recognise that the communities illustrated are a selection from the large number known and that the diagrams emphasise organisms that are common and easily preserved. The implication is still there that the assemblages illustrated are real associations of fossils. This is not always true, and it is noticeable that many of the "communities" are not tied to named stratigraphical units. Thus, fig.85, the Upper Jurassic "Calcarene Community", which from the presence of *Rhacella* can be presumed to be a Corallian assemblage, is unlike any single example of the 18 detailed benthic associations in the Corallian as described by Fürsich (*Palaeontology*, 20, 337-385; 1977). Similarly, the *Bostrychoceras* in fig.107 is unknown from the British Maastrichtian chalk "community", unfortunately here called the "Ostrea Lumata Chalk Community" after a species that is actually limited to a very small thickness of the succession that happens to lack many of the other fossils illustrated. These minor mistakes are only part of a general weakness, and perhaps inevitable limitation, of all the reconstructions: they are both unquantitative and subjective. Why include so few ammonites in the Jurassic where they are often abundant, and yet provide an illustration containing seven different species of ammonites in the Late Turoonian Hardground Community (fig.105), which in turn does not include or mention the much more common brachiopods? Why is a *Caninia* not illustrated in fig.50 when it is mentioned in the description of the community? Conversely, *Aviculopecten* is illustrated but we are told nothing of its ecology.

For a book on ecology, the actual amount of ecology given is often very limited, even allowing for the fact that many of the groups of organisms are extinct. For the Devonian, Permian, Triassic and Jurassic there are good attempts at an integrated interpretation of each community, but for many animals in other chapters nothing is given beyond whether it was benthic, planktic or nektonic. Quantitative information is scarce throughout. It is not explained that the linear scales to the diagrams are only to size the organisms, not to indicate the number of specimens that one can expect to find in the rock, nor their original abundance.

Although these weaknesses will be obvious to the professional, the book is likely to be welcomed by students. They will value the novelty of fossils being interpreted in assemblages that they might find for themselves, as opposed to a theoretical discussion of principles or a mere list of facts about

each phylum separately. Although mainly for the British reader, the associations are hardly tied to national frontiers. It would be equally useful elsewhere in northern Europe, and many of the Palaeozoic associations can be found in the eastern part of North America. Moreover, at least an outline is given in many chapters of modifications to be expected in North America and the Tethys. Future editions could be improved by the inclusion of a few famous foreign examples such as the Burgess Shale fauna and a rudist reef association; there could also be more examples of present-day communities, each with a fuller ecological synthesis. Most of all

the bibliography needs to be classified: at present it is no more than a list of the papers referred to. As a result there are three petrological papers by West, but on ecology only one each by Bromley, Fürsich and Kauffman and just two by Sellacher. No reference is made to work by Bulman, Carter, Bager, Hudson, Kirk, Nicol, Oliver, Sohl, Reid or Scott, just to mention some well known names who write in English. The only serious misprint is on p110 where none of the key letters to the diagram has been printed.

Communication update

On Human Communication: A Review, A Survey and a Criticism. Third edition. By C. Cherry. Pp.374. (MIT Press: Cambridge, Massachusetts, and London, 1978.) £12.25; \$21.85.

THE re-appearance of this book is both timely and welcome. Since the first edition was published the world has seen the emergence and explosive growth of information processing systems of all kinds — not only large-scale electronic computing machines, with associated developments in storage media, data-bases and information retrieval, but many others. Thus we have: satellite and ground-based microwave communication systems that have transformed the world into McLuhan's 'global village', allowing an estimated 0.7×10^9 people to view the late pope's funeral as it took place; new components for the optical transmission and manipulation of information, promising even greater speeds and data densities; private and commercial networks for linking many computers together; large on-line systems for airline reservations and hospital management; and, most recently, developments in component technology that have not only turned computers themselves into mere components, at component prices (so-called microprocessors), but have also allowed the economical production of a host of other 'intelligent' components that have revolutionised systems design in all areas of electronic information handling. Many such systems perform critical functions in society on the basis of information gathered by dialogue with people. By improving and disseminating knowledge of human communication we may hope to avoid such communication disasters as apparently occurred with the signal control system for Britain's M4 motorway in December

1976 when 11 people were killed or injured and the motorway was closed for over 6 hours.

The book is unchanged from the first edition, apart from the addition of one chapter and minor corrections. It is a tribute to the scope and fundamental nature of the book that it survives well this procrustean decision that would have proved fatal to books of lesser stature, but certain sections are consequently rather dated (for example, those touching on machine intelligence and perception, including the machine synthesis and recognition of human speech). Nearly all the shortcomings of the book arise from this source and from failure to update material prefaced by terms such as 'recent' and 'today'.

The book defines communication as an act of sharing, distinguishing sign systems of animals from human language, and symbols from words, noting that language is the basis of rational thought and conduct. It then traces the historical development of our current views on 'information', and goes on to examine and describe language. There is next a review of various methods of analysing speech; but by failing to treat modern developments the author omits mention of Linear Predictive Coding of the speech waveform as well as the Fast Fourier Transform, both of which are highly relevant to computer-based analyses of speech. Then the classical Wiener-Shannon statistical theory of communication is simply explained and the author goes on to show how Bar-Hillel extended notions of information measurement to the semantic domain, based on Carnap's theory of inductive probability. Chapter 7 reviews some of the basic facts and problems of human perception and cognitive activity, ending with the observation that it is the multitude of general concepts and powers of organising them by means of language that form the backbone of human communication, dis-

tinguishing humans from animals.

In the new chapter 8, explaining what is human about human communication, in the light of the recent interesting experiments on communication with apes, there is useful insight (for instance, the idea that classical stimulus-response psychology may be rejected as the sole basis for understanding humans, because such a restriction would rule out human communication and would fail to distinguish one's relationship to a person from one's relationship to a thing). The author also sets down an existentialist view of what it is to be human. However, in excluding computer 'languages' from the domain of true languages—and thus from human communication, preferring to call such constructs coding systems because they require no cognitive effort on the part of the machine — the author touches on an important point about human communication that is not followed up, despite being implied at numerous points throughout the book. The point is that we shall not truly understand human communication until we can understand what kind of cognitive effort is involved; until we can formalise just what changes occur in a receiver's world model, and know how to produce those changes most efficiently, or at least can state what kinds of signal strategies are most likely to be useful. A reference to work by Winograd, Winston, Charniak or Colby would seem relevant here.

The book is somewhat preoccupied with spoken and written symbolic forms of language, at the expense of graphical communication. It is still true that a picture is worth a thousand words, and some forms of dialogue are greatly facilitated by providing for much of the information to be communicated and manipulated in the graphical domain, as instanced by the work of Robert Spence, at Imperial College in London. Indeed, as far as communication between humans and machines is concerned, it is in this area that the greatest progress has been made, perhaps for the same reasons that pictures were used at an early stage in human-human communication. Pictorial representations can have just as rich a complex of syntactic, semantic and pragmatic rules, just as many paralinguistic features of various kinds, as written — if not spoken — forms of what is generally called language; but it seems probable that there is some fundamental difference in the way that picture or spatial reference information is handled by the human.

The general reader will undoubtedly wish to skip the mathematics, mainly in chapter 5, but will find the ground

has been carefully prepared for what follows at each stage of the developing argument. Great care has been taken with the choice of words and the form of expression, and the book is rich with insight and painstakingly collected background material. The historical references, the relevant asides, and the anecdotes are a pleasure and a real aid to understanding for all readers.

Pesticide ecology

Ecology of Pesticides. By A. W. A. Brown. Pp.525. (Wiley: New York and Chichester, UK, 1978.) £17.65.

THE title of this book seems highly relevant to the current interest in 'ecotoxicology'. The author is well-known and respected for his work on resistance of insects to insecticides, a topic that with its strong basis in genetics should lead easily into ecological considerations. In the event, I found the book a sad disappointment.

The first, introductory, chapter gives a brief outline of the main types of pesticide, the economic and medical reasons for their use, their potential hazards to man, and of resistance to insecticides. The bulk of the book, in thirteen chapters, takes insecticides, herbicides and fungicides in turn, and considers their effects on selected components of various habitats. For example, chapter 6 considers insecticides and fish, whereas chapter 8 considers insecticides and birds. This approach makes for a repetitive and superficial account of what could be unifying themes. Inhibition of cholinesterases by organophosphorus insecticides could provide one such theme. Instead, chapter 1 briefly states this as the mode of action, and chapters 6 and 8 give a few field observations on the degree of inhibition that is associated with death. There is little mention of the range of cholinesterases and acetylcholinesterases, and no mention of demyelination. There is no discussion of the possible implications for sublethal effects or of the difficulties in deducing from cholinesterase inhibition whether death is due to insecticide poisoning.

More important, there is a lack of ecology, which should surely mean a consideration of the interactions between pesticides and other factors, and their effects on population size and on community structure. Instead, a large part of these chapters consists of statements of the percentage reduction in population size for species exposed to pesticides in the field, of LD₅₀ and LC₅₀ values, and of residues found in

However, for the serious student of human communication, the book must be regarded as what it is in 1978 — only a beginning. Nevertheless, for pleasure or study, the book will prove a very sound investment.

David R. Hill

David R. Hill is Associate Professor of Computer Science at the University of Calgary, Canada.

tissues. The amount of data is overwhelming, and seems more suitable for reference than for reading. This may reflect the author's prefatory statement that the book metamorphosed from a concise text into a detailed review. The relevance of this material to the understanding of ecological events is difficult to see: when one deliberately kills members of one species changes in other species are bound to occur, irrespective of any direct effects that the pesticide may have on these other species.

At least one ecological principle is invoked, that maximum species diversity gives greatest stability to an ecosystem. This is accepted in chapter 2 without question and without supporting evidence, whereas there are many who would argue the opposite.

Chapters 9 and 10 are devoted to more general themes. The first considers organochlorine insecticides and eggshell thinning. The second considers the movement of insecticide residues, locally and globally. Food chains are considered in some detail, and are shown to concentrate persistent organochlorine insecticides. The account is, however, somewhat partial. Important conflicting evidence is not quoted, and other evidence is not critically appraised. Thus, in one example, concentrations of DDT in predatory fish and birds are given for visceral fat, whereas the concentrations in plankton and small fish are for whole bodies.

There is something of a North American bias in the material considered, with some notable omissions in references to the literature, and readers from other continents may wish that latin names had been given for all species, as well as their common names. These comments aside, the subject index lists both individual pesticides and individual species effectively, and the book could be useful for quick reference to some information on the acute toxicity of pesticides, their persistence and breakdown products.

Reading the isotopic clocks If you need age determination come to the experts

For the reliable data and custom service that your research demands, come to Teledyne Isotopes.

In 1955, we pioneered in age determination...and that pioneering spirit prevails today. We are the only commercial laboratory offering all major age determination techniques to the world wide geological community:

• C¹⁴ • Rb/Sr • Pb/Pb • K/Ar • U/Pb

Reliability of data is assured through:

- Sample analysis done in modern, efficient labs
- Inter-calibration with major university and government labs
- Use of N.B.S. standards and other internationally recognized reference materials

For all your age determination needs, contact the experienced company.

CAMAC—system design made easy

Not so many years ago oscilloscopes were being designed and built by research scientists for use in their own experiments. Today such a situation is rare. Oscilloscopes have become standard items that are commercially available but the need for complex electronics to collect data and control experiments has increased. Many research groups are once again facing the problem of designing and building complex data processing systems.

The use of small on-line computers is not a complete solution. A computer is often necessary to handle the volume and rate of data but it must still be connected to the experiment. To make progress in research an experimenter must acquire considerable expertise in computer science and electronics engineering. The problem first became acute in nuclear physics, and a standardised solution was sought. Big science could afford to provide professional support teams to design and build interface electronics and the expertise and experience of these teams have ensured that the solution is tailored to the needs of the research scientist.

The solution is called CAMAC. It has been commercially produced for some years now, it works and is available internationally at a reasonable price. More and more areas of research are turning to computer based systems and the existence of CAMAC ensures that the link between the computer and the experiment can be implemented painlessly.

The following three articles, written by recognised experts in the field, introduce the CAMAC system. They illustrate what CAMAC is, why it is used and how it is used. We hope that this introduction will remove many of the problems often associated with the use of small computers and will ensure that progress in research will be able to take full advantage of progress in electronics.

CAMAC specifications are now available as international and national standards. Further information and details of how to obtain documentation can be obtained from the following:

L. COSTRELL
National Bureau of Standards,
Washington, D.C. 20234

H. MEYER
ESONE/ECA Secretariat
Commission des Communautés Européennes,
CCR-BCMN, B-2440 Geel, Belgium

Introduction to the interface standards

Formally, the name 'CAMAC' denotes a set of standards for computer interface equipment. Informally it is applied to 'CAMAC equipment' which conforms to these standards and to 'CAMAC systems' assembled from this equipment. The CAMAC standards were originally developed to meet the needs of large-scale data acquisition systems for nuclear physics research. There have been other large-scale applications in computer control of processes and plant in industry and laboratories.

The following description of CAMAC is concerned mainly with the important but less spectacular field of application to small or medium computer systems for automated control and data-acquisition in a wide variety of laboratories. On-line systems involve connections between the computer and various control and measuring devices. These may use analogue signals (voltage, frequency, time, pulse-rate, and so on) or digital signals. The connection to the computer must use the particular input-output interface standard adopted by the computer manufacturer. CAMAC offers a powerful and flexible means of matching the differing standards of the computer and the external devices.

The basic principle of CAMAC (Fig. 1) is an assembly of plug-in modular units, one of which is connected to the computer and the others to various external devices and signals. The units are linked by a multi-wire highway (the CAMAC Dataway) which is an integral part of the chassis housing the plug-ins. Each plug-in occupies a multiple of 1/25th of the width of the chassis (Fig. 2), and generally has front-panel connections to external devices and signals, and rear connections to the Dataway highway. The Dataway carries signals for digital data and for control of data transfers, and also distributes power. The specification defines the mechanical dimensions of the plug-ins and their interface to the highway in just

sufficient detail to ensure that any plug-in will fit into the chassis and communicate by the highway. It leaves complete freedom to design plug-ins with a wide variety of facilities and external interfaces, and to use appropriate materials, components and styling. A typical highway operation takes 1 μ s to address a plug-in module and transfer to or from the computer a data word containing up to 24 bits. This is faster than the sustained data rate of most computers, but slow enough to be technically conservative.

The symmetrical name 'CAMAC' was chosen to symbolise this assembly of plug-ins facing in one direction to the computer and the other to the external devices. The name is now usually assumed to stand for 'computer automated measurement and control', which is a good indication of the main areas of application.

The CAMAC standards were developed by an international group representing users' interests in developing and applying laboratory instrumentation systems. The main standards¹⁻³ and other subsidiary standards were published by the Commission of the European

Communities, and were also published in identical form in the US. They are now being re-issued by the International Electrotechnical Commission and by various national standards organisations.

CAMAC is a standard that encourages manufacturers to produce compatible products which can then be assembled into systems by or for the users. It has led to the commercial production of over 1,000 plug-ins, together with supporting products such as the chassis, by 29 firms in many countries, often with the assistance and involvement of major users.

The main strength of CAMAC lies in the many hundreds of different types of plug-ins that face outwards to the external devices and signals. The functional characteristics and external interfaces of these plug-ins are determined by the users' needs and by market forces, rather than by the CAMAC specification. They range from quite simple units in one module of width through to highly complex units that may occupy two or more modules of width and may include a micro-processor. Some indication of the rich variety of these units can be seen from the following examples:

- General purpose units to accept or deliver digital signals, typically following CAMAC recommended practice for front-panel interfaces based on TTL circuit technology, and so suitable for use with the majority of modern items of equipment.

- Units to accept or deliver specialised signals, such as peak-sensing analogue-to-digital converters for the nuclear field.

- Units that are instruments in their own right, such as digital voltmeters in CAMAC units.

- Units that communicate with external instruments, for example through parallel digital interfaces or the General Purpose Instrument Bus.

- Units that are connected by communication links to peripherals such as teletypes or VDUs, or to a host computer.

Fig. 1 Basic small CAMAC system

Although each of these plug-ins is associated with a particular class of external device or signal it can be used with any computer. The basic costs of the mechanical parts and Dataway interface can be shared by several repeats of the same function within the same plug-in. Thus there are single-width CAMAC plug-ins containing, for example, 12 counters, 16 analogue-to-digital converters, or 8 digital-to-analogue converters.

A wide choice of plug-ins is also available for connecting CAMAC to the computer. Here four different strategies have been adopted, to cover varying requirements for the system configuration: (1) in small stand-alone systems the CAMAC plug-in can include a micro-processor; (2) in small systems with a separate computer, the CAMAC plug-in has an external interface to match the I/O standards of a particular computer (Fig. 1). This arrangement is widely used, and plug-ins are available to match most popular minicomputers; (3) in larger compact systems not exposed to electrical interference the plug-in can be connected to the computer by a CAMAC parallel highway (Fig. 3). This can serve seven CAMAC assemblies, and there are units to couple it to many popular computers; (4) in larger dispersed systems that are exposed to interference the plug-in can be connected to the computer by a CAMAC serial highway (Fig. 3), which can serve 62 CAMAC assemblies.

Although some of these units couple CAMAC to one specific type of computer they can be used with any of the plug-ins that interface to external devices and signals. In typical configurations of CAMAC systems (Figs 1 and 3) all the internal interfaces conform to CAMAC standards, and many of the external interfaces follow CAMAC recommendations.

With falling costs of computers and memory, the computer program specific to a particular application has become a major part of the system cost, especially in 'one off' systems. In any on-line system the software must control input-output through the interface. In the case of CAMAC all I/O operations are controlled by unified commands which specify the plug-in module, a subsection of the plug-in (such as one of the 12 counters, 16 ADCs or 8 DACs

Fig. 3 Larger CAMAC system. See Fig. 1 for key to interface standards.

mentioned above) and the type of operation (such as reading to the computer or writing from the computer). As these commands are uniform for all plug-ins from all manufacturers this helps to simplify and rationalise the software. Several different recommendations for CAMAC I/O software have been published and implemented, to take advantage of the varying needs and skills of the users. First there are recommendations⁴ for macro-instructions for systems programmed in assembly language, an approach often adopted by larger users with appropriate staff. Then there are recommendations for sub-routines⁵, typically to take advantage of the FORTRAN programming experience of scientists. Third, there is an extended form of BASIC⁶ which requires little previous experience of programming or CAMAC. Another derivative of BASIC is well established in the UK for testing CAMAC equipment and for small-scale systems. These four well-documented approaches to CAMAC software provide overlapping coverage of a wide range of situations.

As a multi-national standard that is not tied to any particular firm or type of computer CAMAC has the advantage of a multiplicity of

suppliers, so that the availability of equipment for replacements and extensions is not subject to the commercial policy or survival of any one firm. The wide range of commercially available equipment makes it possible to assemble systems with the minimum of hardware development. At one extreme, the most frequently needed equipment is usually available from several competing suppliers. At the other extreme, equipment to meet some specialised requirement can often be found by searching the published worldwide guide of CAMAC products⁷. Software products are readily available, but generally on an informal or semi-commercial basis from large user organisations.

CAMAC is not a standard that impedes progress—it deliberately allows freedom to exploit new technology such as improved integrated circuits and microprocessors, and to provide the facilities and configurations needed by the user. CAMAC is seen to have considerable advantages in flexibility, versatility, generality and availability when compared with other established methods of interfacing, such as computer manufacturers' interface equipment, specially designed equipment, and the General Purpose Instrument Bus used on many instruments.

A worked example of system design

Using the CAMAC standards as a basis for laboratory system design, provides practical benefits for the scientist who requires real-time computing power in his research. This can be illustrated by working through the design and implementation of a specific example.

The particular requirement concerned a data acquisition system for a gamma camera, for a large hospital in Belgium. The primary function of the system was to interface to the camera which produces two analogue pulses that have to be amplitude analysed, and the resulting data transferred to a host processor 150 m away. The processor's task was to generate full colour graphic displays of the collected data, and the design of the acquisition system permitted dynamic studies of the camera output to be made with far better time resolution than previously possible. The overall system now gives the doctors not only an improved diagnostic capability on existing camera measurements, but also provides new diagnostic performance on dynamic studies, at the same time generating very significant savings in operating costs over the present photographic methods of recording camera data.

The acquisition system plays only a small, albeit crucial, role in the overall system. It must therefore not only meet the specific

DATA PROCESSING — CONTROL — NUCLEAR — MEDICAL INDUSTRIAL — COMPUTER INTERFACING

HYTEC ELECTRONICS are specialists in CAMAC INSTRUMENTATION. We offer a wide range of Camac Modules, Computer Interfacing and System Generation. We can supply Computer Pices and Operating Systems to suit your requirements, Standard or Special Modules.

Camac Modules include: LSI-11 Interfaces, 12-13-16 Bit DACs, Pulse Generators, HP21 Interfaces, Scalers, Word Generators, LSI-11 Computers, Pre-set Counting Registers, Video Display Drivers, Floppy Disc Interfaces/Systems and Data Stores, Input/Output Registers, 16-32 Multiplexers, 12-13 Bit ADCs.

To aid system completion and installation, we are generally able to supply other manufacturers' Hardware and Software, whether Camac or otherwise. We combine our range of standard modules with a free consultancy service, which helps you gain access to the Camac World. This service is backed up by our ability to design and build special modules and systems to your exact requirements.

Operations Systems and Software include RT11, RSX11, Fortran, Basic RT Basic, Caty, Forth, Coral and Macro. In short you name your problem in instrumentation/control and we will gladly tell you how Camac and Hytec can help. Please contact either Richard Tatham or Dave Pym.

VIDEO DATA ACQUISITION in CAMAC

The **MODULAR VIDEO SYSTEM APPROACH** implemented in the International CAMAC Standard permits LeCroy's new Series 8258 Video Digitizing System to offer conveniently-expandable memory and instant interfacing to a variety of readout devices, and flexible signal conditioning and display options.

The 8258 System digitizes at rates up to 20 MHz with 256 level resolution. Data is stored in 128K memory modules and can be **READ OUT** via CAMAC at rates up to 1 MHz/Word or **DISPLAYED** through an 8 MHz external port.

Superior digitizer fidelity (30 MHz bandwidth, 25 psec aperture jitter) permits the extraction of accurate information about high frequency signal components.

For details and other questions, contact LeCroy/California or your local LeCroy Sales Office.

30 MHz analog bandwidth makes the 8258 especially useful for CCD CAMERAS as well as Vidicon inputs.

LKB Ampholine® PAGplate.

Ready-made for electrofocusing of 48 samples in under 3 hours.

Your time and samples are too valuable to lose with home-made gels for analytical electrofocusing. Use Ampholine PAGplates instead.

Ampholine PAGplates bring you both convenience and speed. We make them under controlled conditions so that you get excellent reproducible separations of your valuable samples in every run.

Use each PAGplate whole for analyzing up to 48 samples simultaneously under identical conditions, or, for fewer samples, cut off the amount you need and store the rest until the next run.

Ampholine PAGplates come in four pH ranges: 3.5 to 9.5 (LKB catalog no. 1804-101); 4.0 to 6.5 (1804-102); 5.5 to 8.5 (1804-103); 4.0 to 5.0 (1804-104). After use, fix and stain your PAGplates, dry them, and store for future reference.

LKB offers the complete system for electrofocusing: Multiphor, LKB 2103 Power Supply, Ampholine® and Ampholine® PAGplates — your standards in electrofocusing. All supported by LKB Application Notes and *Acta Ampholinæ* Literature Reference List.

For more information write to LKB: the only complete source of experience, knowledge and equipment for electrofocusing.

Fig. 1 Block diagram of gamma camera data acquisition system.

performance objectives, but must also be easy to use, maintain and develop as new requirements emerge, whilst minimising costs and implementation time scales at all times.

The starting point in the design of a system to meet this requirement was to base it on CAMAC equipment. In this specific case the decision proved to be readily justifiable, as the system was implemented almost entirely from standard CAMAC products. This was not possible with any other interface scheme. One other approach often considered is the design and construction of a special purpose system. Such an approach raises many fundamental questions of system structure, such as the size of the basic module, the power supply requirements, the way in which each unit relates to the others and so on, none of which have direct relevance to implementing the actual system, but all of which can have a vital impact on the ease with which the system is commissioned, used and maintained, and its flexibility in

copling with new requirements. CAMAC provides a rigorously defined system framework within which the designer is free to concentrate on solving the specific problems posed by the requirements, whilst at the same time building in flexibility into the basic design process. The special design approach was in fact ruled out by the hospital, as they neither had, nor wanted, the level of electronic expertise required to implement a custom-built system. The block diagram of the system is shown in Fig. 1, and divides naturally into three parts; the camera interface, the computer interface, and the link between the two. The requirements for connecting to the camera were very particular to both the specific model of camera used, and the types of measurements required from the system. However, most of this unique requirement was met by a combination of currently available CAMAC units. The special unit acts mainly as a mechanical interface for the cabling between the other units. It contains

only about 20 integrated circuits that control the interconnections in the manner required to achieve the overall interface function. Note that units made by four different companies are used. The system designer is not restricted by the competence of any one supplier. Indeed it is not unusual to find one CAMAC supplier with special competence in analogue unit design, whilst another specialises in the rather different, but equally complex discipline of computer interfaces to CAMAC. Total control of the camera interface is through the CAMAC Dataway, and so it can in principle be controlled by any CAMAC Dataway controller, from a microprocessor resident in the same assembly, to any of the system configurations the CAMAC standards have defined.

The computer interface requirements for this system were more complex than for many laboratory systems. In addition to the normal programmed I/O to control the data acquisition, data transfers have to be at high speed, directly into the host computer's store, and in either List mode (one word at a time transferred into successive memory locations) or in Spectrum mode (the data word is used to address a memory location, whose contents are automatically incremented). Even so the system could be constructed entirely from available CAMAC units, and needed no special design effort. The benefit can be more readily appreciated by the realisation that the unit design effort embodied in just this part of the system represents several man-years of work. Finally the standard CAMAC parallel highway, extended by readily available extender units, was used to provide the required high-speed link over the 150 m between the computer and the camera. For the majority of the units selected in the whole design, the system designer had a choice of several different suppliers. For example, the Crate Controller could have been obtained from at least 10 other companies. Neither would the system design have been significantly affected had the host processor been one of a very substantial range of other types, as most of the system is independent of the computer type, and suitable computer interfaces to the CAMAC parallel highway are available for many different models of computer. That it was possible to meet this somewhat unusual system requirement using available CAMAC units, is a good indication of the scope and range of CAMAC products that are now available to the system designer.

The 'acid test' of any system structure is the ease, or otherwise, with which individual elements designed to be compatible with the system can in practice be combined into a working system. Experience over the past eight years has shown the CAMAC standards to be soundly based, with the integration of individual units into a working system remarkably free of those 'unexpected' interactions that can often affect less completely specified structures. In the case of the camera application this was demonstrated by the ease with which the various manufacturers' units were incorporated. System commissioning was also greatly assisted by the availability of system test and diagnostic equipment, and particularly by the availability of system test software for most of the individual units. The only special test software required was a set of short programs to establish that the system performed the overall functions correctly. All of the diagnostic and test software is written in a high-level BASIC-like language, enabling the user to take advantage of these packages for system maintenance.

The lack of these support facilities can extend commissioning and fault-finding times very significantly.

As a direct consequence of employing commercially available products, the documentation on the individual units is usually to a high standard. The system designer is left with the relatively straightforward task of describing the interaction between these items, and the overall system functions. Good documentation, however, is essential if a system is to remain serviceable in the medium term. It is not uncommon to find equipment that has had to be scrapped once the originator was no longer available to maintain it, because the documentation was never produced. Of course, problems in system design do not end with the commissioning of the system, even assuming that it does fully meet the user's requirements. The system has to be kept in service, and so ease of maintenance can be an important system design consideration. Certainly this was true of the camera system, and the CAMAC approach addresses this problem in several ways. For example, the structure is modular along functional lines. This simplifies the isolation of a fault to a particular unit, and allows first-line maintenance by unit replacement. The system-test software and hardware mentioned above also simplify this process. Faulty units can usually be returned to the supplier for rectification, thus taking advantage of their sophisticated automatic test equipment. As CAMAC equipment is often sold as individual products to system builders, items are often available either 'off the shelf' or on short delivery, and this can act as a valuable back-up to the normal system spares.

Initial system design often makes little or no allowance for the further development of the system. With the CAMAC approach the flexibility to cope with the needs for expansion and up-grading is built into the system structure. Since the initial camera system was commissioned, several additional requirements have been considered, that illustrate this point. The first is to connect the system to three other cameras over the next year or so. As the computer interface will support up to 49 CAMAC chassis, there is in practical terms no physical limit to the number of cameras that could be connected. The second is possibly more interesting, in that it demonstrates how the CAMAC standards have managed to evolve and anticipate new system requirements. As more cameras are added, the host processor will not be able to cope with the instantaneous data rates being generated, and the intention is to add local processing to each camera interface to preprocess the data. The most recent CAMAC standard covers exactly this requirement, and microcomputers are already available that will go into the camera interface assembly and provide the required function.

One final benefit that came from the use of CAMAC in this system was the genuine assistance the hospital staff were able to get from the CAMAC user community in Belgium, in terms of providing basic training and familiarity with CAMAC.

I thank Professor C. Beckers and M. Steels of the Department of Nuclear Medicine, of the Hospital UCL-St Luc, for presenting this interesting problem for us to solve and the directors of GEC-Elliott Process Automation Limited for permission to publish this article.

CAMAC applications in biological systems

The application of CAMAC to biology has been given an impetus in recent years by the increasing use of large scale experimental facilities producing neutron or photon probes. Data rates may be high and to make the best use of these facilities it becomes of paramount importance that experiments should be highly automated.

From the point of view of such laboratories CAMAC provides a very good solution to several requirements. The systems must be flexible as they may be required to adjust to new experiments every few days so that the hardware must clearly be modular. It must also be largely available commercially because, though there will always be special units that must be designed 'in-house', the total quantity of units required will usually exceed the local design and production capacity of the laboratory. Maintenance problems are simplified as is software implementation as the use of a standard forms a well understood bridge between the programmer or maintenance engineer and the application.

These are general points that apply to systems outside biology as well as within it. Furthermore, though they may seem to be less pressing, these considerations arise also for the individual experimenter implementing a system at his home laboratory.

Several laboratories are using CAMAC to support experiments in biology. At the high flux neutron reactor of the Institut Laue Langevin (ILL) at Grenoble CAMAC output registers are in use for positioning stepper and servo motors on diffractometers and monochromators. Small Angle Scattering (SAS) cameras at ILL use incrementing CAMAC memories to interface 2-D detectors with up to 128×128 cells.

The European Molecular Biology Laboratory (EMBL) is standardising the use of CAMAC and it is in use at the main centre at Heidelberg and their outstations at the electron synchrotron DESY at Hamburg and the ILL. Among its present and planned uses are for experiments on fly flight dynamics, EXAFS (extended X-ray absorption fine structure) experiments, centrifuges, stepper motors and polar coordinate X-ray detectors. Three film scanners are interfaced by CAMAC to two Nord-10 computers and a PDP-11/45 and two film writers to Nord-10s. At the DESY outstation the CAMAC serial highway is used to connect two experimental areas separated by some 300 m.

On the electron synchrotron NINA (now closed) at Daresbury, monochromators were also positioned by CAMAC stepper motor drivers and monitored by shaft encoders. Incremental encoders were interfaced by CAMAC up-down binary counters and absolute encoders by input registers. CAMAC 24-bit pre-set scalars were used to record data from ion chambers on EXAFS experiments. An electron storage ring, known as the SRS, is being constructed at Daresbury as a dedicated source of synchrotron radiation, and it is due to become operational in Spring 1980. The data acquisition system will use CAMAC (as does the control system). Among the instruments planned for the SRS are multiple solid-state

detectors. They are being made for energy-dispersive SAS experiments and high rates ($100\text{K counts s}^{-1}$) are desired from each detector. It is intended that incrementing CAMAC memory be used for the data accumulation.

The MRC (Medical Research Council) at Cambridge is developing an experiment using CAMAC to study the dynamic response of muscle to a stimulus. The magnitude of intensity peaks on a linear position sensitive detector will be studied over the 200 ms or so duration of a twitch with the aid of 100 buffered scalars. The scalar buffer registers will be read out every millisecond into a 32K word CAMAC memory while counting proceeds. To achieve the required high rate of transfers on the CAMAC dataway a simple auxiliary crate controller will be used to transfer data from the scalars to the memory.

We hope that these few examples have shown that the same units, stepper motor drivers, memories and scalars, for instance, are relevant to several different experiments. Note too that in CAMAC these units are computer independent it is apparent that an experimenter wishing to set up a new instrument or experiment will find that most if not all of the interfacing problems are already solved. As more systems are implemented in CAMAC the number of shareable and transportable solutions to problems in experimental biology will continue to grow. Daresbury intends to encourage this by loaning CAMAC systems to prospective users of the SRS. They may then develop instruments and experiments in advance of bringing them to the SRS and establish systems at their home laboratories which are compatible with those at the SRS.

To complement the ease with which CAMAC systems may be configured it is highly desirable to provide software that may be as easily written. CAMAC assists here too as the use of standard hardware promotes standard hardware-handling facilities in the software. Several different approaches to this have been adopted. At Daresbury a version of BASIC has been developed with extensions to drive CAMAC efficiently. This will make it possible for the biologist himself to write the programs to control his experiment. The extended BASIC compiler, called CATY, is also in use at EMBL, DESY enabling the two laboratories to share programs. This has happened in the case of EXAFS experiments even though different computers are in use.

As CAMAC finds application in the major facilities, techniques and equipment will evolve that match the many new applications in the area of biological science. This will lead to the availability of equipment that will be relevant also to the small biology laboratory and the scientist will be able to take advantage of the application of computing and modular electronics. This should enable scientists to use data acquisition and experiment control systems employing mini and micro computers in the study of biology without having to devote a significant proportion of their time to problems of electronics.

We thank Drs P. N. Clout of EMBL, R. Ghosh of ILL and A. R. Faruqi of the MRC, Cambridge for providing information used here.

(Published for the International Institute for Applied Systems Analysis, Oxford, etc.: Pergamon Press, 1978.) £15.

THE WOLFSON GEOCHEMICAL ATLAS OF ENGLAND AND WALES, initiated and compiled by the Applied Geochemistry Research Group, Imperial College of Science and Technology, London, England. Direction: John S. Webb. Pp. 69 + 1 + 2 transparent overlays, folio, paper covers. ISBN-0-19-891113-0. (Clarendon Press/Oxford University Press, 1978.) £35.00.

WOLF, Helmut. *Ausgangspunktung II Aufgaben und Beispiele zur Praktischen Anwendung*. Pp. xiv + 353. ISBN-3-427-7836-8. (Dummlerbuch 7836.) (Bonn: Ferd. Dummler Verlag, 1979.) DM 48.

Technology

A GENERAL INTRODUCTION TO FRACTURE MECHANICS (A Journal of Strain Analysis Monograph). Pp. ix + 178. ISBN-0-85298-383-2. (London: Mechanical Engineering Publications Ltd., 1978.) £7.

BRYERS, Richard W. (editor). *Ash Deposits and Corrosion due to Impurities in Combustion Gases*. Proceedings of the International Conference held at New England College, Henniker, New Hampshire, June 26-July 1, 1977. Co-sponsored by The American Society of Mechanical Engineers, Electric Power Research Institute, and US Department of Energy. Pp. xii + 691. ISBN-0-89116-074-4. (Washington and London: Hemisphere Publishing Corporation in association with McGraw-Hill International Book Co., 1978.) \$44.50.

ELECTRIC VEHICLE DEVELOPMENT GROUP. *International Conference on The Economic Use of Electric Road Vehicles in a Changing Environment*. Sheffield, 23-24 May 1978. Pp. 102, paperback, A4. ISBN-0-906048-08-7. (Hitchin, Herts.: Peter Peregrinus Ltd., Conference Publication 15, 1978.) £11.50 in UK, £13.50 overseas, excluding North America.

FEDA, Jaroslav. *Stress in Subsoil and Methods of Final Settlement Calculation*. (Developments in Geotechnical Engineering, 18.) Pp. 215. ISBN-0-444-99800-4. (Amsterdam, Oxford, New York: Elsevier Scientific Publishing Co., 1978.) Dfl. 80, \$34.75.

HOOGENDOORN, C. J. and AFGAN, N. H. (edited by). *Energy Conservation in Heating, Cooling, and Ventilating Buildings: Heat and Mass Transfer Techniques and Alternatives*. Lectures and papers presented at a seminar sponsored by the International Centre for Heat and Mass Transfer, held at Dubrovnik, Yugoslavia, Aug. 29-Sept. 2, 1977. (Series in Thermal and Fluid Engineering, 2) volumes. Pp. xii + 901. ISBN-0-89116-094-9 (Vol. 1), 0-89116-095-7 (Vol. 2). (Washington and London: Hemisphere Publishing Corporation, 1978.) \$79.50 for set of 2 vols.

HOBSON, G. S. *Charge-Transfer Devices*. Pp. xvi + 207. ISBN-0-7131-3396-1. (London: Edward Arnold, 1978.) £14.

IVES, Kenneth J. (edited by). *The Scientific Basis of Flocculation*. Proceedings of the NATO Advanced Study Institute, Christ's College, Cambridge, U.K., July 3-15, 1977. (NATO Advanced Study Institute Series: Series E: Applied Science, No. 27.) Pp. vi + 369. ISBN-90-286-0758-7. (Alphen aan den Rijn, The Netherlands: Sijthoff and Noordhoff, 1978.) Dfl. 72; £33.50.

MCCALL, James L. and FRENCH, P. M. (edited by). *Metallography in Failure Analysis: Proceedings of a Symposium sponsored by the American Society for Metals and the International Metallographic Society, held in Houston, Texas, July 17-18, 1977*. Pp. vii + 301. ISBN-0-306-40012-X. (New York and London: Plenum Press, 1978.) \$42.

O'CALLAGHAN, P. W. *Building for Energy Conservation*. Pp. xvi + 232. ISBN-0-08-022120-3. (Oxford, etc.: Pergamon Press, 1978.) £10.

PADDAY, J. F. (edited by). *Wetting, Spreading and Adhesion: Comprising papers (with discussions) presented to a Symposium, organised by the Colloid and Surface Chemistry Group of the Society of Chemical Industry, held on 27-29 September 1976 at Loughborough University, Leicestershire*. Pp. xiv + 498. ISBN-0-12-544350-1. (London, etc.: Academic Press, 1978.) \$33.00.

POMEROY, C. D. (edited by). *Creep of Engineering Materials* (a Journal of Strain Analysis Monograph). Pp. x + 238. ISBN-0-85298-352-2. (London: Mechanical Engineering Publications Ltd., 1978.) £7.

SACHS, Peter. *Wind Forces in Engineering*. Second edition. Pp. x + 400. ISBN-0-08-021299-9. (Oxford, etc.: Pergamon Press, 1978.) £20.

YEMURI, V. *Modeling of Complex Systems: An Introduction*. (Operations Research and Industrial Engineering Series) Pp. xvi + 448. ISBN-0-12-716350-9. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$19.50.

AWARDS

The Columbia University's 1978 Louisa Gross Horwitz Prize has been awarded to **David H. Hubel** and **Torsten N. Wiesel** (Harvard University), and **Vernon B. Mountcastle** (The Johns Hopkins University), who will share the award (\$25,000) equally for their contributions to our understanding of the brain.

The Institute of Food Science and Technology has awarded the Mounfield Prizes to **S. R. Tomlinson** (National College of Food Technology) and **Dut Fan Chung** (Polytechnic of the South Bank).

A limited number of Research Fund grants, each of £200, will be awarded by the Chemical Society for the year 1979. Application forms, together with the regulations governing the Fund, may be obtained from Dr Malcolm D. Robinson, The Chemical Society, Burlington House, London W1, UK. The closing date for applications is 1 November 1978.

The Fifth Marconi International Fellowship Award will be given to a person who has made outstanding advances in satellite and space technologies relevant to improving world communications, according to Walter Orr Roberts, Fellowship Secretary. Nominations should be submitted before 15 November, 1978, to the Marconi International Fellowship, Aspen Institute, 1919 14th Street, No. 811, Boulder, Colorado 80302.

MEETINGS

4 December, **Prospects for Power from Ocean Waves**, Edinburgh (Executive Secretary, The Royal Society of Edinburgh, 22 & 24 George Street, Edinburgh, UK).

5 December, **Vibrational Spectroscopy in Inorganic Chemistry**, London (Stanley Langer, The Chemical Society, Burlington House, Piccadilly, London W1, UK).

6-7 December, **The Evolution of Adaptation by Natural Selection**, London (Executive Secretary, The Royal Society, 6 Carlton Terrace, London SW1, UK).

9 December, **Tay Estuary Symposium**, Dundee (Dr J. McManus, Department of Geology, The University, Dundee, UK).

12-13 December, **The Middle Atmosphere as observed from Balloons, Rockets and Satellites**, London (Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1, UK).

9-11 April 1978, **Metal Ion Transport and Storage**, Sheffield (Professor P. M. Harrison, Department of Biochemistry, University of Sheffield, Sheffield, Yorks, UK).

17-21 April, **Special FEBS Meeting on Enzymes**, Dubrovnik (Secretariat: Laboratory of Biochemistry, Technological Faculty, Pierottijeva, 6/V1, YU-41000 Zagreb, Yugoslavia).

20-21 April, **Recent Advances in the Study of British Flora**, Manchester (Miss L. Shore, Department of Botany, The University, Manchester, UK).

28 April-2 May, **81st Meeting of the American Ceramic Society**, Cincinnati (R. L. Berger, 3211 Civil Engineering Building, University of Illinois, Urbana, Illinois 61801).

7-9 May, **The Role of Peptides in Neuronal Function**, Bethesda (Dr Barker, Building 36, Room 2C02, NIH, 9000 Rockville Pike, Bethesda, Maryland 20014).

20-21 June, **New Horizons in Industrial Microbiology**, London (Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1, UK).

27-31 August, **The Role of Water in Urban Ecology**, Amsterdam (K. C. Plaxton, PO Box 330, Amsterdam, The Netherlands).

2-7 September, **7th International Meeting of the International Society for Neurochemistry**, Jerusalem (Marco Trabucchi, Ente Universitario Lombardia Orientale, Istituto di Farmacologia e Terapia, Via Valsabbina, 19, 25100 Brescia, Italy).

3-5 September, **Erosion by Liquid and Solid Impact**, Cambridge (5th International Conference on Erosion by Liquid and Solid Impact, Cavendish Laboratory, Madingley Road, Cambridge, UK).

3-6 September, **EMAG 79**, Sussex (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

3-7 September, **Insect Neurobiology and Pesticide Action**, York (The Society of Chemical Industry, 14 Belgrave Square, London SW1, UK).

5-9 September, **15th International Congress of Therapeutics**, Brussels (Secretariat of the Congress, Department of Cardiology, Hopital Universitaire Saint-Pierre, rue Haute 322, 1000 Brussels, Belgium).

10-13 September, **1st International Symposium on Neuroactive drugs in Endocrinology**, Milan (Eugenio E. Muller, Department of Pharmacology, University of Milan, 32 Via Vanvitelli, 20129 Milan, Italy).

12-13 September, **How will tomorrow's microprocessor based process instrumentation communicate?** London (Miss Audrey Mills, Sira Institute Ltd, South Hill, Chislehurst, Kent, UK).

16-21 September, **4th Conference on Photographic Gelatin**, Oxford (H. A. Adam, Processing Technology Laboratory, Kodak Ltd, Headstone Drive, Harrow, Middlesex, UK).

17-20 September, **2nd International Reindeer/Caribou Symposium**, Røros (E. Reimers, Institute of Zoophysiology, University of Oslo, Box 1051 Blindern, Oslo 3, Norway).

17-21 September, **7th International Congress of Pathology**, Valencia (Professor A. Lombart-Bosch, Department of Pathology, Medica School, Valencia Apartado 2045, Spain).

19-21 September, **4th National Quantum Electronics Conference**, Edinburgh (Dr B. S. Wherrett, Physics Department, Heriot-Watt University, Edinburgh, UK).

25-27 September, **Organisation of Macromolecules in the Condensed Phase**, Cambridge (Mrs Y. A. Fish, Faraday Division, The Chemical Society, Burlington House, London W1, UK).

The previous list of meetings was in *Nature* of 19 October, page 679.

UNIVERSITY OF RHODESIA DEPARTMENT OF CROP SCIENCE

Applications are invited for the post of
**SENIOR LECTURER/
LECTURER IN PLANT
BREEDING AND GENETICS**

Preference will be given to applicants with relevant postgraduate qualifications and experience. The appointee will be required to undertake research in the breeding of more productive crops in such crop species as groundnuts, sweet potatoes and other food crops which are cultivated mainly by peasant farmers and farmers in a developing agricultural sector. The appointee will be required to assist with teaching in Genetics and Plant Breeding courses in the B.Sc. Agriculture with honours degree and assist in the supervision of research students reading for higher degrees. This post will be funded for an initial period of three years. It is hoped that the successful applicant will take up the appointment in March 1979.

Salary Scales (approx. stg. equiv.): Senior Lecturer, £7,544 by 292 to £8,423 by 310 to £9,973; Lecturer Grade I, £6,843 by 257 to £7,871; Lecturer Grade II, £4,224 by 222 to £5,334 by 257 to £6,619.

Applications: (6 copies) giving full personal particulars (including full names, place and date of birth, etc.), qualifications, experience and publications and names and addresses of three referees should be submitted by 15 January 1979, to the Registrar, University of Rhodesia, P.O. Box P 167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained.

Overseas applicants should send a full copy of their applications to the Association of Commonwealth Universities (Appis), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233 4143) or our nearest British Consular Office. 8182(A)

THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S HOSPITAL

DEPARTMENT OF EXPERIMENTAL PATHOLOGY

Research Assistant required to work on basic research into inflammation and rheumatology for a two year period, with a possibility of working towards a higher degree. Salary Scale £3,384 to £4,882 plus £450 London allowance. Further particulars may be obtained from Professor D. A. Illingworth. Applications should be sent to The Secretary, The Medical College of St Bartholomew's Hospital, East Smithfield, London EC1A 7BE. Closing reference 806 8091(A)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

Applications are invited for the post of
LECTURER

in the PHYSIOLOGY DEPARTMENT from January 1, 1979 or as soon after as possible. Salary on scale £3,909 to £7,754 plus £450 London Allowance. Further particulars from the Secretary of the School, 8 Hunter Street, London WC1N 1BP, to whom applications (six copies, including names of two referees) should be sent not later than November 18, 1978. 8129(A)

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF CHEMISTRY

Applications are invited as soon as possible for an S.R.C. Postdoctoral Fellow to study the kinetics and mechanisms of the reactions of electronic defects ("colour centres") in simple ionic solids such as alkali halides, using the technique of pulse radiolysis. The project is a continuation of on-going research in this area being supervised by Drs G. W. A. Newton and V. J. Robinson. Research experience in the solid state or in pulse radiolysis would be an advantage. Initial salary not less than £3,883 p.a. Superannuable. The post is for one year in the first instance with the possibility of renewal for a further year. Applications, including a curriculum vitae and the names of two referees should be sent to Dr V. J. Robinson, Chemistry Department, The University, Manchester M13 9PL (from whom further details may be obtained). 8130(A)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF FORESTRY RESEARCH ASSISTANT IN FOREST ECOLOGY

Applications are invited for the above post. The successful applicant will work on a project to devise options for managing parts of certain native pinewoods of Scotland such that they may be conserved as important natural ecosystems yet yield sustained amounts of timber. The sponsor is Nature Conservancy Council. Qualifications: degree in Forestry, Biology, Ecology, Botany or Zoology. Principal investigator: Professor J. D. Matthews.

Salary on scale 1B £3,384 to £4,882 per annum. Duration 21 months from November 1978.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by November 17, 1978. 8108(A)

ANGLO-AUSTRALIAN OBSERVATORY RESEARCH ASTRONOMERS

The Anglo-Australian Observatory comprises the 3.9 metre telescope near Coonabarabran, N.S.W. and a laboratory at Epping near Sydney, Australia. There is a scientific staff of 6 astronomers, 3 of whom are nominated by Australia and 3 by the U.K. The 3 Australian and 1 of the U.K. positions become vacant between 1 July, 1979 and 1 January, 1980.

Candidates should have strong backgrounds in some branch of Physics or Astrophysics, including theory. Appointments will be fixed terms of 1 to 5 years, with salaries in the range \$A14,829 to \$A29,356 per year (Subject to review in 1979) plus other allowances, fares etc.

Applications should include:

1. Age, citizenship, country of residence and marital status.
2. Qualifications and experience, including date of Ph.D.
3. Astronomical research projects for which telescope time will be sought (sufficient information is required to show that the proposals would be competitive in applications to the panel for the allocation of telescope time).
4. Any instrument development project in which the applicant is particularly interested.
5. When applicant would be available.
6. Length of appointment envisaged.
7. Names and addresses of three referees.

Applicants should arrange for the three references to be sent directly to the Secretary by the closing date of 5th January, 1979.

Applications should reach the Secretary, Anglo-Australian Telescope Board at either Department of Science, P.O. Box 449, Woden, A.C.T. 2606, Australia or Science Research Council, P.O. Box 18, Swindon SN2 1ET, United Kingdom. 8142(A)

SHEFFIELD SOUTHERN HEALTH DISTRICT (TEACHING)

DEPARTMENT OF BACTERIOLOGY

A vacancy exists in the Group Department of Bacteriology situated at the Royal Infirmary, The Jessop Hospital for Women and Hallamshire Hospital for—

A NON-MEDICAL BACTERIOLOGIST

Basic Grade or Probationer

Applicants should possess a 1st or 2nd class Honours Degree in Biological Sciences and should have spent part, preferably the major part, of their course in Microbiology.

Whitley Council Conditions of Service apply.

Salary Scale: £3,486 to £4,275 per annum for new entrants to the Health Service.

Visits welcomed, by appointment with Mr J. M. Hindmarch, Principal Non-Medical Bacteriologist, Royal Infirmary, Sheffield S6 3DA (Telephone 0742-20977, ext. 326).

Applications stating age, qualifications and experience naming 2 referees to the District Personnel Officer, District Personnel Office, Floor 'B', Hallamshire Hospital, Glossop Road, Sheffield S10 2JF. 8179(A)

CHANGE OF ADDRESS

The Advertisement offices for NATURE have moved to
3 DYERS BUILDINGS, LONDON, EC1N 2NR
TELEPHONE: 01 831-6901

Australian Telecommunications Commission Materials Analyst (\$A19,657-20,867*)

Telecom Australia invites applications from men and women for appointment to the above position in its Research Department located at Headquarters in Clayton, Melbourne, Victoria.

The successful applicant will be required to plan, supervise and participate in advanced chemical research and investigation into materials and develop methods for their application within Telecom Australia. The duties include development and application of complex analytical equipment and advanced methodology utilising Scanning Electron Microscopy (SEM), Secondary Ion Mass Spectrometry (SIMS), emission absorption and thermal analysis.

Qualifications

A tertiary degree or diploma in an appropriate physical science together with extensive research and administrative experience and leadership ability.

Conditions of Employment

will be similar to those in the Australian Public Service.

*At present rate of exchange £1=\$A1.70.

Interviews

It is anticipated that a senior Scientist of Telecom, Australia will be in London on or about 27/28 November to interview suitable applicants.

Please send a full curriculum vitae together with day-time telephone number on which you can be contacted to: Recruitment Officer, Public Service Board, Australia House, Strand, London WC2B 4LA to arrive by the 10th November.

8176(A)

LINCOLN COLLEGE

New Zealand

CHAIR IN ENTOMOLOGY (Agricultural Zoology)

The Council of Lincoln College, University College of Agriculture, invites applications for the Chair in Entomology, resulting from the impending retirement of Professor R. A. Harrison.

Applicants should hold an advanced degree in Science or Agricultural Science and have an established record of research and/or teaching in some branch of agricultural zoology.

The successful applicant will be appointed as Head of Department and will be responsible to the College Principal for the administration of his Department.

The appointment will be made within the existing range of professorial salaries, NZ\$23,012 to NZ\$29,188 per annum, the commencing salary being determined by the College Council.

Expenses of appointment reimbursed up to specified limits. New Zealand Government Superannuation is available.

Further details and general Conditions of Appointment are obtainable from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on January 15, 1979 8089(A)

UNIVERSITY OF SURREY RESEARCH OFFICER— CARBON FIBRES DEPARTMENT OF METALLURGY AND MATERIALS TECHNOLOGY

A post has become vacant in our Fibres and Composite Materials Research Group for work on an investigation of the surface characterisation of high modulus carbon fibres.

The principal method of investigation will be, thermal desorption of surface active groups and their qualitative identification and estimation by mass spectrometry. The work will be supervised by Dr W. Watt, F.R.S., and carried out in collaboration with Materials Department, Royal Aircraft Establishment.

The post will be suitable for a graduate physical chemist or physicist with interests in surfaces and solid state.

Preference will be given to candidates with a lively interest in practical work and an imaginative approach to interpretation.

The appointment will be for one year. Starting date is visualised as November 1, 1978 or as soon as possible thereafter. Salary will be on an appropriate point on the Research and Analogous Staff Scales Range £3,384 to £4,882 per annum.

Applications in the form of a curriculum vitae, including the names and addresses of two referees should be addressed to Professor J. E. Bailey, Department of Metallurgy and Materials Technology, University of Surrey, Guildford, Surrey GU2 5XH 8113(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the following posts in the
SCHOOL OF MINES

- (a) CHIEF TECHNICIAN
IN METALLURGY DEPARTMENT
- (b) CHIEF TECHNICIAN
IN MINING ENGINEERING
DEPARTMENT

Higher National Certificate, plus considerable experience in workshops or laboratories associated with Metallurgy and/or Mineral Dressing. For post (b), applicants should have considerable experience in workshops or laboratories with Mining (Drilling Machines, rock mechanics and ventilation laboratories, drawing ability). Duties include supervision of laboratories, setting up and maintaining equipment.

Salary scale, K5,316 to K6,324 per annum (£1 sterling equals K1.57). The British Government may supplement salaries by £3,606 per annum (Sterling) for married appointees and £1,620 per annum (Sterling) for single appointees (reviewed annually and normally, free of all tax) and provide children's education allowances and holiday visit passages, family passages, superannuation and medical aid schemes; regular overseas leave, various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent direct to Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia by November 22, 1978. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 8154(A)

UNIVERSITY OF CAPE TOWN SENIOR LECTURER/ LECTURER IN BIOCHEMISTRY

Applications are invited for a post, vacant from February 1979. Appointment, according to qualifications and experience, will be made on the salary scale—Senior Lecturer R8,460 by 360 to 9,900 by 450 11,250 per annum, or Lecturer, R6,3 by 360 to 9,810 per annum. In both cases, the salary will be supplemented by a pensionable allowance of 15.5%.

Candidates with a strong interest and experience in the following field will receive preference: structural chemistry of proteins and/or protein-nucleic acid interaction, structure as function of chromosome protein-hormone-receptor interaction.

Applicants should submit curriculum vitae, stating present salary, research interests and publications when available. If appointed, and names and addresses of three referees. The post may also be filled on a contract basis for 2 to 3 years with the possibility of renewal or conversion into a permanent post. Applicants should state whether they wish to be considered for contract appointment or a permanent post.

Memoranda concerning the position and general conditions of service should be obtained from the Registrar, Room 10, University of Cape Town, Private Bag, Rondebosch, C.P. 7700, by whom applications must be received not later than November 30, 1978 8090(A)

UNIVERSITY OF GUELPH College of Biological Science DEPARTMENT OF NUTRITION

Applications are invited for a position of Assistant Professor Nutrition. Candidates should be training in experimental nutrition nutritional biochemistry. The successful applicant will participate in teaching the metabolic aspects of nutrition at the undergraduate and graduate levels, and will develop a research program on some aspect of the nutrition evaluation of food. Curriculum vitae and names of three referees should be sent to Dr H. S. Bayley, Chairman of Search Committee, Department of Nutrition, College of Biological Science, University of Guelph, Ontario Canada N1G 2W1 by January 1, 1979. Appointment is subject to final budgetary approval 8092(A)

UNIVERSITY OF GUELPH College of Biological Science DEPARTMENT OF NUTRITION

Applications are invited for a contractually limited position of Assistant Professor in Nutrition (2 year term). Candidates should have training in experimental nutrition or nutritional biochemistry. The successful applicant will participate in one of the research programs within the Department. Curriculum vitae and names of three referees should be sent to Dr H. S. Bayley, Chairman of Search Committee, Department of Nutrition, College of Biological Science, University of Guelph, Guelph, Canada N1G 2W1 by January 1, 1979. Appointment subject to final budgetary approval. 8095(A)

THE UNIVERSITY OF LEEDS

UNIT FOR CANCER RESEARCH AND THE UNIVERSITY COMPUTING SERVICE

Applications are invited for a temporary fixed term post of POSTDOCTORAL RESEARCH FELLOW for work on a project under the supervision of Professor E. H. Cooper (Unit for Cancer Research) and Professor M. Wells (University Computing Service). The project, which is supported by the M.R.C., will involve the development of computer based systems for the handling and analysis of multivariate information used for the monitoring of cancer in man, and assistance in its application by clinicians. A Ph.D. degree or equivalent experience is required and it is essential that candidates should have experience in statistics and practical experience of computing. The post is for a fixed period of three years.

Starting salary in the range £3,883 to £5,219 on the LA Scale for Research and Analogous Staff (£3,883 to £6,555) (under review).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 89/2/D. Closing date for applications November 16, 1978. 8099(A)

Applications are invited for two permanent positions in the Laboratories of the

SWISS SERUM AND VACCINE INSTITUTE Berne, Switzerland VIROLOGIST

Candidates should have strong background in Tissue Culture and Virology. Areas of competence should include human diploid cell culture methodology, virus production and development.

BACTERIOLOGIST

Join a team engaged in the development and production of bacterial vaccines. Applicants should have university degree. Previous experience in immunology and preparation of vaccines would be essential.

We offer excellent benefits. Salary commensurate with experience. Send curriculum vitae, bibliography, and references to: The Personnel Manager, SWISS SERUM AND VACCINE INSTITUTE, BERNE, P.O. Box 2707, CH-3001 Berne, Switzerland. 8110(A)

BHP Australia

Director Central Research Laboratories

The Broken Hill Proprietary Co. Limited (BHP) is the largest company in Australia with annual sales of A\$2,374 million and employing some 59,000 people in a variety of activities, covering steel; minerals; oil and gas and manufacturing. These activities, which range through exploration, mining; extraction; transportation and fabrication, are supported by extensive research and development programmes.

As a result of the promotion of the present incumbent to an executive position in Head Office, a new Director is being sought for BHP Central Research Laboratories which are one of two corporate laboratories for the BHP Group. The Director will be responsible for the total research programme in raw materials and processes on behalf of the operations divisions of the BHP Group and for external organisations under contract. The research fields covered, include coal conversion; agglomeration; iron and steel-making; combustion; electrometallurgy and hydrometallurgy and analytical sciences.

The laboratories were established in 1956 and are located at Shortland N.S.W., adjacent to the University of Newcastle. They currently employ 160 people, of whom 55 are professionals. The laboratories are well equipped by world standards and are essentially self-contained with respect to services. Their annual budget is of the order of A\$3.5 million.

Applicants should have research experience and a proven record in management. Salary will be in the range A\$30,000-40,000 p.a. depending on experience and qualifications, and a company car is provided. The Company operates a generous superannuation scheme and reasonable relocation and removal expenses will be paid. Subsidised accommodation will be paid for up to six months on arrival in Australia.

Applications containing full personal particulars, including age, qualifications, experience, publications, telephone numbers and names of referees should be marked 'Confidential' and addressed to:-

Dr. R. G. Ward, General Manager Research and New Technology, The Broken Hill Proprietary Co. Ltd., P.O. Box 86A, Melbourne, Victoria, Australia.

Applications should reach the above address by 15th January, 1979.

8137(A)

EAST MALLING RESEARCH STATION A SOIL SCIENTIST

to initiate studies on the effects of modern orchard management practices on soil chemistry and physics.

Candidates should have a first or upper second class Honours degree or the equivalent in an appropriate subject and at least two years' relevant postgraduate research experience.

Appointment as Higher Scientific Officer (£4,101 to £5,558) or Senior Scientific Officer (£5,154 to £6,898), grade and starting salary depending on experience. At least four years' relevant postgraduate experience normally required for appointment as SSO. Non-contributory superannuation.

Further details and application form from Assistant to the Secretary, East Malling Research Station, East Malling, Maidstone, Kent, ME19 6BJ. 8178(A)

ROTHAMSTED EXPERIMENTAL STATION Harpenden, Herts. AL5 2JQ BIOLOGIST

in the Soil Microbiology Department to assist with applied aspects of work on the physiology of VA endophytes and the possibility of their pot culture in artificial media, and additionally, to investigate techniques for production, storage, and field application of inoculum. The appointment will be for 3 years.

Qualifications: Honours Degree or equivalent qualification in a biological subject with some practical experience in applied crop physiology. Manual dexterity and ability to construct simple apparatus would be desirable.

Appointment in grade of Scientific Officer (£2,839 to £4,415). Starting salary according to qualifications and experience. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref. 375 by November 17, 1978. Further details on request. 8173(A)

WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales) DEPARTMENT OF MEDICAL MICROBIOLOGY RESEARCH OFFICER

required from November 1, 1978 for a C.R.C.-supported 2-year research project involving studies on human tumour cells in culture and properties of hybrid cells prepared from them. Previous experience or a degree in biology or biochemistry is desirable. Starting salary for suitably-qualified applicants up to £4,133 per annum on the scale for University Research and Analogous Staff Grade 1B.

Application forms available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff (tel. No. Cardiff 755944 ext. 2073) quoting ref. No. B7/22, further information available from Professor Watkins (tel. No. Cardiff 755944 ext. 2168). 8132(A).

Environmental Science

An opportunity exists for a person, distinguished in some aspects of the physical environmental sciences, to join the Environmental Studies Section of our Planning Department at our London Headquarters. The Section is responsible for environmental policy formulation within the CEEB based on a sound understanding of scientific principles.

The Section consists of a small number of specialists in different scientific and engineering disciplines who collectively cover a broad spectrum of activities in the air, water, noise and nuclear fields. It is intended that the person appointed would take an interest in much of the scientific work of the Section as a whole, but specifically would study in depth some particular important environmental problem – possibly but not necessarily, the global CO₂ balance. In this he/she would need to collaborate with other experts in the CEEB, UK and throughout the world.

It is not envisaged that he/she would carry direct responsibility for the day-to-day activities of the Section. The post could well appeal to a senior University scientist of professional, or near, standing wishing to develop an understanding of the problems of a large organisation in caring for the environment in a responsible way. Equally it could appeal to an experienced industrial scientist wishing to broaden his/her experience. The appointment would be for a fixed term, the length of which might be up to three years. This aspect will be discussed with candidates called for interview.

The salary will reflect the seniority of the post and is unlikely to be less than £9000 p.a. and could be up to £11,000 p.a.

Applications stating full relevant details and present salary to the Group Personnel Officer, CEEB, Sudbury House, 15 Newgate Street, London EC1A 7AU, by 2 November. Quote Ref. NS/2103.

CENTRAL ELECTRICITY GENERATING BOARD HEADQUARTERS

6079(A)

UNIVERSITY OF ST ANDREWS DEPARTMENT OF CHEMISTRY

Applications are invited for a post of Postdoctoral Fellow to work on a project concerned with methods of modifying carbon fibre. The project is supported by the Ministry of Defence and will be run in close liaison with the Royal Aircraft Establishment, Farnborough.

The post is for one year in the first instance at a salary within the range £3,883 to £4,382 per annum plus U.S.S.

Applications, with the names of three referees, should be sent as soon as possible to Dr J. R. MacCallum, Department of Chemistry, Purdie Building, The University, St Andrews, Fife KY16 9ST, from whom further particulars may be obtained. 8116(A)

EUROPEAN MOLECULAR BIOLOGY LABORATORY E.M.B.L.

TECHNICAL ASSISTANT

Applications are invited for the post of technical assistant in the field of electron microscopy of nucleic acids in Dr Delius' research group.

Appropriate technical training together with knowledge of more than one of the official languages of the Laboratory (French, English, German) are required.

The salary offered will be between DM2,100 and DM2,600 monthly. Certain allowances are payable according to personal circumstances.

Please write for an application form, quoting reference no. 78/34 to:

E.M.B.L.,
Personnel Section,
Postfach 10.2209,
D-6900 Heidelberg,
Germany.

8170(A)

MAX-PLANCK-INSTITUT WEST BERLIN There is a vacancy for a PROTEIN CRYSTALLOGRAPHER

to work on the crystallisation and structure analysis of ribosomal proteins. Applicants should have experience in the analysis of protein structures.

The position is available from January 1979 and is initially for three years with the possibility of renewal.

Salary will be in the range of DM40,000 to DM50,000 per year.

Applications are invited giving information about qualifications and the addresses of 2-3 referees. They should be sent to Professor H. G. Wittmann, Max-Planck-Institut für Molekulare Genetik, Ihnstrasse 63-73, D-1000 Berlin 33, Germany. 8175(A)

PHYSICAL OCEANOGRAPHER

to fill vacant faculty post. Level of appointment commensurate with experience and qualifications. Applicant should have experience in the planning and execution of scientific cruises. Experience in one or more of the large, international oceanographic field programs desirable. Duties include teaching graduate level courses in physical oceanography and supervising the research of graduate students. Interested applicants should send curriculum vitae, including bibliography and two references, by November 30, 1978 to: Professor J. E. Gentry, Chairman, Division of Meteorology and Physical Oceanography, Rosenstiel School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, FL 33149.

The University of Miami is an Affirmative Action/Equal Opportunity Employer. 8093(A)

UNIVERSITY OF GLASGOW

DEPARTMENT OF CLINICAL ONCOLOGY RESEARCH ASSISTANT and POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the posts of Research Assistant and Postdoctoral Research Fellow, tenable for up to three years, for research on anti-metastatic drugs in animal tumour studies.

The Research Assistant should possess a good honours degree in a bioscience subject and will be expected to register for a higher degree. Starting salary £3,384 per annum.

The Research Fellow should possess experience in working with small animals and have recently obtained a Ph.D. degree in a bioscience subject. Starting salary £4,382 per annum.

Applications, together with two copies of a Curriculum Vitae and the names of two referees, should be sent to: Professor K. C. Calman, Department of Clinical Oncology, 1 Horsehill Road, Glasgow G12 9LY. 8155(A)

UNIVERSITY OF SURREY CHAIR IN PATHOLOGY

Applications are invited for this new Chair in Pathology in the Department of Biochemistry of the University, which is to be held in collaboration with the Medical Research Council Toxicology Unit, Carshalton, Surrey. Suitable candidates who would be medical or veterinary pathologists of considerable experience would be expected to contribute to existing teaching and research programmes in Toxicology and to develop new post-graduate activities in experimental and comparative Pathology.

An Honorary Consultant appointment with the South West Thames Regional Health Authority may be arranged for an appropriately qualified candidate and facilities in Human Pathology will be available within the local Guildford Hospital.

Salary will not be less than £9,443 per annum.

Further particulars may be obtained from the Academic Registrar (L.F.G.) University of Surrey, Guildford, Surrey GU2 5XH or telephone Guildford 71281, ext. 452. Applications from men and women in the form of a curriculum vitae including the names and addresses of three referees should be sent to the above address by November 24, 1978. 8159(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BOTANY Mineral Industries Research Organisation Research Project

Applications are invited for two posts of
SENIOR
RESEARCH ASSISTANT

to develop guidelines for the mineral extraction industry for the establishment of vegetation on (A) metalliferous wastes, (B) disused quarries, by field experimentation and literature survey. Applicants should have research experience in plant ecology, soil science or geochemistry, and be interested in working in collaboration with industry.

The project is financed for a period of two years. The initial salary will be either £3,883 or £4,133 per annum.

Applications, together with the names of two referees, should be received not later than November 17, 1978, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/974/N/A or B. 8166(A)

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research DIVISION OF MICROBIOLOGY

There is a vacancy for a
POSTDOCTORAL SCIENTIST

to join a small group studying genetic and molecular aspects of the replication and function of nuclear and mitochondrial genomes in yeast. Areas of interest include repair, replication and recombination of DNA in relation to both the vegetative cell cycle and meiosis, and current projects include studies on conditional DNA synthesis and cell cycle mutants.

The appointment will be for up to three years and will be in the salary range £4,655 to £6,080 per annum according to age and qualifications plus £450 p.a. London Allowance-Superannuation provision.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA, before November 30, 1978, quoting reference M1. 8097(A)

Wellcome

Helminthologist

Department of Parasitology

(£6,000 – £10,000)*

Applications are invited for the post of Section Leader of Helminth Chemotherapy in the Department of Parasitology (Head, Dr. R. A. Neal) of the Wellcome Research Laboratories located in Beckenham, Kent. The department is concerned with research for the control of selected veterinary and medical parasitic diseases by chemotherapeutic and immunological methods. There is a scientific staff of 16 covering biochemical, chemotherapeutic and immunological aspects of protozoal and helminthic infections.

The helminthologist appointed will be required to assume responsibility for chemotherapeutic studies covering a broad range of parasites and to initiate original research with particular emphasis on nematodes. Part of the work will involve collaboration within a multidisciplinary team.

Applicants should have substantial relevant experience and proven ability for original research. Interest in the biochemistry of nematodes would be advantageous but not essential. Candidates with biological, veterinary or medical backgrounds would be considered.

The Wellcome Research Laboratories are located in pleasant parkland surroundings 12 miles south of the centre of London. *Salary, dependent on ability and experience, will be in the range of £6,000 – £10,000. Fringe benefits are excellent and include generous relocation expenses where appropriate.

Please write, giving brief details of qualifications and experience, to the Personnel Manager, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS.

8188(A)

MASSEY UNIVERSITY

Palmerston North, New Zealand

LECTURER IN ENVIRONMENTAL HORTICULTURE

Applications are invited for the above-mentioned position in the Department of Horticulture and Plant Health, the Faculty of Agricultural and Horticultural Sciences.

The appointee will be required to assist with the teaching, at degree and diploma levels, all courses in the development and maintenance of ornamental plantings. Practical experience in these areas together with a strong background on plants and their use in the environment is required. An interest in landscape planning, design and construction would be desirable.

Commencing salary, according to qualifications and experience, within the range NZ\$11,894 to NZ\$14,488.

Further details of the position, and of the University together with the conditions of Appointment may be obtained from the Association of Commonwealth Universities (Acpu), 36 London Square, London WC1H 0PF, or the Registrar of the University. Applications close on December 2, 1978.

8183(A)

LECTURER IN CIVIL ENGINEERING

CONTINUUM MECHANICS

A vacancy exists in the Department of Civil Engineering for a Lecturer with a background in Theoretical Continuum Mechanics and a productive research interest in this field relevant to Civil Engineering.

The Department has well established analytical and experimental groups working in this area and the person appointed would, therefore, be able to collaborate immediately with active colleagues.

In addition, he/she would be required to teach Mechanics in the Department at both undergraduate and postgraduate levels.

Salary on scale £3,884 to £7,754 (under review) according to qualifications and experience.

Further particulars may be obtained from D. A. S. Copland, The University, Southampton SO9 5NH to whom applications (seven copies from UK applicants) should be sent by November 30, 1978. Please quote reference number 168/A/Na. 8084(A)

HEAD OF PHARMACOLOGY DEPARTMENT

A leading Spanish Pharmaceutical Company situated in the Mediterranean city of Barcelona invites applications from pharmacologists for the above post in a Pharmacology Department. The man we appoint will have a good honours degree in an appropriate discipline, a Ph.D. in pharmacology and several years postdoctoral experience preferably in the pharmaceutical industry.

The successful applicant will be responsible to the director of Biological Sciences and must be able to formulate and organise research and development projects and collaborate with the other departments in the Biological and Chemical science groups.

Knowledge of Spanish is not initially essential but the successful candidate must be prepared to acquire adequate fluency in this language within 2 years. The salary is tax free and negotiable at around 30,000 dollars p.a. and special assistance will be given for removal expenses to Barcelona.

Applications in writing with full curriculum vitae should be addressed to:

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the temporary post of

DEMONSTRATOR

in the above Department from suitably qualified candidates. The person appointed will participate in teaching biochemistry to science and to medical students and will also be expected to carry out research on the molecular biology of bacterial drug resistance in collaboration with Dr J. H. Parish. The post is tenable from January 1, 1979 until September 30, 1979. Salary at an appropriate point on the IB Scale for Other Related Staff (£3,384 to £5,604) (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University of Leeds, Leeds LS2 9JT, quoting reference number 83/16/D. Closing date for applications November 6, 1978. 8002(A)

PHYSIOLOGIST

Ph.D. needed in active Hematology Laboratory, Thomas Jefferson University, Philadelphia, Pa., with experience in measurements of platelet size, morphology, and functions related to the evaluation of patients and platelet transfusion. Minimum salary, \$15,000 plus commensurate with experience. Excellent employee benefits. Send detailed resume with salary requirements to Mr Burvin Hardy, Bureau of Employment Security, 1709 S. Broad Street, Philadelphia, Pa. 19148. Affirmative Action/Equal Opportunity Employer. 8119(A)

UNIVERSITY OF MIAMI ASSISTANT/ASSOCIATE PROFESSOR

DEPARTMENT OF BIOLOGY

Three new positions available 1979 in research-oriented department emphasising organism-level studies.

1. **TROPICAL FOREST BIOLOGIST.** Botanist with research interests in community ecology or forest structure preferred. Appropriate areas can include succession dynamics, seed dispersal, competition, plant-animal interactions, co-evolution, phenology, etc.

Preference for the following positions given to candidates with a demonstrated interest in tropical organisms.

2. **VERTEBRATE PHYSIOLOGIST.** Interdisciplinary research in behaviour, neurobiology, or ecology preferred.

3. **EVOLUTIONARY BIOLOGIST/POPULATION GENETICIST.** Specific interests might include genetic structure of populations, dynamics of natural selection, reproductive life history strategies, etc.

Candidates must have Ph.D. or equivalent and an active research program. Competitive salary based on qualifications and experience. Apply before January 10, with curriculum vitae, a recent reprint, and names of four references (have overseas letters of recommendation sent immediately) to: Search Committee for [position sought], Department of Biology, Box 249118, University of Miami, Coral Gables, Florida 33124, USA. Equal Opportunity Employer. 8121(A)

UNIVERSITY OF GLASGOW SECOND CHAIR OF PSYCHOLOGY

Applications are invited from those with experience and interest in any area of Psychology for a Second Chair which will be established on October 1, 1979.

Further particulars may be had from the Secretary of the University Court (Room 18), The University of Glasgow, Glasgow G12 8QQ, to whom applications (15 copies) giving the names and addresses of three referees, should be lodged on or before December 12, 1978.

In reply please quote Ref. No. 4265M. 8102(A)

TELEPHONE: 01 831-6901

SENIOR RESEARCH FELLOW IN ATOMIC/MOLECULAR PHYSICS

The University of Maryland and the National Bureau of Standards in Washington, D.C. are announcing a one year fellowship for a senior research scientist to pursue research at the N.B.S. Synchrotron Ultraviolet Research Facility (S.U.R.F.). The S.U.R.F. fellow will hold an appointment in the Institute of Physical Science and Technology at the College Park campus of the University of Maryland. In addition to his research duties at S.U.R.F., the appointee will interact with the faculty and students at the University, principally through lectures and seminars.

Applications are now being accepted for the academic year '79-80, with detailed schedule to be negotiated. Salary and faculty rank will be commensurate with current position. We are initially seeking an individual interested in pursuing atomic/molecular physics at S.U.R.F. Experience in the use of synchrotron radiation and/or photoelectron spectroscopy of gases will be considered particularly valuable for the appointment.

Send résumé, desired starting date, and research plans to Professor Joseph Silverman, Institute for Physical Science and Technology, University of Maryland, College Park, Maryland 20742 8122(A).

TECHNICIAN

Required at our Mill Hill Laboratories, London NW7, to join group working on experimental embryology and regeneration. Work will involve some animal maintenance (amphibia), histology, photography, laboratory maintenance and experimental work.

H.N.C./Degree Laboratory experience an advantage. Salary range 3,261 to £4,902 L.W. Application form from Mrs Nelson, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2, Tel. 242 0200 ext 305, quoting ref 13/79. Closing date for applications November 7, 1978 8033(A).

INSTITUTE OF CANCER RESEARCH SUTTON, SURREY DIVISION OF EPIDEMIOLOGY SCIENTIST FOR COMPUTER SIMULATION

A health-hazard monitoring system in industrial situations. A small research team will undertake this project, to study design and analysis of such an information system using simulation techniques. Applicants should preferably have a degree in mathematics or statistics, probably an M.Sc. or experience relevant to mathematical modelling of medical statistics. The post is for two years, with salary in the range £3,909 per annum to £4,408 per annum plus London allowance of £450 per annum, as an R.C. Grade II scientist. Further details available from Mrs Bell (01-643 8901, ext 291). Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Cancer Place, London SW7 3NT, quoting ref 300/G/134. Closing date for applications November 10 1978 8138(A).

Wellcome Clinical Research Associate—Vaccines and Sera

The Wellcome Foundation has been a pioneer in the development of vaccines and sera for immunisation against infectious disease for over 80 years and has made many original scientific contributions in this field.

We currently have an opportunity for a Clinical Research Associate in the Department of Clinical Immunology & Chemotherapy of our Research Laboratories located in Beckenham, Kent. The successful candidate's main duties will include

- the identification and recording of scientific and clinical reports related to the Foundation's interest in vaccines and sera,
- the preparation of authoritative and critical scientific reviews,
- participation in reviews of clinical research projects,
- dealing with some technical queries;
- assisting in the administration of clinical trials/data handling in association with the responsible physician.

Candidates should have a degree in a biological science and some years postgraduate experience in a relevant field e.g. virology, bacteriology or immunology. A knowledge of immunological theory and the nature, clinical characteristics and usage of vaccines would be particularly advantageous.

The Laboratories are situated in pleasant parkland surroundings some 12 miles south of the centre of London. Starting salary will depend upon age and experience but is not expected to be less than £4,250 p.a. Conditions of employment are excellent and include generous relocation expenses where appropriate, pension scheme, subsidised canteen and sports and social facilities.

For an application form, please write to:—

Personnel Manager,
Wellcome Research Laboratories,
Langley Court,
Beckenham, Kent.
BR3 3BS.

8184(A)

ONLINE TRAINING OFFICER

To conduct training sessions with Commonwealth Agricultural Bureaux staff and customers, and organise exhibits and displays. Subjects covered include all of C.A.B.'s products and services, particularly online information retrieval.

Applicants should be graduates in agricultural science or related subject. You must be a car owner, with a clean driving licence. Although based at Farnham Royal the position demands considerable travel in the UK and overseas for which allowances will be paid.

A knowledge of one or more European languages would be advantageous.

Salary in the scale £2,839 to £5,448 per annum Superannuation 22 days' annual leave.

Apply to Sales Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal Slough SL2 3BN 8151(A).

UNIVERSITY APPOINTMENTS IN NEW NIGERIAN UNIVERSITIES

The Inter-University Council intends to extend its register of candidates available for posts in the new and developing universities in Nigeria. Applicants should possess a good Honours Degree and research experience preferably with a Doctorate. University level teaching experience is desirable for Lectureship posts and essential for Senior Lectureships. The universities in question are often developing faster than the supporting infrastructure and a pioneering approach is essential. Applicants on the basis of possible secondment from a British university/polytechnic would be welcomed.

Applicants are invited for posts of Lecturer and Senior Lecturer in the following subjects:

- | | |
|----------------|---------------------------|
| B1 MATHEMATICS | B6 GEOLOGY |
| B2 PHYSICS | B7 MECHANICAL ENGINEERING |
| B3 CHEMISTRY | B8 ELECTRICAL ENGINEERING |
| B4 BOTANY | B9 CIVIL ENGINEERING |
| B5 ZOOLOGY | |

Salary range £4,350 p.a. to £6,905 p.a. plus 25 per cent Contract Bonus. Salary may be supplemented in appropriate cases for posts at Senior Lectureship level.

Appointments normally on contract for 2/3 years renewable. Paid overseas passages every 2 years, car loan, car allowance, furnished accommodation at low rental as available.

Further information and form from Division A, Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Closing date December 1, 1978.

Candidates living outside the United Kingdom should not apply to the I.U.C. but to the universities in Nigeria directly. The universities concerned are those at Calabar, Ilorin, Jos, Kano, Maiduguri, Port Harcourt, Sokoto 8180(A).

RESEARCH TECHNICIAN

IMMUNOLOGY DEPARTMENT

at ROYAL VICTORIA HOSPITAL
BOURNEMOUTH

A temporary research assistant medical laboratory scientific officer is required for the Department of Pathology in Immunology at the above Hospital. The post is for approximately a five months period only and is to assist in the Department's Regionally Financed Programme. Knowledge of column chromatography and radio-immune assay is essential.

Normal working hours will be 9.00 a.m. to 5.30 p.m. Monday to Friday inclusive.

Closing date for receipt of applications 9th November 1978

Application forms and job descriptions are obtainable from Miss M. Smith, Staff Appointments Officer, Royal Victoria Hospital, Shelley Road, Bournemouth BH1 4JG. Tel: 0202 35201 ext. 381 (between 9.00 a.m. and 4.00 p.m. Monday to Friday only). 8101(A)

DALHOUSIE UNIVERSITY DIRECTOR OF ENGINEERING PHYSICS PROGRAMME

Applications are invited for the position of Director of the programme in Engineering Physics within the Department of Physics, Faculty of Arts and Science. Candidates should have a doctoral degree in Engineering Physics or closely allied field, be eligible for registration as a professional engineer and have suitable industrial experience and inventive ability. Teaching involves both undergraduate and graduate students. Appointment at the associate or full professor level, with salary according to qualifications and experience, commencing July 1, or September 1, 1979. Canadian citizens and landed immigrants are particularly urged to apply. Enquiries or applications should be sent as soon as possible to The Dean, Faculty of Arts and Science, Dalhousie University, Halifax, Nova Scotia, Canada B3H 3J5. 8111(A)

ST THOMAS'S HOSPITAL MEDICAL SCHOOL (University of London) London SE1 7EH

Applications are invited from medically or scientifically qualified persons for the post of

RESEARCH ASSOCIATE

in the Department of Chemical Pathology and Metabolic Disorders. The successful candidate will work with Professor B. Lewis and Dr N. Miller on cholesterol and lipoprotein metabolism in tissue culture on a topic which would be suitable for a doctoral thesis. Preference will be given to applicants with previous research experience in cell biology, but such experience is not essential. Salary on University scale for Research staff, plus London Allowance. Further information from Professor Barry Lewis (Tel: 01-928 9292 ext. 2264) to whom applications (3 copies with the names of 2 referees) should be forwarded by November 25, 1978. 8115(A)

NEUROANATOMIST THE DEPARTMENT OF PHYSIOLOGY-ANATOMY UNIVERSITY OF CALIFORNIA, BERKELEY

invites applications and nominations for the position of Assistant Professor of Anatomy which will become available July 1, 1979, pending final budgetary approval. The successful candidate must be able to assume primary teaching responsibility for one undergraduate and one graduate neuroanatomy course in alternate years, and to participate in the Department's teaching program in the anatomical sciences. Preference will be given to applicants with two or more years of postdoctoral training and research competence in developmental and/or functional anatomy of the nervous system. Candidates will be evaluated on the basis of their dedication to excellence in teaching and research, and their capacities to develop a vigorous and independent research program in neurobiology. Interested individuals should reply by letter, explaining their qualifications, with a current curriculum vitae and a list of three or more persons who could act as referees, to: Search Committee, Department of Physiology-Anatomy, 2549 Life Sciences Building, University of California, Berkeley, California, 94720. Deadline for applications and nominations: January 1, 1979. The University of California is an affirmative Action Employer. 8117(A)

LANCHESTER POLYTECHNIC AT COVENTRY DEPARTMENT OF BIOLOGICAL SCIENCES POSTDOCTORAL RESEARCH FELLOW

Salary within the range: £4,101 to £6,558 (it is only possible to appoint on the minimum of this scale). Tenable for three years, from January 1, 1979.

RESEARCH TECHNICIAN

Salary £3,279 to £4,146 T2/3. Tenable for three years from January 1, 1979.

To participate in a joint project S.R.C. and I.C.D. involving development of a method for the *in vitro* culture of perfused hepatocytes supported in a 3 dimensional matrix as an application to toxicological studies. Applicants for both posts should offer experience in animal cell culture and in biochemistry. Knowledge of cytological procedures would also be an advantage.

Applicants for the Research Technician post should possess an H.N., H.N.D. or degree in an appropriate subject.

- * Good working conditions.
- * City centre site.
- * Refectory facilities.

For application forms and further particulars please apply in writing enclosing a foolscap stamped addressed envelope to the Personnel Officer, Lanchester Polytechnic, Priory Street, Coventry. Applicants in contact Dr. Sturdee or Dr. Cris informally by telephoning the Polytechnic (Coventry 24166).

Closing date for applications: November 13, 1978. 8123(A)

UNIVERSITY OF OXFORD DEPARTMENT OF PHYSICS

CLARENDON LABORATORY

A post is available to work as Postdoctoral Research Officer in a group concerned with the chemical and physical principles of wear during machining with diamond and other materials. The post, which is for period of two years, involves a limit amount of demonstrating, and requires an interest in both physical and chemical principles and their application to engineering practice. Scale £3,384 to £4,466 (under review starting point, according to age, e.g. £3,883 at age 24).

Application, with curriculum vitae and names of two referees, should be sent to Dr J. Wilks, Clarendon Laboratory, Oxford, OX1 3PU, from whom further details may be obtained. 8139(A)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF GEOGRAPHY LECTURESHIP

Applications are invited for the post of Lecturer in Urban Geography. Preference may be given to candidates with mathematical or statistical interests.

Salary will be in the range £3,800 to £7,754, plus superannuation. Maximum starting salary will be according to age, experience and qualifications.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (the copies) including full curriculum vitae and naming three referees, should be sent by Monday, November 27, 1979. Please quote ref. NH4. 8124(A)

COMMONWEALTH
AGRICULTURAL BUREAUX
Vacancy for
SCIENTIFIC INFORMATION
OFFICER

at the

COMMONWEALTH BUREAU
OF ANIMAL HEALTH

Central Veterinary Laboratory,
New Haw, Weybridge, Surrey

General Information. The work of the Bureau is to collect and make available through its publications the *Veterinary Bulletin* and *Index Veterinarius* and by magnetic tape services, information relating to all aspects of veterinary science.

Main duties. The duties include archiving scientific periodicals, indexing articles, preparing English-language abstracts for the monthly journal *The Veterinary Bulletin*, editorial work, dealing with enquiries and preparing reviews and bibliographies.

Qualifications. A qualification in information science or an appropriate biological science is required, plus a knowledge of European and Slavonic languages or a willingness to learn languages.

Salary. In the scale £2,839 to £5,448 per annum plus an Outer London weighting allowance of £275 per annum, plus a compensatory allowance taxable but not superannuable) of 3% to offset personal contribution.

Superannuation Scheme—part-time appointment *pro rata*. Starting salary according to qualifications, experience and age.

Application forms and full particulars on the Executive Director, Commonwealth Agricultural Bureaux, Pirbright House, Pirbright, Woking, Surrey, SL2 3BN, to whom completed applications (in duplicate) should be sent by November 27, 1978.

Laboratory Head— Biochemistry New Fermentation Products

The Glaxo Group of companies has an impressive history of exploiting fermentation products. Our Fermentation Research Division, situated in pleasant surroundings at Stoke Poges in South Buckinghamshire, has an extensive programme to investigate the biosynthetic potential of a variety of micro-organisms.

We are seeking an experienced research microbiologist, with a good innovative record, capable of supervising a graduate and technical staff and able to liaise with biochemists, chemists and fermentation technologists within a progressive multi-disciplinary research group.

The successful candidate will be responsible for organising and reporting the work of a laboratory and should combine an understanding of microbial metabolism and the optimisation of secondary metabolites in liquid culture with a capacity for a critical evaluation of the potential of selected organisms for new product formation.

Starting salary will be in the range of £5,320 p.a. to £7,073 p.a. subject to qualifications and experience. In addition there is a London Allowance of £258.50 p.a. and pension and bonus schemes. Assistance with relocation expenses will be given where appropriate.

Please apply to:

Mr. R. E. Nolan
Personnel Officer
Glaxo Allenburys Research (Greenford) Ltd.
Greenford Road,
Greenford
Middx.

Quoting reference number: 247

8186(A)

Glaxo-Allenburys Research (Greenford) Limited

LABORATORY TECHNICIAN for duties including assisting research staff and helping run student practical classes. Applicants should possess H.N.C. or equivalent qualification and relevant experience. Salary on Whitley Council Scales depending upon qualifications and experience. Applications in writing with names of two referees to: Mr S. W. Phillpot, Department of Physiology, The Middlesex Hospital Medical School, Windeyer Building, Cleveland Street, London W1P 7PN.

8086(A)

UNIVERSITY OF LONDON
KING'S COLLEGE
DEPARTMENT OF
PHYSIOLOGY

Applications are invited for a newly created Lectureship in Physiology. The Department of Physiology is engaged in teaching medical, dental and science students and has good facilities for research. Applicants should preferably have an interest in and be able to teach Mammalian Physiology. Candidates active in inter-disciplinary fields such as genetic, developmental or behavioural physiology will not be excluded. A medical qualification although desirable is not essential.

Salary scale £3,883 to £7,754 per annum plus £450 per annum London Allowance. The starting salary will be at an appropriate point on the scale. Universities Superannuation Scheme contributions would be payable.

Application forms and further particulars are available from the Assistant Registrar, King's College London, Strand, London WC2R 2LS and should be returned with any additional information, in triplicate, to reach him not later than Friday, December 1, 1978 quoting reference 191647/N.

8087(A)

UNIVERSITY OF
NEWCASTLE UPON TYNE
SCHOOL OF PHYSICS

Applications are invited for the post of Research Associate to continue studies in Lunar Magnetism and Seismology.

The School of Physics has a programme for the study of the magnetism of lunar rocks and is concerned over the theoretical consequences of early lunar magnetic field for the understanding of the evolution of the interior of the moon and its present internal activity.

The appointment will be for one year only, at a salary of £4,882 plus F.S.S.U. and National Insurance, and will be made from a mutually agreed date.

Applications (two copies) together with names and addresses of two referees should be sent to Professor S. K. Runcorn, School of Physics, The University, Newcastle upon Tyne NE1 7RU, as soon as possible.

8112(A)

THE UNIVERSITY of Leeds—Department of Plant Sciences. Applications are invited for the post of Grade 4 Technician in Photography. The person appointed will be in charge of Departmental Photography, including enlargement printing for light and electron microscopy, reduction printing for lantern slides, colour and B/W photography of plant material, and general care and supervision of all darkroom facilities. Applicants should possess an appropriate qualification and have had about seven years relevant experience including a training period. Salary on the scale £2,955 to £3,402 a year. Applications with the names of two referees and full details of qualifications and practical experience should be submitted to The Secretary, Department of Plant Sciences, Baines Wing, The University, Leeds LS2 9JT.

8133(A)

ECOLOGY

YALE UNIVERSITY

DEPARTMENT OF BIOLOGY

seeks candidates for senior and junior appointments in Ecology. The appointees will be expected to contribute to a strong program of research and scholarship in ecology, and participate in undergraduate and graduate teaching.

Send curriculum vitae, résumé of past and present research, and names of referees to: The Chairman, Department of Biology, 102 KBT, Yale University, New Haven, Connecticut 06520. Deadline for receipt of applications is June, 1979.

Yale University is an Equal Opportunity Affirmative Action Employer. We invite applicants from all qualified individuals, especially women and members of minority groups.

TELEPHONE : 01 831-6901

AGRICULTURAL RESEARCH COUNCIL ANIMAL BREEDING RESEARCH ORGANISATION

Applications are invited for a vacancy in the Department of Growth and Efficiency for work on the genetics of growth and productive efficiency of livestock.

Candidates should have a first or upper second class Honours Degree or the equivalent in an appropriate subject and at least two years' post-qualifying experience in mathematics, statistics, genetics or animal science. They should have the ability to conduct and direct large-scale experiments on cattle fed a controlled complete diet. An ability to analyse data and use extensive computing facilities is essential.

Appointment as Higher Scientific Officer (£4,101 to £5,448), starting salary depending on experience. Non-contributory superannuation.

Further information and application forms are available from the Secretary, ARC Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ. Closing date November 11, 1978. 8012(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF ZOOLOGY

Applications are invited for two Demonstratorships for persons working in the fields of Behavioural Ecology and Vertebrate Physiology respectively, to take up appointment by October 1, 1979. Appointments will be for three years, with the possibility of re-appointment for two years. Proposed pensionable stipend £4,133 to £5,129 according to age and experience.

Further information about Cambridge Demonstratorships and about the duties and conditions of appointment may be obtained from the Secretary of the Appointments Committee, Faculty of Biology "A", Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX, to whom candidates should send their applications (six copies), together with curriculum vitae and the names of two or three referees, by January 12, 1979. 8156(A)

UNIVERSITY OF KENT AT CANTERBURY BIOLOGICAL LABORATORY

Protozoology Group
Applications are invited for the following research posts.

POSTDOCTORAL RESEARCH FELLOW

to work on the biochemistry of pyrimidine biosynthesis in *Trypanosoma cruzi*. Preference will be given to candidates with experience in enzymology or nucleic acid metabolism. Salary scale £3,883 to £6,555.

GRADUATE RESEARCH ASSISTANT

to work on various aspects of the biochemistry of *Trypanosoma cruzi*. Candidates with degrees in biochemistry will be preferred. Salary scale £3,384 to £4,882.

The appointments will be initially for one year with a good prospect of extension for a further period of two years. Training in protozoological techniques will be provided.

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH, to whom completed applications should be returned by November 17, 1978. Please quote ref. A37/78. 8105(A)

TECHNICIAN GRADE 3, required in M.R.C. Neuroimmunology Project. Work will involve the identification, purification and *in vitro* culture of cells from nervous tissue using immunological and biochemical techniques. Salary in range £3,153 to £3,525 inc. of London Weighting (under review). This appointment is supported by grant funds. Application form from Personnel Officer (Technical Staff CM17), University College London, Gower Street, London WC1E 6BT. 8152(A)

TECHNICIAN Grade 5, with knowledge of Cytology required to assist in both the research and undergraduate teaching laboratories in the Dept. of Botany and Microbiology. It is essential for applicants to have a sound knowledge of Cytological Techniques. Salary according to experience in range £3,651 to £4,185 inc. of London Weighting (under review). Application form and further details from Personnel Officer (Technical Staff CD9), University College London, Gower Street, London WC1E 6BT. 8153(A)

Please mention

Applications are invited for the position of:

PROJECT LEADER

in a DRUG METABOLISM AND PHARMACOKINETICS GROUP with a leading pharmaceutical company in Paris.

The applicant should have a particular knowledge of h.p.l.c. methods of analysis and a PhD degree in a relevant discipline.

Send applications and CV to NATURE, Box No 8106(A), 3, Dyers Buildings, London EC1N 2NR.

All replies will be treated in the strictest confidence. 8106(A)

ROTHAMSTED EXPERIMENTAL STATION Harpenden, Herts. AL5 2JQ BIOCHEMIST

In Soil Microbiology Department to study the physiology of VA endophytes and the possibility of their culture in artificial media. The post is tenable for approximately 3 years and is funded by the Ministry of Overseas Development.

Qualifications: First or upper second class Honours degree or the equivalent and at least two years' postgraduate experience. Preference will be given to candidates with appropriate post-doctoral experience in plant or microbial biochemistry and/or root physiology.

Appointment in grade of Higher Scientific Officer (£4,101 to £5,448) or Senior Scientific Officer (£5,154 to £6,898), grade and starting salary depending on experience. At least four years' postqualifying experience would normally be required for appointment as S.S.O. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref 374 by November 24, 1978. Further details on request. 8172(A)

PRE AND POSTDOCTORAL POSITIONS

are available for studies on the protein synthesizing system with special emphasis on ribosomes—topography, biogenesis and function—under various conditions of growth and development. Teaching opportunities available. Reply with résumé to:

Professor Bruce H. Sells,
Laboratories of Molecular Biology,
Faculty of Medicine,
Health Sciences Complex,
Memorial University
of Newfoundland. 8003(A)

THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S HOSPITAL

DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

Applications are invited for a Research Assistant to participate in a research programme on Cancer of the Ovary. This post in the Williamson Laboratory is suitable for a Science Graduate, preferably with some experience in laboratory immunology. The post is funded by a grant from the Cancer Research Campaign which is subject to renewal.

Further particulars may be obtained from: Mr T. A. Poulton, Williamson Laboratory and applications should be sent to The Secretary, The Medical College of St Bartholomew's Hospital, West Smithfield, London EC1A 7BE, quoting reference 807. 8098(A)

INTERNATIONAL INSTITUTE OF HUMAN NUTRITION TECHNICIANS

for lipid analyses and for clinical biochemistry.

Applications stating qualifications, age and experience to Director, International Institute of Human Nutrition, High Street, Sutton Courtenay, Abingdon, Oxon OX14 4AW. 8165(A)

UNIVERSITY OF RHODES DEPARTMENT OF GEOGRAPHY SENIOR LECTURESHIP ON LECTURESHIP IN GEOGRAPHY

Applications are invited for one post in human geography tenable from January 1979. Preference may be given to persons whose special fields of study include one or more of the following: cultural, urban, political geography. Interested persons should indicate their applications the full range of their interests and abilities in teaching and research, including any pertinent to regional courses.

Salary Scales (approx. std. equiv. Senior Lecturer, £7,544 to £9,900; Lecturer Grade I, £6,843 to £7,877; Lecturer Grade II, £4,224 to £6,611). Both permanent, pensionable terms of short-term one- or two-year contracts are offered.

Further particulars and application procedure should be obtained from the Association of Commonwealth Universities (AppUs), 36 Gordon Square, London WC1H 0PF.

Closing date for receipt of applications: November 30, 1978.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233 4143), their nearest British Consular Office. 8081(A)

MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH DIVISION OF VIROLOGY

A scientific staff vacancy exists in a small team studying the mechanism of virus infection using the adenovirus model system. We require someone who has had experience in virologic and/or biochemical techniques as well as some expertise in gene engineering (our Category III laboratory will be available shortly).

The appointment will be for up to three years and will be in the salary range £4,655 to £6,090 per annum according to age and qualification plus £450 per annum London Allowance.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before November 30, quoting reference V.1. 8096(A)

WEST OF SCOTLAND HEALTH BOARDS DEPARTMENT OF CLINICAL PHYSICS AND BIO-ENGINEERING POSTDOCTORAL RESEARCH WORKER

Applications are invited for a funded post to study the uptake, methylation and excretion of mercury in biological systems, with special reference to mercury hazards in food practice. Experience of G.L.C. would be advantageous.

Salary scale £3,915 to £4,395 p.a. annum (three year appointment N.H.S. superannuation scheme).

Application form and job description may be obtained from the Director, Department of Clinical Physics and Bio-Engineering, 11 West Graham Street, Glasgow G4 9LF, to whom completed applications should be returned by November 30, 1978. 8100(A)

PALEONTOLOGIST

Salary: \$16,500 to \$39,517 (depending on experience)
Ref. No: 78-RES-63 (N)

**Energy, Mines and Resources, Geological Survey of Canada
Calgary, Alberta**

A scientist is required at the Institute of Sedimentary and Petroleum Geology to conduct research in Western and Northern Canada on marine molluscan faunas from the Cretaceous period. The successful candidate will investigate phylogenetic relationships of fossils through detailed field and taxonomic studies, and will develop and apply biostratigraphic models for paleoecological assessment and for local, regional and world-wide correlation.

Qualifications

Applicants must possess a Ph.D., or have a lesser degree with evidence of research experience and productivity equivalent to a doctorate in geology or paleontology with specialization in molluscan faunas. Experience and demonstrated ability in paleontological studies of Cretaceous cephalopods and pelecypods is essential. Knowledge of English is essential.

**RESEARCH SCIENTIST —
ORGANIC GEOCHEMISTRY**

Salary: \$15,230 to \$36,760 (depending on experience)
Ref. No: 77-PSTP-32-153 (N)

**Fisheries and Environment Canada
Burlington, Ontario**

A research scientist is required in the Process Research Division of the National Water Research Institute to study the physical-chemical processes involving organic matter in recent and modern sediments associated with aqueous systems. Emphasis will be placed on the carbon cycle and studies will be undertaken in lakes and rivers in support of national water management programs. The incumbent also provides advice and assistance in the development of optimal water resource management strategies.

Qualifications

Applicants must possess a Ph.D. or lesser degree with evidence of research experience and productivity equivalent to that of the Ph.D. in geochemistry or a closely related field. Experience and research productivity in the field of organic geochemistry is also required. Knowledge of English is essential.

THE DEPARTMENT OF ZOOLOGY
of the University of California, Davis
announces the vacancy of an
**ASSISTANT
PROFESSORSHIP**
in the area of
**DEVELOPMENTAL
BIOLOGY**

The Department of Zoology invites applications from persons with primary interests and experience in research and teaching in any area of developmental biology. The appointee is expected to establish a productive research program and to participate in the department's program of graduate instruction. Teaching responsibilities include a one-quarter introductory course in embryology, a one-quarter advanced course in developmental biology, and participation in a graduate seminar in developmental biology. Candidates must have a Ph.D. degree. Salary will depend upon qualifications and experience.

Applicants should forward a curriculum vitae, a description of their research experience and future research plans, reprints of all publications, a summary of teaching capabilities, and three letters of recommendation to Dr. R. D. Grey, Chairperson of the Search Committee, Department of Zoology, University of California, Davis, California 95616. The University of California is an equal opportunity/affirmative action employer. Closing date for receipt of applications is November 30, 1978.

COMPLIANCE STATEMENT

The University of California, Davis, in compliance with Titles VI and VII of the Civil Rights Act of 1964, Title IX of the Education Amendments of 1972 (45 CFR 86), and Sections 503 and 504 of the Rehabilitation Act of 1973, does not discriminate on the basis of race, color, national origin, religion, sex, or handicap in any of its policies, procedures, or practices, nor does the University, in compliance with the Age Discrimination in Employment Act of 1967 and Section 402 of the Vietnam Era Veterans Readjustment Act of 1974, discriminate against any employee or applicants for employment on the basis of their age or because they are disabled veterans or veterans of the Vietnam era. This nondiscrimination policy covers admission, access, and treatment in University programs and activities, and application for and treatment in University employment. In conformance with University policy, and pursuant to Executive Orders 11246 and 11376, Section 503 of the Rehabilitation Act of 1973, and Section 402 of the Vietnam Era Veterans Readjustment Act of 1974, the University of California is an affirmative action/equal opportunity employer. Inquiries regarding the University's equal opportunity policies may be directed to the Vice Chancellor of Academic Affairs and Affirmative Action Officer, 515 Mraz Hall, 752-2070, the Vice Chancellor of Student Affairs and Title IX Compliance Officer, 541 Mraz Hall, 752-2417, the Rehabilitation Act Compliance Coordinator, Office of the Chancellor, 581 Mraz Hall, 752-6560, or the Director, Office of Civil Rights, DHEW 8189(A).

**UNIVERSITY OF
NOTTINGHAM
DEPARTMENT OF
CHEMISTRY
MASS SPECTROMETER
TECHNICIAN GRADE 5**

Applications are invited for this post which involves the operation and maintenance of an MS902 mass spectrometer. This post offers interest in an important aspect of the analytical services required by the Department. Experience in the use of mass spectrometers or in the general field of analytical instrumentation would be desirable although not essential. Excellent working conditions are offered with a starting salary within the scale £3 186 to £3 720 p.a. (under review).

Applications in writing giving full details and the names of two referees should be sent to the Establishment Officer, University of Nottingham, University Park, Nottingham NG7 2RD 8081(A).

**RESEARCH FELLOW
IN PSYCHOLOGY
RESEARCH PSYCHOLOGIST**

required for one year from December 1, 1978 for a study of the behavioural aspects of infant feeding based in the JOHN RADCLIFFE HOSPITAL, OXFORD. The project is supported by the International Council for the Infant Feeding Industries and supervised by Dr R. F. Drewett (Department of Psychology, University of Durham) and Dr J. D. Baum (Department of Paediatrics, University of Oxford). The appointee will be a Research Fellow of the University of Durham, working in Oxford. Applicants should have a Ph.D. or equivalent research experience in psychology or a related subject.

Salary in the range £3,883 to £4,382 per annum on National Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by November 10, 1978, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained 8083(A).

FELLOWSHIPS

**UNIVERSITY OF
BIRMINGHAM
DEPARTMENT OF
ZOOLOGY AND COMPARATIVE
PHYSIOLOGY
S.R.C. RESEARCH
FELLOWSHIP**

Applications are invited for a Postdoctoral Research Fellowship to work on the function of avian retinal oil droplets. The research will involve the determination of oil droplet characteristics and visual capacities in birds, with a view to exploring the relationships between sensory physiology, visual capacities and behavioural ecology. Previous experience with animal training procedures would be an advantage.

Candidates would have a Ph.D. in either Zoology, Psychology or Physiology Appointment, for three years from December 1, or as soon as possible thereafter, on the Research Fellow Grade 1A, £3,883 to £6,555, plus superannuation. Maximum starting salary £4,382.

Further particulars from the Assistant Registrar (Science and Engineering), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (three copies) containing full curriculum vitae and naming three referees should be sent by Friday, November 10, 1978. Please quote ref. NJ6 8125(F).

**POSTDOCTORAL
FELLOWSHIPS**

Two three-year postdoctoral fellowships are available at the Fried Miescher-Institut, Basel, in a study correlating between structure and function in synaptic junctions from mammalian brain.

Biochemist. Preferably experienced in membrane biology, sub-cell fractionation and gel electrophoresis. Experience in immunochemistry, protein chemistry would be relevant. A grasp of the principles of light and electron microscopy would have to be developed and appropriate training will be given where necessary.

Electron Microscopist. Prefers with experience of CNS ultrastructure. Experience of quantitative methods immunohistochemical procedures would be relevant. Candidates should be prepared to utilize light microscopy; classically should a particular problem demand it.

Reply to Dr A. I. Matus, Friedrich Miescher-Institut, P.O. 1 273, CH-4002 Basel, Switzerland sending a brief cv and names of three referees 8163(E).

**UNIVERSITY OF
STRATHCLYDE**

Applications are invited for a
**POSTDOCTORAL
RESEARCH FELLOWSHIP**
supported by S.R.C. in the
**DEPARTMENT OF PURE AND
APPLIED CHEMISTRY**

from mathematicians, physicists or chemists to carry out theoretical studies of dynamical properties of polymer.

Appointment on Range 1A of the national salary structure for research and analogous staff, commencing salary within the range £3,883 to £4,382 with placing according to qualifications and experience. Superannuation benefits.

Duration of appointment will be for two years.

Written applications naming two referees (quoting R42/78) should be sent direct to Dr D. Pugh, Department of Pure and Applied Chemistry, University of Strathclyde, Thomas Graham Building, 295 Cathedral Street, Glasgow G1 1XL, from whom further information can be obtained (tel 041 552 4400, ext 2290) 8167(E).

**UNIVERSITY OF SUSSEX
School of Biological Sciences
POST DOCTORAL
FELLOWSHIP IN
NEUROBIOLOGY**

Applications are invited for a 3 year S.R.C. Postdoctoral Research Fellowship to investigate the neural basis for stimulus localisations by the lateral line system in XENOPUS. Previous neurophysiological experience in recording from the central and peripheral nervous system is required and some knowledge of techniques in the field of developmental neurobiology is desirable.

Salary on the Research Fellow Grade 1A Scale £3,883 to £6,555 p.a. (under review) with superannuation benefits.

Applications, giving details of age, qualifications and experience, together with the names of 2 referees, should be sent as soon as possible to Dr I. J. Russell, School of Biological Sciences, University of Sussex, Falmer, Brighton, Sussex, from whom further particulars are available (telephone Brighton 606755 ext 480) 8120(E).

**UNIVERSITY OF
SOUTHAMPTON
CRYOGENICS RESEARCH
POSTDOCTORAL FELLOWSHIP**

Applications are invited for the following post commencing as soon as possible for one year in the first instance.

**HELIUM REFRIGERATION
IN THE ROTATING FRAME**

To study heat transfer and fluid behaviour of helium at 3000 r.p.m. and develop stable refrigeration cycles for larger superconducting machines. A 1 meter rotating cryostat is available for experimental studies.

Applicants should have experience in mechanical/chemical engineering or low temperature physics.

Salary in range of £3,883 to £5,367 per annum.

Applications, giving details of age, experience, etc., and naming two referees should be sent to D. A. S. Copland, The University, Southampton SO9 5NH quoting reference 383/R/Na. 8128(E).

**UNIVERSITY OF GLASGOW
DEPARTMENT OF GENETICS
M.R.C. POSTDOCTORAL
FELLOWSHIP**

Applications are invited for a M.R.C.-funded Postdoctoral Research Fellowship to study the antigenic composition of the human trophoblast (placental) plasma membrane and relevance to immunological relations between mother and fetus. The facilities and expertise of the Institute of Genetics in cell hybridisation will be used to make monoclonal antibodies against placental antigens. Applicants should have experience in biochemistry, immunology, or immunohistochemistry.

Starting salary according to age and qualifications up to £4,382 p.a. on range 1A of the salary scale Research and Analogous Staff.

Enquiries and applications, including two copies of curriculum vitae, names and addresses of two referees to Dr R. G. Sutcliffe, Department of Genetics, University of Glasgow G 5JS, U.K.

In reply please quote Reference No. 4267/M. 8147(E).

FELLOWSHIPS

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF PLANT BIOLOGY POSTDOCTORAL FELLOWSHIP

Applications are invited for a Post-doctoral Research Fellowship supported by the Ministry of Overseas Development which is tenable for one year from January 1, 1979 to work on storage of cocoa seeds. Salary in the range £3,883 to £6,555 plus superannuation. Starting salary will not exceed £4,382.

Further particulars are available from the Assistant Registrar, Science and Engineering, P.O. Box 363, Birmingham B15 2TT to whom applications (see copies) including a curriculum vitae and the names and addresses of three referees should be sent by January 10, 1978.

Please quote ref: NK5.

8126(E)

THE ROYAL SOCIETY BRUNO MENDEL FELLOWSHIPS

Applications are invited for Bruno Mendel Fellowships for one year from October 1, 1979, renewable for one year exceptionally two additional years, for postgraduate candidates normally resident in the United Kingdom, The Netherlands, or Israel, to carry out research in medicine or the biomedical sciences at a university, medical research centre or medical school. Ends will normally be at the level of junior research fellowship appointment in the United Kingdom; additional allowances for travel and subsistence may be provided as appropriate. Application forms, received by January 15, 1979, and nominations (revised in May 1976) are available from the Executive Secretary, Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.

8135(E)

UNIVERSITY OF KENT AT CANTERBURY LECTURESHIP AND TUTORIAL FELLOWSHIP IN MICROBIOLOGY

Applications are invited for appointment to a vacant Lectureship and a newly created Tutorial Fellowship. Preference will be given to candidates with research interests in either microbial physiology or microbial ecology. It is expected that the Lecturer will be appointed within the first five points on the salary scale £3,883 to £7,764, and the Tutorial Fellow within the first three points of scale £3,883 to £6,555. The latter is a fixed term appointment normally of three years duration. Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, Canterbury, Kent to whom completed applications should be returned by November 24, 1978. Please quote ref: A38/78.

8118(E)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF PHYSICS CRYOGENICS Research Fellowship

Applications are invited for a three year postdoctoral fellowship to study heat transfer in the reboiler/condensers of cryogenic plant, using model rigs including a full-length test section. Starting salary up to £5,129 per annum plus U.S.S. benefits. Applicants with experience in fluid heat transfer, not necessarily at low temperatures, should send a curriculum vitae with the names of two referees to D. A. S. Copland, The University, Southampton SO9 5NH, quoting reference 156/R./Na.

8131(E)

Science Research Council ANGLO-AUSTRALIAN OBSERVATORY TWO POST-DOCTORAL RESEARCH FELLOWSHIPS

The Anglo-Australian observatory (AAO) comprises the 3.9 metre telescope near Coonabarabran, N.S.W. and a laboratory at Epping near Sydney, Australia.

The U.K. Science Research Council provides two post-doctoral research fellowships tenable at the AAO. Candidates should have strong backgrounds in some branch of physics or astrophysics, including theory. The appointment will normally be for two years to start in October 1979. Extension of the fellowships for a third year will be available if the fellow wishes to spend an additional year at an institution in the U.K. Salary will be based on the U.K. university lecturer scale in the range £3,883 to £7,754 (subject to review in 1979) plus other allowances, fares, etc.

Applications should include:

1. Age, citizenship, country of residence and marital status.
2. Qualifications and experience, including date of Ph.D.
3. Astronomical research projects for which telescope time will be sought. (Sufficient information is required to show that the proposal would be competitive in applications to the panel for the allocation of telescope time).
4. Any instrument development project in which the applicant is particularly interested.
5. When applicant would be available.
6. Names and addresses of three referees.

Applications (Quoting reference RF/NS) should be sent to Miss F. Brandon, Science Research Council, Advance Office, P.O. Box 18, Swindon SN2 1ET, England. Telephone: Swindon 26222, Ext. 2226. Applicants should arrange for the three references to be sent to the above address by the closing date of 5th January, 1979.

8143(E)

STUDENTSHIPS

THE ROYAL SOCIETY JOHN MURRAY TRAVELLING STUDENTSHIP IN OCEANOGRAPHY AND LIMNOLOGY 1979

Applications are invited for the Murray Studentship, open to British citizens under the age of 35, for the purpose of travel and work in oceanography or limnology. This award, which may be held for periods of three months to one year, will in 1978 be up to £1,500, adjusted according to qualifications and place of residence.

Applications are especially invited from workers in oceanography and limnology, as well as in zoology, botany, geology, mathematics and physics, and it will be permitted to the award while receiving a salary from a regular appointment.

Applications receivable by December 1978, should be made on forms available from The Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.

8134(F)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF AGRICULTURAL BIOCHEMISTRY S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited for a C.A.S.E. Studentship in the following topic:

Continuous Fermentation Studies with Rumen Microorganisms

Applicants should have at least an Upper Second Class Honours Degree in either Bacteriology, Microbiology, Applied Biochemistry or a related subject. The project, which is sponsored by I.C.I. Pharmaceuticals will be supervised by Professor D. G. Armstrong and Mr D. G. Harrison, from whom full details are available.

Applications, containing the names of two referees, should be sent to Professor D. G. Armstrong, Department of Agricultural Biochemistry, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU by November 13, 1978.

The studentship must be taken up by March 31, 1979.

8080(A)

MICROBIOLOGY graduate required for a Ph.D. Studentship in connection with a research project on bacteriological aspects of acne. Apply in writing, with full curriculum vitae and the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C.6.

8094(A)

THE UNIVERSITY OF MANCHESTER DEPARTMENT OF BIOCHEMISTRY S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited from good Honours graduates with enterprise, initiative and interests at the interface of Biochemistry and Organic Chemistry to work for three years on the covalent attachment of fluorescent labels to carbohydrates. This is a joint project with the Organics Division of I.C.I. at Blackley, Manchester. The appointment will commence as soon as possible and preferably not later than December 31, 1978. Apply as soon as possible, with curriculum vitae, telephone number, and names and addresses of two referees, to Dr J. S. Thompson, Department of Biochemistry, University of Manchester M13 9PL (Telephone (061) 273 7121, ext. 5232 or 5108).

8085(A)

UNIVERSITY OF SOUTHAMPTON C.A.S.E. Studentship in CRYOGENICS

Applications are invited for a 2 year S.R.C. C.A.S.E. Research Studentship on "Refrigeration cycles for rotating helium at 3000 r.p.m."

Applicants with a good degree in Physics or Engineering should write to Dr R. G. Seurlock, Physics Department, University of Southampton, as soon as possible. Please quote ref: MA1/2/Na.

8127(A)

UNIVERSITY OF MANCHESTER DEPARTMENT OF BACTERIOLOGY AND VIROLOGY

The North West Water Authority is funding a three-year postgraduate studentship in microbiology which will be primarily concerned with the development of standard methods for the quantitative estimation of salmonellae strains in sewage sludge. Maintenance grant payable: £1,860 per annum.

The successful candidate will register for a higher degree, probably at M.Sc. level for one year but renewable for a further two years for a Ph.D. subject to satisfactory academic progress. The award is tenable as soon as possible. Particulars from the Registrar, The University, Manchester M13 9PL (quote ref. 244/78/N) to whom letters of application should be sent by November 14.

AWARDS

Awards for RESEARCH INTO TROPICAL RESPIRATORY DISEASES

The Wellcome Trust wishes to encourage research into diseases of the respiratory system, including asthma, occurring in the tropics. A competitive award of up to £100,000 is offered for a period of not more than five years. Preference will be given to proposals which demonstrate an interdisciplinary approach and especially those which include sustained collaboration with research centres in the tropics.

Applications for smaller awards will also be considered and grants may also be made to the runners up. *These awards are additional to the Trustees' normal arrangements for supporting tropical medical research.*

Those wishing to apply should send a two-page summary of their objectives and proposals for research, including a brief estimate of the anticipated costs, for preliminary consideration. The principal scientist should also send a curriculum vitae.

Applications should be addressed to **Mr. M. A. F. Barren, The Wellcome Trust, 1 Park Square West, London NW1 4LJ, and reach the Trust by 8th December 1978.**

The Wellcome Trust

CONFERENCES

CONFERENCE

Third International Conference on the Chemistry and Uses of Molybdenum

sponsored by the University of Michigan and Climax Molybdenum Co. Ann Arbor, Michigan, U.S.A., August 19-23, 1979.

Application forms can be obtained from:

Climax Molybdenum Co. Ltd.,
Imperial House,
1/3 Grosvenor Place,
London SW1X 7DL. 8034(C)

FOR SALE & WANTED

J. Physiol. Vols 107 (1948) to 198 (1968) and 236 (1974) to 282 (1978). Offers to Box No. 8144(L) Macmillan Journals Ltd., 3 Dyers Buildings, Holborn EC1N 2NR. 8144(L)

ATMOSPHERIC PRESSURE RECORDS

If you have any such records in any form for any part of the world, for any part or all of any of the periods listed below, please send a copy to Dr B. W. Jones, Faculty of Science, The Open University, Milton Keynes MK7 6AA, Gt. Britain. Reasonable expenses can be recovered. *Periods:* March 1 to 14, 1970; July 4 to 17, 1972; June 24 to July 7, 1973; June 14 to 27, 1974; October 17 to 30, 1976; October 6 to 19, 1977. 8157(L)

SYMPOSIA

THE SECOND INTERNATIONAL SYMPOSIUM ON MICROBIAL ECOLOGY

will be held
at the University of Warwick,
Coventry, England
September 7-12, 1980

For information and a copy of the First Circular, contact: Dr M. Fletcher, Department of Environmental Sciences, University of Warwick, Coventry CV4 7AL, England. 8078(M)

SYMPOSIA

INTERNATIONAL PEPTIDE SYMPOSIUM

The Intramural Program of the National Institute of Neurological and Communicative Disorders and Stroke will sponsor an International Symposium entitled "The Role of Peptides in Neuronal Function" to be held May 7-9, 1979, at the National Institutes of Health reservation in Bethesda, Maryland. The three-day meeting will draw together investigators from diverse disciplines for a comprehensive review of peptide research as it relates to the field of neurobiology.

The first day will include presentations on the anatomy and physiology of peptidergic neurons, as well as the synthesis and secretion of peptides. The second day will begin with a discussion of peptide-mediated communication in the nervous system, followed by reviews of the neurobiology of specific peptides, including angiotensin, neurotensin, somatostatin, substance P, vasoactive intestinal peptide, luteinizing hormone releasing hormone, thyrotropin releasing hormone, olfactory system peptide, bag cell hormone and neurodepressing hormone. The final day will be devoted entirely to the pharmacology, physiology and potential clinical application of opioid peptides.

The Symposium is being organised by Drs Jeffery Barker and Thomas Smith of the N.I.N.C.D.S. Laboratory in Neurophysiology.

Those interested in attending should contact either Dr Barker or Dr Smith, Bldg. 36, Room 2C02, National Institutes of Health, 9000 Rockville Pike, Bethesda, Md. 20014. Tel: 301-496-2414. 8168(M)

GRANTS

THE ROYAL SOCIETY BROWNE RESEARCH FUND MAURICE HILL RESEARCH FUND MARSHALL AND ORR BEQUEST Grants 1979

The Council of the Royal Society invites applications from qualified research workers for personal grants:

(a) from the Browne Research Fund, for research in marine biology at a marine biological laboratory or elsewhere. Preference will be given to those who propose to work on purely scientific problems rather than to those whose work would be primarily directed towards an economic end.

(b) from the Maurice Hill Research Fund (established in memory of the late Dr M. N. Hill, F.R.S., for the encouragement of research in physical oceanography and marine geophysics) for research at sea and/or in the laboratory in physical and chemical oceanography, marine geophysics and geology.

(c) from the Marshall and Orr Bequest for the support of marine biological research.

Grants may be used for periods up to one year, and are made on the understanding that university or other posts held by applicants will meanwhile be kept open for them. Recipients are permitted to use grants while receiving salaries from regular appointments.

In 1979 the total amounts available to be shared among all successful applicants will be about £4,250 from the Browne Research Fund, £8,400 from the Maurice Hill Research Fund and £7,820 from the Marshall and Orr Bequest; individual grants will not ordinarily be more than £750.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AC, and returned by December 15, 1978. 8136(A)

COURSES

EMBO LABORATORY COURSE

ON

"Plasmids—A Course in Advanced Techniques"

April 9-29, 1979

UNIVERSITY OF
ERLANGEN, GERMANYOrganisers: Kenneth Timmis and
Alf Pühler

The course will consist of laboratory experiments and lectures designed to instruct participants in the use of recently developed methods that are particularly important for the structural and functional analysis of plasmid genomes. These will include transposition mutagenesis, gene cloning, the uses of restriction enzymes, electron microscopy and DNA sequencing for structural analysis, the uses of minicells and *in vivo* systems for studying plasmid expression and replication.

A mini-symposium on the "Plasmids of Medical, Environmental and Commercial Importance" will follow the laboratory course.

Applications, with a short curriculum vitae including future scientific interests, and any information which might help in their evaluation should be sent in duplicate to:

Professor A. Pühler
Institute of Microbiology and
Biochemistry
University of Erlangen
Friedrichstr. 33
D 8520 Erlangen, FRG 8109(I)

NATO ASI

NUCLEOSIDE ANALOGUES: CHEMISTRY, BIOLOGY AND MEDICAL APPLICATIONS

May 7-18, 1979

Sogesta, nr. Urbino, Italy

This interdisciplinary Study Institute will be directed towards the *Structural synthesis and chemical reaction nucleosides, their evaluation and as antiviral and anticancer drugs.* The programme will include review lectures, research seminars and discussion periods.

The lecturers will include: J. van Boom (Netherlands), Y.-C. C. (USA), S. S. Cohen (USA), S. Danyluk (USA), T. C. Merigan (U.S.), J. G. Moffatt (USA), W. H. P. (USA), M. J. Robins (Canada), Saenger (Germany), F. M. S. (USA), R. W. Sidwell (USA), L. Townsend (USA), H. Vorbrüggen (Germany).

Applications should reach Dr R. Walker, Department of Chemistry, Birmingham University, P.O. Box, Birmingham B15 2TT, UK, at or not later than December 1, 1978.

They should contain a short background and interests and a letter of recommendation where appropriate. Research seminars to be presented by applicants. A short abstract of contributions should accompany application. The number of participants will be limited to 60 and everyone is expected to attend for the duration of the course.

Successful applicants will have to provide a non-refundable deposit of US\$100 (which will then be deducted from the living expenses of ~\$390) limited number of stipends, to cover partially the living expenses and travel costs are available but participants are encouraged to cover their expenses from the resources of their institutions wherever possible. 8158(I)
